KEY TO PRONUNCIATION.

ā	as in ale, fate. Also see ǎ , below.	D	as in the Spanish Almodovar, <i>pulgada</i> , where it is nearly like <i>th</i> in English <i>then</i> , this.
ā	“ “ senate, chaotic. Also see ǎ , below.	g	“ “ go, get.
ā	“ “ glare, care.	G	“ “ the German Landtag, and <i>ch</i> in <i>Feuerbach</i> , <i>buch</i> ; where it is a guttural sound made with the back part of the tongue raised toward the soft palate, as in the sound made in clearing the throat.
ā	“ “ am, at.	H	as <i>j</i> in the Spanish <i>Jijona</i> , <i>g</i> in the Spanish <i>gila</i> ; where it is a fricative somewhat resembling the sound of <i>h</i> in English <i>hue</i> or <i>y</i> in <i>yet</i> , but stronger.
ā	“ “ arm, father.	hw	“ <i>wh</i> in which.
ā	“ “ ant, and final <i>a</i> in <i>America</i> , <i>armada</i> , etc. In rapid speech this vowel readily becomes more or less obscured and like the neutral vowel or a short <i>u</i> (ǔ).	K	“ <i>ch</i> in the German <i>ich</i> , <i>Albrecht</i> , and <i>g</i> in the German <i>Arensberg</i> , <i>Mecklenburg</i> ; where it is a fricative sound made between the tongue and the hard palate toward which the tongue is raised. It resembles the sound of <i>h</i> in <i>hue</i> , or <i>y</i> in <i>yet</i> ; or the sound made by beginning to pronounce a <i>k</i> , but not completing the stoppage of the breath. The character K is also used to indicate the rough aspirates or fricatives of some of the Oriental languages, as of <i>kh</i> in the word <i>Khan</i> .
a	“ “ final, regal, where it is of a neutral or obscure quality.	n	as in <i>sinker</i> , longer.
a	“ “ all, fall.	ng	“ “ sing, long.
a	“ “ eve.	N	“ “ the French <i>bon</i> , <i>Bourbon</i> , and <i>m</i> in the French <i>Etampes</i> ; where it is equivalent to a nasalizing of the preceding vowel. This effect is approximately produced by attempting to pronounce ‘onion’ without touching the tip of the tongue to the roof of the mouth. The corresponding nasal of Portuguese is also indicated by N , as in the case of <i>São Antão</i> .
æ	“ “ elate, evade.	sh	“ “ shine, shut.
æ	“ “ end, pet. The characters ě , ā , and ǎ are used for ä in German, as in <i>Gärtner</i> , <i>Gräfe</i> , <i>Hähnel</i> , to the values of which they are the nearest English vowel sounds. The sound of Swedish ä is also indicated by ě .	th	“ “ thrust, thin.
ě	“ “ fern, her, and as <i>i</i> in <i>sir</i> . Also for ö , oe , in German, as in <i>Göthe</i> , <i>Goethe</i> , <i>Ortel</i> , <i>Oertel</i> , and for <i>eu</i> and <i>oeu</i> in French, as in <i>Neufchâtel</i> , <i>Crêvecœur</i> ; to which it is the nearest English vowel sound.	TH	“ “ then, this.
e	“ “ agency, judgment, where it is of a neutral or obscure quality.	zh	as <i>z</i> in <i>azure</i> , and <i>s</i> in <i>pleasure</i> . An apostrophe ['] is sometimes used to denote a glide or neutral connecting vowel, as in <i>tā'b'l</i> (<i>table</i>), <i>kāz'm</i> (<i>chasm</i>).
i	“ “ ice, quiet.		Otherwise than as noted above, the letters used in the respellings for pronunciation are to receive their ordinary English sounds.
i	“ “ quiescent.		When the pronunciation is sufficiently shown by indicating the accented syllables, this is done without respelling; as in the case of very common English words, and words which are so spelled as to insure their correct pronunciation if they are correctly accented. See the article on PRONUNCIATION .
i	“ “ ill, fit.		
ī	“ “ old, sober.		
ō	“ “ obey, sobriety.		
ō	“ “ orb, nor.		
ō	“ “ odd, forest, not.		
o	“ “ atom, carol, where it has a neutral or obscure quality.		
oi	“ “ oil, boil, and for <i>eu</i> in German, as in <i>Feuerbach</i> .		
oo	“ “ food, fool, and as <i>u</i> in <i>rude</i> , <i>rule</i> .		
ou	“ “ house, mouse.		
ū	“ “ use, mule.		
ū	“ “ unite.		
ū	“ “ cut, but.		
ū	“ “ full, put, or as <i>oo</i> in <i>foot</i> , <i>book</i> . Also for ü in German, as in <i>München</i> , <i>Müller</i> , and <i>u</i> in French, as in <i>Buchez</i> , <i>Budé</i> ; to which it is the nearest English vowel sound.		
û	“ “ urn, burn.		
y	“ “ yet, yield.		
B	“ “ the Spanish <i>Habana</i> , <i>Cordoba</i> , where it is like a <i>v</i> made with the lips alone, instead of with the teeth and lips.		
ch	“ “ chair, cheese.

THE NEW INTERNATIONAL ENCYCLOPÆDIA

P**HILADELPHIA** (Lat., from Gk. *Φιλαδέλφεια*, *Philadelphēia*, named in honor of Attalus Philadelphus). A city of Asia Minor, now called Alashehr (the 'reddish city,' from the color of the hillsides in the rear), situated in the valley which runs inward from the Gulf of Smyrna, about 75 miles east by south of Smyrna (Map: Turkey in Asia, C 3). The city was founded in the second century B.C. It lay on the trade routes from the interior to the coast and assumed a position of commercial importance. Its name was changed at different times, as shown by the coins of Roman emperors, and it was a point of considerable importance in the political affairs of the Province of Asia. Philadelphia was the head of a district in which Christian churches were established very early, since messages were sent to it in the Book of Revelation (iii. 7-13). Little is known concerning the number or size of these churches. Philadelphia bore a conspicuous part in later history, figuring as a bulwark against the Turks. See ALASHEHR.

PHILADELPHIA. The chief city of Pennsylvania, and the third city in population and importance of the United States, co-extensive with Philadelphia County, having an area of 129.5 square miles. It is situated in the southeastern corner of the State, at the confluence of the Schuylkill with the Delaware, about 50 miles from the mouth of the Delaware and 100 miles from the Atlantic Ocean, in latitude 39° 57' N. and longitude 75° 9' W. It is distant from New York by rail 90 miles, from Washington 132, and from Chicago 822.

The climate of Philadelphia is considerably milder in winter and warmer in summer than that of the central and western cities of the State. The mean temperature for January is 32.3°, and for July 76.2°. The heat during July and August is often very intense, the temperature rising sometimes above 100°. The average annual rainfall in the city is about 44 inches, slightly heavier than that of New York.

DESCRIPTION. William Penn founded the city on the narrow neck of land, some two miles wide, lying between the Delaware and Schuylkill

ivers. Disregarding his plan for a simultaneous growth of the city backward from each river, the early settlers preferred to remain near the Delaware, along which occurred the first north and south expansion of the city. It was not until the beginning of the nineteenth century that the westward growth of the city reached Broad Street, the half-way line to the Schuylkill. From this time on the city has grown more rapidly, extending southward to the junction of the two rivers, westward far beyond the Schuylkill to Cobb's Creek, and northward in two main branches, the easternmost following the Delaware to Poquessing Creek, eighteen miles from the southern limit, and the westerly through the suburban region stretching ten miles along the Wissahickon—a tributary of the Schuylkill. In the western and northern sections of the city large areas of open country still exist. From the dike-protected lowlands of the south, five feet below the average high tide, the city rises gradually to heights of 443 feet in the hilly regions of the northwest. The general plan of the streets is determined by the east and west direction of Market Street, the main business thoroughfare, 100 feet wide, which runs directly west from the Delaware, a distance of six miles, separating the city for the purpose of street numbering into north and south divisions; and by Broad Street, 113 feet wide and 12 miles long, which at City Hall Square intersects Market at right angles. The main portion of the city is laid out with great regularity, the numbered streets running parallel with Broad, and the named streets with Market. The regularity of the general plan is broken, however, in the portion east of the Schuylkill, by Ridge and Germantown avenues, which intersect diagonally the streets north of Market, and by Passyunk and Moyamensing avenues, south of Market Street; in West Philadelphia, Lancaster Avenue, north, and Woodland Avenue, south of Market Street, act in a similar manner, though in this and in other outlying sections there is, in general, less attempt to follow strictly the regularity of the older portions of the city. There are more than 1560 miles of streets, of which

some 900 miles are paved with brick, stone, or asphalt, 225 macadamized, and the remainder unpaved. The mileage of sewers is 951 and of water mains 1319. The street railways (employing the overhead trolley system, and in 1902 carrying 325,801,963 passengers) have a total mileage of 475, and the steam railroads of 360. At the present time (1903) there is under construction a subway system of four tracks from the Delaware to the Schuylkill, with an elevated extension along Market Street from the Schuylkill to the city line. Twelve public and twelve railroad bridges cross the Schuylkill, and one railroad bridge the Delaware; and among these are some of the finest structures of the kind in the country.

It is possible to characterize with tolerable accuracy the various sections of Philadelphia. The business life centres around Market Street. The portion north and south of this thoroughfare bordering the Delaware is devoted to wholesale trade, shipping, and warehouses; from Third Street to Eighth, Market, Chestnut, and Walnut may be designated as the financial and banking centre of the city; these streets, with Arch, from Eighth to City Hall, form the great retail shopping section, where are found the great department stores. The large office buildings cluster about the City Hall, at the junction of Broad and Market Streets, in the vicinity of which are also found the Pennsylvania and Reading depots and the Baldwin Locomotive Works. Westward from the City Hall, Market Street is lined by smaller wholesale and retail establishments; while beyond the Schuylkill, Lancaster and Woodland avenues dispute its supremacy in retail trade. The northeastern section, comprising Kensington and Frankfort, and certain portions of the northwest section form the chief textile centre of the city; the northeast section at Port Richmond is also the location of Cramp's ship-yards. The southern portion, east of the Schuylkill, is devoted to general manufactures and to transportation.

The residential portions of the city seem to be as clearly divided by Market Street as are the business interests. South of that thoroughfare, on Chestnut, Walnut, and Spruce streets, centring about Rittenhouse Square, is the aristocratic residential section of the city. North of Market the upper portion of Broad Street, with portions of other streets between it and the Schuylkill, forms another important residence area. North of this comes the residential section occupied largely by textile operatives. South of Market and extending a few blocks below Lombard is the section occupied by the foreign and colored elements, with the former, consisting largely of Italians and Hebrews, grouped to the east of Broad, and the negroes between Broad and the Schuylkill. In this region are located most of the slums of the city, though the peculiarities of the building plan permit them to exist in the rear of the best residential sections. West of the Schuylkill, Market Street continues to divide West Philadelphia into two distinct residential portions; for the northern the character is largely determined by the proximity of the main freight yards of the Pennsylvania Railroad, whose employees, together with employees from the downtown business district, constitute the bulk of its population. The southern is a

more pretentious residence district, with many notable residences and with an academic air imparted to it by the presence of the University of Pennsylvania. Especially noted for their villas and gardens are the attractive suburbs of Germantown and Chestnut Hill; and in the general beauty of its numerous suburban sites Philadelphia is unsurpassed by any city of the world.

By its name Philadelphia suggests its distinctive title "The City of Brotherly Love;" its early history renders especially appropriate that of "the Quaker City;" but none more truly characterizes it than that of "The City of Homes." Of 323,783 buildings of all kinds (1903), 298,144 are dwelling houses, with an average of 4.5 persons per dwelling, and with 22 per cent. owned by the occupants. There are 800 church buildings, 474 schools, public and private, and 247 buildings used for charitable and benevolent purposes. In the older portions there are many survivals of the long blocks of red brick houses, with white marble steps and trimmings, that early gave Philadelphia the neat appearance for which it is still famous. In the newer portions red brick is still the principal building material, and the residences are commonly built in long blocks of houses of four or more similarly arranged rooms, each separated from its neighbors by a brick party-wall, and varying in size with the width of the street. On some of the larger streets the houses are built in pairs, instead of blocks, but the arrangement of the separate houses is the same. There is, however, a more welcome variety in styles of architecture than formerly, and various kinds of building stone, along many streets, are beginning to break the monotony of the customary brick, while in the better suburbs the residences are almost wholly of stone or wood. In general, Philadelphia, in its homes and parks, may be said to retain to a greater degree than any other large American city the finer qualities of its early town life and to combine with these the best features of modern industrial development.

BUILDINGS. Adherence to an early architectural idea has made Philadelphia one of the last of large American cities to favor tall buildings. Very recently, however, a group of tall structures has sprung up in the vicinity of the 'Public Buildings,' as Philadelphians designate their City Hall. This immense structure, begun in the early 70's, and covering 4½ acres, accommodates all the municipal and county officers, and the State and county courts. It is a marble edifice, of modern French Renaissance style, 90 feet high, rising in corner pavilions to 161 feet, in central pavilions to 203 feet, and in the tower surmounted by a colossal statue of Penn 37 feet high and weighing 53,348 pounds) to a height of 547 feet 11¼ inches. The building, inclosing a large central court, measures 486 feet 6 inches by 470 feet, and in it are 634 rooms, with a floor space of 14½ acres. In the tower are four great clock dials, each with a minute hand eleven feet long and weighing 225 pounds, and regulated by a vibration and temperature proof clock 143 feet below. The cost of the Public Buildings up to December 31, 1902, was \$24,344,350, of which some \$18,250,000 was for construction proper.

Among the important Federal buildings located within the city are the new United States Mint, on Spring Garden Street, one of the largest and most completely equipped in the world; the Post

Office Building, bounded by Market, Chestnut, Tenth and Ninth, occupying the site of the first President's Mansion and the subsequent home of the University of Pennsylvania; the Custom House, on Chestnut Street near the Delaware, modeled after the Parthenon, and erected in 1819-24 for the Second United States Bank; the Arsenal, below South Street near the Schuylkill; and at the southern end of Broad Street, the large League Island Navy Yard. Of the historic buildings the most important are the familiar Independence Hall and Carpenter's Hall on Chestnut Street, inseparably associated with the early Continental and Federal Congresses; the Betsy Ross House on Arch Street, where the first American flag was made; the Old Swedes (1700) and Old Christ (1727) churches of Revolutionary fame; and the first United States Mint, on Seventh Street below Market. The Pennsylvania Historical Society, one of the strongest organizations of its kind in the country, has an elegant building at Thirteenth and Locust streets.

Now that Philadelphia has adopted the modern steel frame building (with a careful regulation of height, however), its recent business structures will compare favorably in size and importance with those of any other American city. Among the leading office buildings may be mentioned the Land Title Annex (319 feet high); the pioneer Betz Building; the Real Estate Trust Building; the Arcade Building, and the Commonwealth Trust Building—all grouped around the City Hall; and the Real Estate Title and Trust Company Building, the Drexel Building, the Bullitt Building, and the Provident Building—notable structures of the financial area. In this vicinity, also, is the Philadelphia Contributionship 'Hand in Hand,' the oldest fire insurance company in America, of whose directorship Franklin was an early member. The Pennsylvania Railroad station, with a train shed over 700 feet long, and the Reading Terminal, a handsome railroad station, approached like that of the Pennsylvania Railroad by a viaduct, are notable railway terminals and office headquarters. Of newspaper buildings the most prominent are those of *The North American* (22 stories), *The Record*, and *The Public Ledger*. Of semi-public organizations the Stock Exchange is housed in the remodeled Merchants' Exchange Building; the Bourse Building is the home of the Board of Trade, the Trades League, and other trade organizations; and the Commercial Museum, supported by municipal, State, and Federal appropriations, and devoted to the encouragement of foreign commerce, especially with Spanish America, is located temporarily on Fourth Street, pending the erection of a permanent structure in West Philadelphia, on the site of the Exposition of 1899. Philadelphia has many important hotels, among the most elegant and commodious of which may be mentioned the Walton and the new Bellevue-Stratford, both on Broad Street near City Hall.

With structures representing interests that are not strictly utilitarian Philadelphia is well supplied. The Masonic and Odd Fellows' temples, on North Broad Street, rank with the best society structures on the continent. The Young Men's Christian Association Building on Fifteenth Street, that of the Young Women's Christian Association on Arch street, the Crozier Building of the Baptist Publication Society, the Witherspoon Building, with the publication

rooms, general offices, and historical museum of the Presbyterian Church (North), represent in highest perfection the application of modern business methods to religious work. In addition to the historic churches already mentioned, the most important edifices are the Roman Catholic Cathedral, the Kenneth Israel Synagogue, and the Baptist Temple of North Broad Street, Holy Trinity (Protestant Episcopal) on Rittenhouse Square, the Arch Street (Methodist Episcopal), the First Presbyterian and the Tabernacle Presbyterian and the Friends' Meeting House on Arch Street—the Quaker Westminster of America. Of educational institutions the University of Pennsylvania, Drexel Institute, the new Boys' High School, Girard College with its early Grecian structures, and the Roman Catholic High School are architecturally of importance.

PARKS. The system embraces about 4000 acres. Public interest has been aroused of late in the development also of parkways. William Penn expressed the desire to make Philadelphia a 'greene country towne,' and his surveyor Holme placed on the plan, near its four angles, rectangular open spaces, now Logan (northwest), Rittenhouse (southwest) Franklin (northeast), and Washington (southeast) squares, containing an aggregate of 28½ acres. These, together with Central Square, the site of the original water-works, but now of City Hall, formed a cherished precedent. In 1903 there were under the care of the Bureau of City Property more than 50 small parks and plots containing over 600 acres. The largest was League Island Park (300 acres), contiguous to the League Island Navy Yard. In Independence Square the Declaration of Independence was read to the populace. Penn Treaty Square marks the site of the great elm under which, according to tradition, the founder made his famous compact with the Indians. In Logan Square was held in the summer of 1864 the great Sanitary Fair. Bartram's Garden (27 acres), on the banks of the Schuylkill, was the first botanical garden in the New World. Its noteworthy arboreal collection has been preserved.

The city's greatest pleasure ground is Fairmount Park, rich in natural beauties. The Schuylkill divides it into East Park, with over 633 acres, and West Park, with 1323 acres. Along the Wissahickon is the Wissahickon Valley extension of 1010 acres. The acquisition in 1812 of five acres on Morris's Hill, the original Fair Mount, for water-works and park purposes, led to the formation of the park. To this were added areas of woodland, and country seats, the Lansdowne estate of Governor John Penn, Eaglesfield, Sweet Briar, and Solitude; the Belmont home of Judge Peters of the Supreme Court, where Washington, Franklin, Jefferson, Lafayette, and others visited; Mount Pleasant, the residence of Benedict Arnold; George's Hill (83 acres), presented by Jesse and Rebecca George; Strawberry Mansion, Lemon Hill, Ormiston, and Edgely. The miniature Letitia House, built by William Penn for his discontented daughter, was transported from the city. The Zoological Gardens are maintained by private subscription, admission receipts, and municipal appropriations contingent upon the free admission of school children. The Centennial Exposition of 1876 brought many noteworthy structures into the park, the most important that remain being Horticultural Hall, with a fine exotic collection, and Memorial Hall,

where are exhibited the Wiltach Art Collection and the display of the Pennsylvania Museum and School of Industrial Art. A trolley line, below grade, eight miles long, extends to the chief points of attraction. A speedway, one mile in length, is being completed. The Schuylkill is frequently the scene of regattas, and there are handsome stone boat houses on its eastern bank.

Many fine monuments have been placed in the park. The Washington Monument by Siemering of Berlin is the most imposing. Funds for its erection were provided by the Society of the Cincinnati, the subscriptions, begun in 1819, aggregating \$250,000 when the monument was unveiled in May, 1897. It stands at the Green Street entrance, the termination of the Park Boulevard. This thoroughfare, projected in 1903, is to be 160 feet wide from City Hall to Logan Square, and thence 300 feet wide to the park. In the same year was authorized the construction of the Torresdale Boulevard, 300 feet wide and 15 miles long, from North Broad Street to Torresdale. Of note are the statues of Lincoln, Garfield, Grant, Meade, Humboldt, Schiller, Goethe, Columbus, Joan of Arc, Witherspoon, and Father Matthew; and the Catholic Total Abstinence Union Fountain, and the Smith Memorial Arch. Grant's Cabin, occupied as headquarters at City Point, is here preserved. In the city proper are comparatively few works of art, the most important being statues of Washington in front of Independence Hall, of Franklin on the post-office pavement, and of McClellan and Reynolds on City Hall Plaza.

The Wissahickon Valley, a deep wooded ravine, which has been left almost in its original wild state, is of interest for its memories and legends of Indian braves and mystic German monks who made it their retreat. The first paper mill in America was erected on its banks in 1690. In Fairmount Park there are 20 small streams, several lakes, and more than 150 springs; over 66 miles of drives, 10 of bridle paths, and 40 of smaller roads. The boundary line is 30 miles long. The entire cost approximates \$7,000,000, and \$3,500,000 has been expended in permanent improvements.

The Laurel Hill cemeteries are contiguous to the park. In the city are numerous burial places, many of historic associations.

EDUCATIONAL INSTITUTIONS AND LIBRARIES. At the close of 1902 there were in the city six higher schools, including a high school for boys, conferring degrees of A.B. and B.S., and a school of pedagogy; a high school, a commercial high school, and a normal school for girls; and two manual training schools. There were also one school of industrial art, one elementary manual training school, one observation and practice school, five special schools for backward children and truants (under the compulsory education law), twelve cooking schools, and grammar, primary, and kindergarten schools, making the total of city institutions 420, with 229 male and 3537 female teachers, and an attendance of 158,473, of which 5800 were in the higher schools. The general course of study falls under no classification, but is the result of development. Foreign languages are taught only in the higher schools. There is some special and experimental manual training for seventh and eighth grade boys, and cooking and sewing instruction for sixth, seventh, and eighth

grade girls. Through private bequest and municipal legislation there are available 358 free scholarships in the University of Pennsylvania, Bryn Mawr, Lehigh University, and various medical, art, and scientific colleges. Night and summer vacation schools are conducted.

At the head of the higher educational institutions is the University of Pennsylvania (q.v.). Philadelphia is a centre of medical education, its prominent medical colleges being that of the University of Pennsylvania, Jefferson, Hahnemann, Medico-Chirurgical, Polyclinic, and Woman's (founded in 1850), the first chartered medical college for women in the world to confer the degree of M.D. The Pennsylvania and Philadelphia dental colleges (the oldest and the best of their kind) and the Philadelphia College of Pharmacy are largely attended. The art schools of the Pennsylvania Academy also are the oldest in the country. The School of Industrial Art and the School of Design for Women are well known. Bryn Mawr College (q.v.), near Philadelphia, is one of the foremost women's institutions of the United States. The Drexel Institute, founded and endowed with \$2,000,000 by A. J. Drexel, offers at a small cost courses in art, sciences, and industrial training. Other leading institutions are the Franklin and Spring Garden Institutes, Temple College, Episcopal Academy, the seminaries of the Protestant Episcopal, Lutheran, and Roman Catholic churches, La Salle and Saint Joseph's Colleges, and the Roman Catholic High School, the Methodist Episcopal Collegiate Institute for Girls, numerous schools of the Society of Friends, including the William Penn Charter (1701), the first chartered school in the country, the Cheltenham Military Academy, and the Germantown Academy (1760). The Williamson Free School of Mechanical Trades, established under a bequest of \$2,500,000 by the late I. V. Williamson, offers complete trade courses and supports students free of cost. Philadelphia is noted for its associations and institutions for the promotion and diffusion of science and learning, and the encouragement of art. Among these are the Philadelphia Academy of Natural Sciences (q.v.), the Franklin Institute (q.v.), the American Philosophical Society, the American Academy of Political and Social Science, the Historical Society of Pennsylvania, the Zoological Society, the Numismatic and Antiquarian Society, the Pennsylvania Academy of Fine Arts, and the Wagner Institute.

The Free Library, now in temporary quarters, founded in 1891, on bequests of George S. Pepper and others, is maintained by appropriations made by City Councils. In the central and 14 branch libraries are over 250,000 volumes. A gift by Andrew Carnegie of \$50,000 for each of thirty additional branches with halls for public gatherings (conditional upon their maintenance by the city), and an appropriation of \$1,000,000 for a permanent central building, provided by a loan approved by popular vote, are awaiting expenditure. The Library Company's collection, begun in 1731 by Benjamin Franklin and his associates of the 'Junto,' formed the first subscription library in America. Its 200,000 volumes include many of extreme rarity. The Ridgway Branch, an excellent example of pure Greek architecture, contains one of the most valuable reference lists in the United States. Other important libraries

CITY HALL

PHILADELPHIA

INDEPENDENCE HALL

of the 100 in the city are the Mercantile (1821), general circulation and reference; Carpenters' Company (1736), architecture and building; Friends' (1742); American Philosophical Society (1743); Academy of Natural Sciences; Franklin Institute, scientific; Hurst, law; College of Physicians; University of Pennsylvania, Apprentices', Pennsylvania, Presbyterian, and Baptist Historical societies; Drexel Institute; and the H. Josephine Widener Branch of the Free Library, with a valuable collection of reference works.

HOSPITALS AND OTHER INSTITUTIONS. The municipal charities are the hospitals for the Indigent and for the Insane, General Hospital, and the Municipal Hospital (contagious diseases). The Pennsylvania Hospital, founded in 1751, through the efforts of Franklin, and maintained entirely by private subscription, is the oldest institution of the kind in America. The religious denominations maintain institutions, among them being Saint Agnes', Saint Mary's, and Saint Joseph's hospitals (Roman Catholic); Episcopal, Methodist, Presbyterian, Jewish, Saint Luke's (Baptist), and German (Lutheran) hospitals. Large hospitals are connected with the University, and Jefferson, Medico-Chirurgical, Polyclinic, Hahnemann, and Woman's Medical colleges. Other important charities are the Rush and Phipps hospitals for consumptives, the Gynceean, Orthopaedic, Wills Eye, and Maternity hospitals. There are more than 100 dispensaries, homes, asylums, orphanages, etc. The College Settlement, Society for Organizing Charity, Working Women's Guilds, Flower, Fruit, and Ice Mission, various children's aid, protection, and country week associations do good work. The city maintains numerous public baths, which were patronized in 1902 by 4,453,000 persons.

Girard College, founded by Stephen Girard, who at his death in 1830 gave \$2,000,000 for construction and the greater portion of his \$5,000,000 estate for endowment, supports and educates annually over 1600 orphans. The residuary fund now amounts to \$16,500,000. The Citizens' Permanent Relief Committee has relieved thousands of distressed in all parts of the world, over \$5,000,000 having been distributed since 1879. The Mayor is president. The penal institutions are the Eastern State Penitentiary, the House of Refuge (boys and girls), the House of Correction (adults), and Moyamensing and Holmesburg County prisons.

THEATRES AND CLUBS. The drama in America began in Philadelphia, a company being organized in 1749. The first permanent playhouse in the city was built in 1766; a portion of its walls still stands. The Walnut Street Theatre is the oldest in the country. At Locust and Eighth streets stands the Musieal Fund Hall, where Malibran, Jenny Lind, and Ole Bull appeared. Other important playhouses are Keith's New Theatre, the Garrick, the South Broad, the Chestnut Street, the Grand and Chestnut Street opera houses, and the Auditorium. The Academy of Music, with a capacity of 2900, is used for large public gatherings.

Leading clubs are the Union League, with a handsome brownstone building, Philadelphia, Manufacturers', Mercantile, Rittenhouse, Markham, Columbia, University, Penn, the Art, installed in a beautiful Renaissance structure of Pompeian brick and Indiana limestone, Sketch,

Lawyers' Clover, Five o'Clock, Maennerchor, Franklin, Country, Pen and Pencil, Philadelphia Yacht, and the New Century and Acorn (women's).

COMMERCE AND MANUFACTURES. The industrial development of Philadelphia has been greatly aided by the favorable location of the city for commerce, and especially by its proximity to raw materials. The city has the advantage of superior railroad facilities. The great Pennsylvania Railroad system, with 10,484 miles of owned and leased lines, and the Philadelphia and Reading Railway, with \$140,000,000 capital and 1457 miles of track, terminate and have home offices near the City Hall. The Pennsylvania lines give Philadelphia more direct communication with the productive Middle West than is enjoyed by any other Atlantic port. The general offices of the Lehigh Valley Railroad are in the city. The Baltimore and Ohio enters where Chestnut Street crosses the Schuylkill. The tracks of the Pennsylvania are nearly all elevated or below grade, the Baltimore and Ohio below, and the Reading partly above, partly below, but mainly at grade. The Delaware River admits of the entrance of ocean vessels, and is navigable the entire length of the city's frontage, 18 miles. Work is now in progress to deepen the river to 30 feet. The Schuylkill River is navigable eight miles for vessels of light draught and is being dredged to a depth of 22 feet. The general export and import interests, including the Port Richmond coal wharves, are located mainly on the Delaware. Eleven transatlantic lines enter the port.

Early in the nineteenth century Philadelphia was first among United States ports in foreign commerce, but its relative importance declined, until in 1901 it ranked fourth. The imports for that year were valued at \$48,043,443, and the exports at \$79,354,025. In 1901, 158 sailing vessels, with an aggregate of 115,779 tons, and 950 steam vessels, of 1,807,623 tons, entered the port. The pipe lines of the Standard Oil Company from the wells in the northwest section of the State terminate at Point Breeze, on the Schuylkill, and oil is one of the largest and most valuable shipments of the port. In 1901 the exports of illuminating mineral oil amounted to 207,111,311 gallons, valued at \$12,323,961. The exports of corn for the same year amounted to \$12,633,467, one-seventh of the total for the country. Wheat and flour are also exported extensively. In 1901, 37,833 head of cattle were shipped, and there were also considerable exports of meat and meat products. Coal and copper are other important exports. The largest import is sugar, amounting in 1901 to a value of over \$15,500,000. Imports of unmanufactured silk were valued at over \$8,000,000. Among other leading imports are goat skins, fabrics, bananas, etc.

Philadelphia is a great manufacturing centre, ranking third in the United States in value of products. Of 15 selected industries in the census year 1900, it was first in one (leather), second in two (cigars and cigarettes, and women's factory clothing), and third in six. The value of the total output was \$732,137,957. This was nearly double the corresponding figure for 1880, but the greater part of the increase was made in the decade 1880-90. The manufacture of foundry and machine shop products is most important, amounting in 1900 to \$38,372,971. In this industry Philadel-

phia has a special advantage, owing to its proximity to abundant resources of coal and iron. It is noted particularly for the manufacture of locomotives, the Baldwin Locomotive Works, on North Broad Street, having a yearly capacity of 1500. For years Philadelphia has been the foremost shipbuilding centre in the country. Many warships of the United States and also a number for foreign governments have been built at the Cramp shipyard, which occupies some 52 acres in the Port Richmond section. These two establishments are not only the leading ones of Philadelphia, but each excels, in its own line, for the country at large. In the total manufacture of textiles also the city ranks first (though not for any one branch), the value of the principal textiles produced in 1900 being as follows: Woolen goods, \$18,340,012; worsted goods, \$16,242,250; cotton goods, \$15,723,654; hosiery and knit goods, \$13,040,905; silk and silk goods, \$4,531,794. The output of the sugar and molasses refining industry was valued at over \$36,000,000; the output of clothing, \$28,000,000; of carpets and rugs, nearly \$22,000,000; of leather, nearly \$20,000,000; and of liquors, over \$12,000,000.

GOVERNMENT. The executive branch of the government is of a dual nature, consisting of county and municipal departments. The municipal form of government is provided for by the Bullitt Bill, act of June 1, 1885, amended April, 1903, the basic elements of which are concentration of authority in the mayor and the distinction between the executive and legislative functions. The executive departments are: Public Safety, which includes bureaus of police, fire, electricity, corrections, boiler inspection, building inspection, and city property; Public Works, which includes bureaus of water, highways, gas, lighting, street cleaning, surveys, ice boats, and filtration (temporary); Law, Education, Public Health and Charities, Receiver of Taxes, City Comptroller, and City Treasurer (exofficio County Treasurer), and Supplies. The mayor, who is elected every four years and is ineligible for succession, appoints directors of the Departments of Public Works, Safety, Health, and Supplies, subject to confirmation by Select Council. Directors appoint chiefs of bureaus and other employees under civil service requirements. The receiver of taxes, city treasurer, city comptroller, and city solicitor are elected by popular suffrage. The Department of Education consists of 42 comptrollers, appointed by the judges of the Courts of Common Pleas. The Sinking Fund Commission consists of the mayor, city comptroller, and one member elected by Councils. The commissioners of Fairmount Park and members of the Board of Revision of Taxes, and the Board of City Trusts, in charge of Girard College and Estate and minor trusts, are also appointed by the courts. Sixteen port wardens are elected by the Councils. The county officials are commissioners in charge of elections, etc., treasurer, recorder of deeds, register of wills, clerk of the Court of Quarter Sessions, coroner, sheriff, and district attorney. The legislative function is exercised by Select and Common Councils, the former consisting of one member from each of 42 wards, the latter of one member for every 4000 voters. Select Councilmen serve three years, and Common Councilmen, two, without pay. The veto power is vested in the mayor, a three-fifths vote enacting over it. The judiciary consists of police magis-

trates (limited civil and preliminary criminal actions); judges of the Courts of Common Pleas (civil), who are also judges of the Courts of Quarter Sessions (criminal); and the judges of the Orphans' Court (estates). The Superior and Supreme Courts of Pennsylvania and the United States District and United States Circuit Courts sit in the city.

The city has leased its gas-works for a maximum period of 30 years, expiring December 31, 1927. Electric lighting is supplied by a private corporation. The water-works are under municipal ownership. A system of slow sand filtration is being installed, and in August, 1903, when upward of \$17,000,000 was involved in contracts, it was over half finished and in partial operation. The complete works, with a daily capacity of 300,000,000 gallons, are estimated to cost \$26,000,000.

FINANCES. The city's receipts for 1902 were \$33,520,729. The important items were: taxes, \$16,793,680; gas, \$486,491; State appropriation (1901-02) for schools and teachers' annuities, \$316,000; loans negotiated, \$6,915,000; personal property tax, \$1,249,332; permits, fees, etc., \$7,400,000, including water rents, \$3,422,000, liquor licenses, \$1,766,000, and premiums on loans, \$581,000; interest, \$365,000. The expenditures were \$34,605,948; the largest item was \$25,904,693 for municipal departments and bureaus; of this amount schools received \$4,186,000; police, \$3,565,000; fire, \$1,124,000; water, \$6,511,000; highways, \$2,109,000; street cleaning, \$1,238,000. Other large disbursements were: interest on funded debt, \$1,404,036; several sinking funds, \$1,727,787; loans redeemed, \$680,000; mandamuses, \$1,456,105. The general cash balance on January 1, 1903, was \$17,166,865. The gross debt at the same date was \$59,361,845; the city loans held by the sinking fund amounted to \$6,645,300, leaving a net city debt of \$52,716,545; the total assets were \$29,132,473, not including the real estate owned by the city, valued at \$64,520,994. The assessed real estate valuation, as estimated in August, 1903, for 1904, was \$1,160,392,710. Under the law the debt is limited to 7 per cent. All permanent loans after the 2 per cent. point has been exceeded must be authorized by a vote of the people.

POPULATION. The population in 1900 was 1,293,697, Philadelphia ranking third among American cities. Since 1854 no territory has been added to the municipal limits. The percentage of increase from 1880 to 1890 was 23.58, and from 1890 to 1900, 23.57. Fifty-four and seven-tenths per cent. of the white population is of foreign parentage, but native whites of foreign birth comprise 32 per cent. of the entire population. The negroes numbered 28,940 in 1900; Chinese, Japanese, and Indians, 1277. The largest classes of European descent are German, Irish, English, and Italian. French, Greeks, Armenians, Russians, Bohemians, and Poles are present in much lesser numbers. Though some tendency to congregate is shown, there are few well-defined foreign colonies. In 1800 the population of Philadelphia was 28,522; in 1820, 63,802; in 1840, 93,665; in 1860, 563,529; in 1880, 847,170; in 1890, 1,046,964.

HISTORY. The first settlement (called Wicaco) within the present limits of Philadelphia was made in 1636 by a company of Swedes sent out by the Government of Queen Chris-

tina. On October 7, 1681, Captain William Markham, Deputy Governor for William Penn, arrived with a small company, and started an English settlement here, which in July of the following year was laid out and called Philadelphia, 'the city of brotherly love.' In 1683 a company of Germans, invited hither by Penn, arrived and settled at Germantown, within the present city limits. In 1684, immigration having been rapid from the start, there were 300 houses and more than 2500 inhabitants. The majority of the early settlers were Friends, and their influence, combined with that of the Germans, predominated for many years and greatly affected the course of Pennsylvania's history. Penn returned to England in 1684, and did not revisit the city until 1699, when he found a population of 4500, and 700 houses. He chartered the city in 1701, and thereafter frequent controversies arose between the people and the Penn family over proprietary privileges, especially as regards taxation of the Penn lands. The first English school was opened in 1683. Franklin's *Pennsylvania Gazette* began publication in 1729 and the *Pennsylvania Journal and Weekly Advertiser* was started in 1742. In 1741 the city, then having 1621 taxable citizens, was divided into ten wards. In 1723 Benjamin Franklin, who, next to Penn, exerted the greatest influence in the history of the city, came to Philadelphia. In 1747, during King George's war with the French and Indians, the publication of his *Plain Truth* roused a spirit of military enthusiasm, a force of 10,000 was raised in Pennsylvania, and a battery was erected below the city, on the site of the present United States Navy Yard. In 1751 the first line of packets to New York was established, followed in 1756 by a stage line. Under Franklin's influence, in 1747 the merchants of Philadelphia sent a ship to discover the Northwest Passage. In 1755 a militia bill was passed, and Franklin became colonel of the city regiment.

From 1763 to 1774 Philadelphia was prominent in resisting British aggression, though the Loyalist party was strong, and most of the Friends opposed warfare; and here most of the important official events of the Revolution took place. In 1773 (October 17), during the excitement over the expected arrival of the tea ships, the people met in mass meeting and passed resolutions which, on November 5th, were readopted at Boston. The first Continental Congress met in Carpenter's Hall, September 5, 1774; the second met May 10, 1775, in the State House; and there, on June 15th, Washington was appointed commander-in-chief of the Continental army. In 1776 Congress met for the third time in the State House, and there, on July 4th, the Declaration of Independence was adopted. Philadelphia was held by the British from September 27, 1777, to June 18, 1778, and during this period, while the American army was at Valley Forge, was the scene of much gayety. On May 18, 1778, the famous entertainment called the *Mischianza* (q.v.), was given in honor of General Howe, who was about to depart for Europe. On October 4, 1777, the battle of Germantown (q.v.) was fought. On May 2, 1787, delegates from the different States assembled here, and, after almost four months of debate behind closed doors, adopted a Constitution for the United States, September 17th. On March 11, 1789, the city received a new charter from the Legislature. Epidemics of

yellow fever in 1793 and 1798 caused great loss of life, at least 4000 dying in the former year and almost 5000 out of the 30,000 who remained in the city in the latter.

During the latter part of the eighteenth century and the early part of the nineteenth Philadelphia was the most important city in America. The historian McMaster says of it in 1784: "The city was then the greatest in the country. No other could boast of so many streets, so many houses, so many people, so much renown;" and Liancourt describes it in 1800 as "not only the finest city in the United States, but . . . one of the most beautiful cities of the world." Philadelphia was the capital of Pennsylvania from 1683 until 1799, the seat of the Federal Government from 1790 to 1800, and the monetary centre of the country until 1836. (See BANK, BANKING.) For many years, also, it was the intellectual and literary centre of the country. Here were published the first newspaper in the middle colonies, *American Weekly Mercury* (1719); the first secular magazine in North America, *Ein geistliches Magazin* (1764); the first daily newspaper in the United States, the *Pennsylvania Packet* (1784); the first American edition of the Bible in German (1743), and in English (1781), and the first religious weekly, *Religious Remembrancer* (1813). The most popular of the early American magazines—the *Port Folio* and the *Analectic*—were also published here.

Philadelphia took the lead in the early anti-slavery movement, the first formal protest against slavery in this country being made by four Germans of Germantown in 1688, the first Abolition convention being held here January 1, 1794, on the invitation of the Pennsylvania Abolition Society, and the American Anti-Slavery Society being founded here, until the leadership of Garrison, in 1833. In 1812 the water-works at Fairmount were begun and were finished in 1815. In 1832 nearly 1000 deaths resulted from Asiatic cholera. In May, 1838, an anti-Abolitionist mob destroyed Pennsylvania Hall, in which an Abolitionist meeting had been just held. In 1844 occurred the anti-Catholic riots, arising from the demand of the Catholics to be permitted to use the Douai instead of the King James Bible in the public schools. The anti-Catholics, or 'Native Americans,' burned Saint Michael's and Saint Augustine's churches, and caused much loss of life before they were put down by the militia. Gas was introduced in 1836, and the first telegraph line was established in April, 1846. On February 2, 1854, a consolidation act was passed by the Legislature, extending the city limits to the county boundaries, and uniting under one municipal government all the outlying districts, known as Southwark, Northern Liberties, Kensington, Spring Garden, Moyamensing, Penn. Richmond, West Philadelphia, and Belmont; also the boroughs of Germantown, Manayunk, and other townships. Philadelphia took an active part in the Civil War, and raised more than \$1,000,000 by a sanitary fair in 1864. The centenary of American independence was celebrated in 1876 by the Centennial Exposition; the bi-centennial of the landing of William Penn in 1882; and the centennial of the signing of the Constitution in 1887.

cott, *History of Philadelphia, 1609-1884* (ib., 1884); Allinson and Penrose, *Philadelphia, 1684-1887* (ib., 1887); Trades League, *The Book of Philadelphia, 1894* (ib., 1894); Repplier, *Philadelphia, the Place and the People* (New York, 1895); Young, *Memorial History* (ib., 1895); Fisher, *The Making of Pennsylvania* (Philadelphia, 1896); id., *Chapters in Pennsylvania, Colony and Commonwealth* (ib., 1897); Rhoades, *The Story of Philadelphia* (New York, 1900); King, *Philadelphia and Notable Philadelphians* (ib., 1902).

PHILADELPHIA ACADEMY OF NATURAL SCIENCES. An association founded in 1812 for the purpose of furthering the study of the natural sciences and encouraging original investigation in the various fields of physical research. It is the oldest organization in the United States devoted to the encouragement of natural science. Its museum is especially rich in ornithological specimens and fossils, while its collection of shells is the finest in the world. The Jessup foundation provides gratuitous training for a number of young investigators. The society has published a *Journal* since 1817 and its *Proceedings* since 1841.

PHILADELPH'US (Neo-Lat., from Gk. *φιλᾶδελφος*, *philadelphos*, sort of flowering shrub, perhaps jasmine; named in honor of Ptolemy Philadelphus, King of Egypt). A genus of shrubs of the natural order Saxifragaceæ. Several species are natives of the southern Atlantic and Pacific States and Japan. *Philadelphus inodorus* grows in the mountains from Virginia southward. *Philadelphus grandiflorus* grows in lower ground in the same region. *Philadelphus hirsutus* grows in Tennessee and North Carolina. *Philadelphus Gordonianus* and *Philadelphus Lewisii* are natives of the Pacific Coast States. The most common and best representative of the genus, however, is *Philadelphus coronarius*, the common mock orange or syringa, much cultivated in gardens. Its native country is not known, but it was probably brought from Japan to Southern Europe, where it appears to be indigenous. It has erect branches, oblong ovate leaves, which when crushed have very much the odor and taste of cucumbers. Its cream-colored flowers, borne in large clusters, are well known for their exceeding fragrance.

PHILÆ (Lat., from Gk. *φιλᾶ*, Coptic *Pilâ-kêh*, the corner, extremity, i.e. of Egypt). A celebrated island in the Nile, just above the First Cataract, in latitude 24° 1' N. It is a small granite rock, about 1000 feet long by 500 feet broad, and is covered with ancient buildings of great architectural value and interest. By the Arabs it is called *Geziret Anas el-Wogûd*, 'The island of Anas el-Wogûd,' from the name of the hero of a tale in the *Thousand and One Nights*, the scene of which is laid here. Philæ is not mentioned in the Egyptian inscriptions before the time of Nectanebo II., who constructed the oldest of the buildings that now remain, though it is reasonably certain that a temple existed there in earlier times. The island was especially devoted to the worship of the goddess Isis, but Osiris, Hathor, Khnum, Satet, and other divinities were also worshiped there. In later times, when the cult of Isis had spread through the Greek and Roman world, many pilgrims of foreign nationality visited the shrine of the goddess at Philæ, and her

worship was maintained there long after heathenism had been banished from other parts of Egypt. The great temple of Isis was built by Ptolemy Philadelphus and his successor, Euergetes I., but additions and embellishments were made by other Ptolemies and by several of the Roman emperors. The approach to the temple is formed by the dromos, a long open space, flanked on its eastern and western sides by colonnaded walks. At the southern end is the hall of Nectanebo II., built about n.c. 350, and near it to the right is the ruined temple of the Nubian deity Arnuphis (Ar-hes-nofer). Starting from this temple, the eastern colonnade runs northward to the small temple of Imhotep (Asklepios), and terminates near a gate built by Ptolemy Philadelphus and adorned with reliefs by that monarch and by the Emperor Tiberius. The western colonnade is pierced by a number of windows which give a fine view over the river. It runs along a fine stone quay of ancient construction. At the northern end of the dromos stands the great pylon of Nectanebo II., leading into the outer court, on the eastern side of which are a number of chambers, built for the use of the priests, while on the western side is the birth-house, commemorating the birth of Horus. Among the reliefs and inscriptions upon the walls of the latter building is a copy in hieroglyphic and demotic of the text of the Rosetta stone (q.v.). At the upper end of the outer court is a second pylon, which gives entrance to the inner court leading to a columned hall, and from this, through a succession of smaller halls and chambers, lies the way to the sanctuary of the goddess Isis and her son Harpocrates (q.v.). In an upper story is a room decorated with scenes from the myth of Osiris (q.v.). The temple is decorated throughout with sculptures and reliefs which are well preserved and are richly colored. West of the temple of Isis, near the river, are a gate built by the Emperor Hadrian and the temple of Harendotes (Egyptian *Har-nez-yotf*, 'Horus the avenger of his father'). On the eastern side of the island is the small temple of Hathor built by Ptolemy Philometor and Euergetes II., and near it, close to the river bank, is a beautiful pavilion resting upon light and graceful columns and richly adorned with reliefs. On the northern end of the island, among the ruins of the ancient city of Philæ, are the remains of the old Roman city gate, of the temple of Augustus, and of a Coptic church. It was expected (1903) that the great dam at Assuan would so raise the level of the Nile at Philæ as to submerge the island. See Plate accompanying article EGYPTIAN ART.

PHILANDER. A Dutch knight in Ariosto's *Orlando Furioso*, who made love to Gabrina, the wife of his host. His name is used as the synonym of a male coquette in various plays, and is the origin of the verb to philander.

PHILANTHROPY (Lat. *philanthropia*, from Gk. *φιλανθρωπία*, love of humanity, from *φίλανθρωλος*).

πῶς, *philanthropos*, loving humanity, from *φιλεῖν*, *philein*, to love + *ἄνθρωπος*, *anthrōpos*, man). In German educational history, a term applied to the theories of a group of men who based their educational theories upon Rousseau. At the head of these was Basedow, who founded an institution, the Philanthropinum, at Dessau in 1774. The only survival of the movement is Salzmann's institution at Schnepfenthal in Gotha, founded in 1784. See BASEDOW.

PHILARET, *ἱεὶλά-ρέτ* (VASILI FEODOROVITCH DROSDOFF) (1783-1867). Metropolitan of Moscow. He was born at Kolonna; became a priest in 1808 and in 1812 was made rector of the Theological Academy of Saint Petersburg. In 1817 he became Bishop of Revel, in 1819 Archbishop of Tver and a member of the Holy Synod. In 1820 he was transferred to Yaroslav and in 1821 to Moscow. He was appointed Metropolitan of Moscow in 1825. He was noted for learning and eloquence, and drew up the manifesto which led to the abolition of serfdom. He prepared a longer and a shorter catechism, both of which were adopted and promulgated by the Holy Synod in 1839, and the former is considered the most authoritative doctrinal standard of the Græco-Russian Church. Both catechisms have been translated into English by Blackmore in *The Doctrine of the Russian Church* (London, 1845); Blackmore's translation of the longer catechism is reprinted in Schaff, *The Creeds of Christendom*, vol. ii., pp. 445-542. There has also been published a volume of Philaret's *Select Sermons* in English translation (London, 1873), with brief biography. He began a translation of the New Testament into Russian, which was completed after his death.

PHILASTER, OR, LOVE LIES A-BLEEDING. A tragedy by Beaumont with some assistance from Fletcher. G. C. Macauley considers it the work of Beaumont alone. It was printed probably in 1608, and printed in 1620. Several versions were produced, one as late as 1764.

PHILATELIC ASSOCIATION (from Gk. *φίλος*, *philos*, loving, from *φιλεῖν*, *philein*, to love + *ἀτέλης*, *ateles*, free of tax, prepaid, from *α-*, not + *τέλος*, *telos*, tax, duty), AMERICAN. A national society of postage stamp collectors, founded in 1885, meeting annually in such cities as may be selected, and having local branch societies in New York, Chicago, Pittsburg, and Saint Paul. It has a membership of nearly six hundred, and its objects are to bring together those interested in philately, and to study that subject with the help of exhibitions of collections.

PHILATELIC SOCIETY OF LONDON. An English association of collectors of postage stamps, founded in London in 1869, the first of its kind. Its objects are the study of postage stamps, their history and manufacture, the detection of forgeries, the exhibition of stamps, and the publication of works on these subjects. The membership includes many collectors in the English colonies and on the Continent. The society has conducted two international philatelic exhibitions. It has also published expensive volumes on the stamps of great Britain, of the British colonies, of India and Ceylon, and of Africa, and issues its proceedings in the *Monthly Journal*.

PHILATELY. See POSTAGE STAMPS.

PHILBRICK, JOHN DUDLEY (1818-86). An American educator, born in Deerfield, N. H. He graduated at Dartmouth in 1842 and afterwards taught in Boston for ten years. In 1853 he became principal of the Connecticut Normal School, and in 1855 superintendent of schools in that State. From 1857 to 1874 and again from 1876 to 1878 he was superintendent of the Boston public schools. He was sent to the Vienna Exposition of 1873 as educational commissioner from Massachusetts, and acted as a member of the international jury. After his return he became president of the National Teachers' Association and was officer of many educational societies. He prepared a valuable report on the *City School Systems in the United States* (published by the United States Bureau of Education in 1885) and edited the Connecticut *Common School Journal*, and the *Massachusetts Teacher*.

PHILELPHUS. The Latinized form of the name of the Italian humanist Francesco Filelfo (q.v.).

PHILEMON (Lat., from Gk. *Φιλήμων*) (c.361-263 B.C.). A Greek comic poet. He was a native of Soli, in Cilicia, or of Syracuse, in Sicily. He resided chiefly in Athens, but for a time also in Alexandria at the Court of Ptolemy Philadelphus. He and Menander were the two representative poets of the Attic New Comedy. Philemon gained more prizes than Menander, perhaps through bribery of the judges. Posterity, however, reversed the decision, and Menander and Homer were the two favorite poets of later Greece. Of the 97 comedies which Philemon left, 57 are known to us from titles and fragments, while two at least, the *Εμπορος* and *Θησαυρός*, are preserved in Plautus's adaptations, the *Mercator* and *Trinummus*; and it is also probable that Plautus's *Mostellaria* follows Philemon's *Φόσμα*. The fragments are published by Koch, *Comicorum Atticorum Fragmenta*, vol. ii. (Leipzig, 1886).

PHILEMON. A dear friend of the Apostle Paul, to whom he wrote the letter which is now preserved in the New Testament under Philemon's name. From this letter it appears that he was a rich man who probably lived at Colossæ, owned slaves, was noted for his hospitality, and had become a Christian under Paul's influence. There are legendary accounts of Philemon's later accession to the Bishopric of Colossæ and of his martyrdom there under the Emperor Nero.

PHILEMON, EPISTLE TO. One of the Epistles of the New Testament and the only letter of Paul written to an individual on a purely private matter which has been preserved. In it Paul appeals to his friend Philemon in behalf of Onesimus, a fugitive slave, who, under the influence of Paul, had become a convert to the Christian faith. This fugitive Paul sends back to his master with a letter praying for the culprit's pardon and even hinting at emancipation. The letter was, almost without doubt, written from Rome, some time after Paul's arrival there in the spring of A.D. 59. The most significant value of the letter is its bearing upon the question of human slavery. The practice is not condemned, but the new doctrine of the brotherhood of man is emphasized as in the Colossian and Ephesian letters, written at the same time. Consult: Eliott, *Philippians, Colossians, and Philemon* (Andover, 1865); Lightfoot, *Colossians and Philemon*

(1876); Soden in *Hand-Commentar zum Neuen Testament*, vol. iii. (Freiburg, 1893); Moule, *Colossians and Philemon* (*Cambridge Bible for Schools and Colleges*, Cambridge, 1894); Vincent, *Philippians and Philemon* (*International Critical Commentary*, New York, 1897); Maclaren, *Colossians and Philemon* (*Expositor's Bible*, New York, 1903).

PHILEMON AND BAUCIS. According to a myth related by Ovid in his *Metamorphoses*, a pair of poor Phrygian peasants, Jupiter and Mercury, wandering through Phrygia in human form, were hospitably entertained by them, when all the neighborhood had turned the wanderers from their doors. On going away the gods took them with them to a neighboring mountain, whence they saw their village covered with a flood, but their own cottage changed into a splendid temple. Jupiter permitted them to make any request they chose, but they only asked to be servants of his temple and to die at the same time. Therefore in their extreme old age the gods transformed Philemon into an oak, Baucis into a linden, which long stood in front of the temple, and were honored by the people. The story, which has been much elaborated by Ovid, contains two elements common in popular tales: the rescue from a flood by divine interposition and the reward for hospitality to supernatural visitors in disguise. The vitality of the legend in Phrygia seems emphasized by the experience of Paul and Barnabas at Lystra (Acts xiv.).

PHILETAS (Lat., from Gk. Φιλάτας) OF COS. A Greek grammarian and poet who lived about the close of the fourth century B.C., tutor to Ptolemy II. Philadelphus of Alexandria. His poems, which were chiefly elegies devoted to the praises of his mistress, Bannis, were ranked next to those of Callimachus by the Alexandrian critics, and were imitated by Propertius. He wrote also epics and grammatical treatises. The scanty fragments that remain have been published by Bach (1829). Consult Weber, *Elegischen Dichtern des Hellenen* (Frankfurt, 1826).

PHILHARMONIC SOCIETIES (from Gk. φιλεῖν, *philein*, to love + ἁρμονία, *harmonia*, harmony). Organizations formed for the cultivation of orchestral music. The four most important are those of London, New York, Vienna, and Berlin.

LONDON. This is the oldest association of orchestral performers in England. In 1813 a number of music-lovers founded the Philharmonic Society and the first concert was given March 8th of that year. According to the constitution only concerted pieces were to be performed; all soli and concertos were excluded. But when a little later some of the members formed quartets the society ceased to perform chamber-music at its concerts and restricted itself to instrumental works for orchestra. In 1820 the term *conductor* (q.v.) appears for the first time upon the programmes, and it designated the person at the piano. After 1821 the conductor stood before the orchestra and directed by means of a baton. Since 1869 the organization has published analytical programmes for its concerts, at which the most eminent instrumental and vocal artists of their time have appeared.

NEW YORK. The Philharmonic is the oldest per-

manent orchestral association in New York. It was founded in 1842, the first concert taking place December 7th of that year. From the beginning it consisted of professional musicians only. As an educational factor the Philharmonic Society has been of greater importance in the musical life of America than any other organization, with the possible exception of the Boston Handel and Haydn Society. (See **CHORAL SOCIETIES**.) Up to 1865 various members of the orchestra acted as conductors. Beginning with that year a conductor for the season was chosen, the first being Carl Bergmann, who directed the concerts until 1876. After Dr. Damrosch had been conductor for one season, Theodore Thomas held the post from 1877 to 1890. This eminent director was succeeded by Anton Seidl. From 1898 to 1902 Emil Paur was conductor, and this period was marked by the production of an unusual number of new works, especially of the Neo-German school. In 1902 Walter Damrosch was conductor. The orchestra numbers over one hundred performers. Eight concerts take place on Saturday nights, each being preceded on Friday afternoons by a public rehearsal, which, in reality, is a regular concert, having its own list of subscribers.

VIENNA. The society, known as *Philharmonische Gesellschaft*, was founded in 1842 by Otto Nicolai, at that time conductor at the Imperial Opera. As the *Gesellschaft der Musikfreunde* (q.v.) was fast degenerating, there was a positive need of an organization that would give artistic performances. The first concert of the new society took place November 27, 1842, and the venture immediately met with great favor and financial success. The programmes consisted generally of two symphonies with smaller works. Instrumental solos, however, were not permitted. When Nicolai accepted a position in Berlin in 1847 the *Philharmonische Gesellschaft* almost came to an end. In fact, no concerts were given from 1850 to 1854. Then Carl Eekert reorganized the orchestra, and in 1860 the energetic Otto Dessoff succeeded in bringing the orchestra to a high degree of perfection. Since then the *Philharmonische Concerte* have stood always for musical progress. The conductor in 1902 was Hans Richter, under whose leadership the society has established its reputation as one of the foremost orchestral institutions of the world.

BERLIN. The Berlin Philharmonic Society was founded by Edward Rietz (1802-32). This orchestra at first consisted of about forty instruments, but the number was subsequently increased and the organization now ranks with the best orchestras of Europe. Its concerts are given in the 'Philharmonie.' An innovation is its series of popular concerts given three times a week during the winter.

PHILHELLENES, fil-hél'lénz (from Gk. φιλέλλην, *philhellén*, friend of the Greeks, from φιλεῖν, *philein*, to love + Ἑλλήν, *Hellén*, Greek). A name given to the friends of the Greeks in their struggle for independence. They were constituted into associations for the purpose of receiving and distributing gifts in aid of those engaged in the contest. The members came from all countries, including such men as Byron, King Louis I. of Bavaria, and a body of volunteers who fought for the Greeks under the leadership of General Normann-Ehrenfels.

PHILIDOR (1726-95). A famous French chess-player also known as a composer. His real name was François André Danican.

PHILINTE, *félicité*. A character in Molière's *Misanthrope*, whose easy tolerance of the shortcomings of his fellows sets him in strong contrast to his friend Alceste.

PHILIP (Lat. *Philippus*, from Gk. *Φίλιππος*, Philip, loving horses, from *φίλειν*, *philein*, to love + *ἵππος*, *hippos*, horse), **THE APOSTLE**. One of the more prominent of the twelve disciples of Jesus. He was a fellow-townsmen of Andrew and Peter and had been with them a follower of John the Baptist before he was called directly to become a disciple of Christ (John i. 43-44). When the company of the Twelve was definitely made up Philip became evidently one of their leading spirits, for his name stands in the lists at the head of the second of the three groups of four into which the Twelve are commonly divided. He does not figure extensively, however, in the records of the ministry of Jesus. His work after the death of Christ is involved in great confusion with that of Philip the Evangelist by the traditions. There are two apocryphal works bearing his name, the *Journeyings of Philip the Apostle* and the *Acts of Philip*. They are of slight historical value, however. Tradition of the safer sort assigns his labors to the region of Hierapolis in Asia Minor. The manner of his death and its date are both unknown.

PHILIP, THE EVANGELIST. One of those chosen by the first Christian church in Jerusalem to be the stewards of its charity to the widows and poor (Acts vi. 5). After exercising this office for a time he was engaged in missionary activity, which began after the death of Stephen. His initial work was among the Samaritans (Acts viii. 4-5). This was the first step outward from the limits of a Jewish cult for the new Christian faith. A second step in the process of widening the field was taken when Philip gave baptism to an Ethiopian eunuch (Acts viii. 26-40). Philip finally settled in the region of Cæsarea, on the coast of the Mediterranean, where he was found by Paul, who was entertained at his house (Acts xxi. 8). Tradition is not clear concerning his life after this, although there is pretty general agreement that he died a natural death at Tralles.

PHILIP II. (B.C. 382-336). King of Macedonia and father of Alexander the Great. He was born at Pella and was the youngest son of Amyntas II. and Eurydice. When a youth he was taken by Pelopidas as a hostage to Thebes, where he lived several years. After the murder of his eldest brother, Alexander, by Ptolemy Alorites, he was appointed by his brother Perdiccas, when the latter, having slain Ptolemy, came to the throne, to the governorship of a separate district of the country. About B.C. 359 Perdiccas was slain in battle, while fighting with the Illyrians, and Philip assumed the government as guardian of his young nephew, Amyntas, the son of Perdiccas; but he soon set aside Amyntas and took the crown himself. At this time Macedonia was attacked on one side by the Illyrians, Pannonians, and other tribes, and on the other by the Athenians, while within she was torn by the dissensions of several pretenders to the throne; but, buying off the Thracians, who were supporting the pretender Pau-

sanias; conciliating the Athenians, who had taken up the cause of another pretender, Argæus; killing or otherwise disposing of the remaining pretenders, and defeating in battle the threatening tribes, Philip in less than two years firmly established himself on his throne. Henceforward his policy was one of aggression, and the Greek towns on the coast of Macedonia were the first objects of attack. Amphipolis, Pydna, and Potidæa, Athenian possessions or allies on the coast of Macedonia, were the earliest places to fall into his hands. He then secured possession of the rich and valuable gold mines of Thrace, together with the town of Crenides, which he enlarged and called by the name of Philippi. These victories had all been obtained before 355; in 354 he took Methone, on the Thermaic Gulf, after a long siege, in the course of which he lost an eye, and then advanced into Thessaly, to aid the Aleuadæ against Lycophron, the tyrant of Phæræ. Defeating the force that was sent to oppose him, he established his supremacy throughout Thessaly and advanced as far south as the pass of Thermopylæ. The pass being guarded by a strong force of Athenians, who had been aroused by the eloquent warnings of Demosthenes, he returned and directed his arms against Thrace, where he succeeded in establishing his ascendancy. In 349 he began his attacks on the Chalcidian cities, and in 347 completed the conquest of the Chalcidic peninsula by taking the city of Olynthus. In 346 he succeeded in gaining a further foothold in Greece, being called in by the Thebans to assist in the Sacred War against the Phocians. All the towns of Phocis, twenty-two in number, together with the pass of Thermopylæ, surrendered to Philip without resistance. The place which the Phocians had occupied in the Amphictyonic Council was transferred to him, and he was appointed, jointly with the Thebians and Thessalians, president of the Pythian games. In the following years he was again in Thrace, endeavoring to bring the cities in that country under his rule. He was unsuccessful in his attempt on Perinthus and Byzantium, and then turned his attention once more to the northern tribes. In B.C. 339 he was again invited into Greece, this time by the Amphictyonic Council, to take charge of the army that was to oppose the Locrians. Alarmed at his continued successes and his entrance into Greece, the Athenians formed a coalition with Thebes and other Greek States to oppose his advance, but the united army was utterly defeated at the battle of Chæronea in 338. This battle marks the end of Greek independence; Philip was now master of Greece. He at once began preparations for the invasion of Persia on a grand scale, and in 377, deputies from all the different States of Greece except Sparta assembling at Corinth, he was chosen commander-in-chief of the Greek forces. In the midst of his preparations, however, he was assassinated at Egæ by a youth of noble blood named Pausanias, while attending a celebration in honor of the marriage of his daughter with Alexander of Epirus (B.C. 336). The motive for the deed, as stated by Aristotle, was private resentment for neglect on Philip's part to punish Attalus for a gross insult offered to Pausanias.

PHILIP III. A king of Macedonia. See **ARRHIDEUS**.

PHILIP V. (n.c. 237-179). King of Macedonia, son of Demetrius II. and grandson of Antigonus Gonatas. He succeeded his uncle Antigonus Doston in 220. The first part of his reign was disturbed by the contentions of the Ætolian and Achaean Leagues; taking part with the latter, he conducted the war for several campaigns with ability and success. This war was called the Social War, and was concluded in 217, by the Peace of Naupactus. In 216-215 Philip was induced by the successes of Hannibal in Italy to conclude an offensive and defensive alliance with Carthage, the price of which was to be the Roman possessions in Hlyria and the help of Carthage in his Grecian wars. The war which followed (214-205) is known as the First Macedonian War; at no time in the course of it did Philip render Hannibal any effective aid, and for the first three years the war was conducted on both sides with lack of energy. In 214 the Roman general, M. Valerius Leuinus, compelled Philip to raise the siege of Apollonia, and in 211 Rome organized against Macedon a coalition of Greek States with the Ætolian League at the head. Peace was concluded in 205 without material gain on either side. In 204 Philip made a bargain with Antiochus III. to divide between them certain of the dominions of the youthful King of Egypt, Ptolemy Epiphanes. This interference of Philip in the East precipitated the Second Macedonian War with Rome, which began in 200 and was brought to a close by the battle of Cynoscephale in 197. In this battle the Macedonian army was utterly defeated by Titus Quintius Flaminius; Philip was compelled to relinquish his conquests in Europe and Asia, to surrender his fleet, and to pay an indemnity of a thousand talents; Macedonia became an ally, subject to the control of Rome. Philip died in 179, and was succeeded by his son Perseus. Consult: Draysen, *Geschichte des Hellenismus* (2d ed., Gotha, 1877-78); Freeman, *History of Federal Government* (2d ed., New York, 1893); Mahaffy, *Alexander's Empire* (New York, 1888).

PHILIP I. (c.1052-1108). King of France from 1060 to 1108. He was the eldest son of King Henry I. and Anne of Russia. Until 1066, when Philip came of age, his mother and his uncle, Baldwin V. of Flanders, were regents. In the various contests of his great feudatories, to whom belonged William I. of England as Duke of Normandy, Philip often intervened successfully, so that the royal domain was increased until it extended from the valley of the Seine to the valley of the Loire, and also included Bourges. About 1071 Philip married Bertha, step-daughter of Count Robert of Holland. Though a son was born to them in 1081 (later Louis VI.), and afterwards a daughter, Philip nevertheless repudiated his wife in 1092, and began to live with Bertrada, the wife of Count Fulk of Anjou. The result was a continuous strife between the Papacy and the King. In 1095, at the Council of Clermont, Urban II. excommunicated Philip, though Bertha had died in 1094. This excommunication was raised after Philip had promised to put Bertrada away, but renewed in 1097, when he relapsed. In 1105, after Bertrada had died, he was released from the ban. Consult Luchaire, *Louis VI. le Gros* (Paris, 1890).

PHILIP II., or **PHILIP AUGUSTUS** (1165-1223). King of France from 1180 to 1223. He

was the son of Louis VII. and Adèle of Champagne, and was born on August 21, 1165. He was crowned on November 1, 1179, during the life of his father, succeeded him in 1108, and proved one of the greatest monarchs of the Capetian dynasty. In 1181 he made war upon the Count of Flanders and in 1185 forced him to surrender the districts of Vermandois and Amiénois. In 1182 he drove the Jews out of his territories and confiscated all their wealth. In 1187 the English attempt to conquer Languedoc caused a war, in which Philip was aided by the sons of Henry II. (q.v.). After the accession (1189) of Richard to the English throne, Philip and he set out together on the Third Crusade (1190), but quarreled while wintering in Sicily, and their dissensions continuing, Philip, after a sojourn of three and a half months in Syria, set out on his return to France, after taking a solemn oath to respect the integrity of Richard's dominions. No sooner, however, had he returned than he entered into an arrangement for the partition of Richard's territories in France with his unworthy brother, John. Some acquisitions were made, but Richard's return thwarted the calculations of the conspirators, and a war immediately commenced between the two monarchs, in which Philip had at one and the same time to defend his territories against the English and the counts of Champagne, Boulogne, Brittany, and Hainault, who attacked them on all sides. Richard died in 1199; but on the appeal of the Barons of Poitou to Philip, as John's overlord, the war soon recommenced against John (q.v.). The English provinces in France were attacked by the combined French and Bretons, and Normandy, Poitou, Maine, Anjou, and Touraine were annexed to France. In the years 1213 and 1214 Philip waged war against Flanders and thus caused a coalition to be formed by Otho IV. (q.v.) of Germany, John of England, and the Count of Flanders. Philip defeated the allies in 1214 at Bouvines (q.v.). During the rest of his reign Philip was occupied in consolidating his new possessions, and took no part in the war against the Albigenses. In general Philip was in alliance with the Church and the great cities. His first wife was Isabella of Hainault, the mother of Louis VIII.; he next married Ingeborg of Denmark, but repudiated her in 1196 to marry Agnes of Meran. For this he was excommunicated and France was placed under an interdict. Philip yielded in 1200 and took back Ingeborg. He improved and embellished Paris, built many churches and other institutions, encouraged commercial associations, and gave the first charter to the University of Paris. He fortified many of the chief towns, including the capital. He died at Mantes, July 14, 1223. Philip was the first monarch under whom France attained a commanding position in Europe. Consult: Cartellieri, *Philip II., August* (Leipzig, 1899); Luchaire, *Philippe Auguste* (Paris, 1881).

PHILIP III., **L'HARDI**, i.e. the Bold (1245-85). King of France from 1270 to 1285. He was the son of Louis IX., and had his father's piety, but not his ability. He was an unimportant man personally, but his reign is noted on account of the rise of the lawyers as a class of royal advisers. Consult Langlois, *Le règne de Philippe III. le Hardi* (Paris, 1887).

PHILIP IV., THE FAIR (1268-1314). King of France from 1285 to 1314. He succeeded his father, Philip III. During his reign, which was of exceeding importance for the development of the French monarchy, he had three prominent advisers, Pierre Flotte, William of Nogaret, and Enguerrand of Marigny, who, being all taken from the rising legal class, were known as *légistes*. The event which stands out most prominently in this reign was the conflict with the Papacy under Boniface VIII. (q.v.). The French government sought to tax the clergy, whereupon Boniface interfered and issued the bull *Clericis laicos* in 1296, ordering the clergy to refuse obedience to the King. Boniface, it is true, gave way at once when a decree was issued forbidding the exportation of metals from France, the effect of which would have been to cut off a large portion of the Papal revenue, but the success of the Jubilee at Rome in 1300 induced Boniface to believe that he would find sufficient support in a struggle with Philip IV., and hence when in 1301 Bernard Saisset, Bishop of Pamiers, a Papal representative in France, was arrested there, Boniface issued his famous bull *Unam sanctam*. This set forth the highest Papal pretensions, and was a challenge to all monarchs of Europe. Philip, in order to be certain of support, summoned for the first time in the history of France the States-General. In 1303 while Boniface was at Anagni he was suddenly captured by William of Nogaret, and, though released the following day, he died soon after as a result of the shock. After the short rule of Benedict XI., Philip obtained in 1305 the election of his adherent, the Archbishop of Bordeaux, to the Papal chair, as Clement V. In 1309 the Pope took up his residence at Avignon, and until 1378 the Papacy was entirely under French influence, this being the period of the so-called Babylonish Captivity. See PAPACY.

On account of the increased expenditures of the monarchy, due to its greater extension and enlarged duties, it was found more and more difficult to carry on the government with the old revenues alone. A temporary expedient was found by compelling Clement V. to condemn the wealthy Templars and deliver their property over to the French King. Philip early in his reign had difficulties with Edward I. of England. In 1294 he took possession of Guienne, Edward's territory, and in 1297 attacked Guy, Count of Flanders, who had supported the English monarch. Boniface VIII. brought about a truce in 1298, and Guienne was restored to Edward. When, however, Guy of Flanders appeared in Paris in 1300 to submit, Philip cast him into prison. His officials treated the wealthy Flemish cities so harshly that they revolted under Peter of Koninck. Philip's army was decisively defeated at Courtrai (q.v.) in 1302, and in 1305 he made peace, restoring Flanders to the son of Count Guy, the latter having died in prison.

Scholars have long disputed concerning the true character of Philip. On the one hand he has been represented as an avaricious, scheming monarch; on the other as a mild man, who was completely in the hands of bold counselors. But concerning the results of his reign there is no question. Feudalism was suppressed, and the power of the Crown vastly extended. In order to meet the financial needs of the State, the taxes were increased, the Jews persecuted, and their

property confiscated; and when these means were insufficient, the coinage was debased. Consult: Boutaric, *La France sous Philippe le Bel* (Paris, 1861); Funck-Brentano, *Philippe le Bel et la Flandre* (ib, 1896); Jully, *Philippe le Bel* (ib., 1869).

PHILIP V., LE LONG, i.e. the Tall (c.1294-1322). King of France from 1316 to 1322. He was the second son of Philip IV., and on the death of his brother, Louis X., was made Regent, as the Queen was with child. Her son died four days after birth and Philip proclaimed himself King (1316). Many opposed him, supporting the claims of his niece, the daughter of Louis X. The States-General, summoned by Philip in 1317, declared that women could not succeed to the throne. (See SALIC LAW.) In the same year Philip settled the long dispute with Flanders and acquired some territory from its Count. In 1320 a large number of peasants, known as Pastoureaux, led by some renegade clerks, demanded to be taken on a crusade. They committed horrible outrages, but were finally suppressed. Philip's reign is noteworthy for its many administrative reforms. He centralized the treasury receipts at Paris, suppressed the garrisons in castles not on the frontiers, confiscated for the Crown many feudal rights of taxation enjoyed by the nobles, and organized the army more efficiently. In other attempted reforms he was thwarted by opposition from the States-General. Consult Lechugeur, *Histoire de Philippe V. le Long* (Paris, 1897).

PHILIP VI. (1293-1350). King of France from 1328 to 1350, the first King of the House of Valois. He was the son of Charles of Valois, younger brother of Philip IV. At first Regent of France on the death of Charles IV., the proclamation of a king being deferred on account of the pregnancy of Charles IV.'s widow, he was crowned at Rheims on May 29, 1328, after the Queen had given birth to a girl. His right to the throne was denied by Edward III. of England, the grandson of Philip IV., who declared that females, though excluded by the Salic law, could transmit their rights to their children, and, therefore, insisted upon the superiority of his own claims. Philip's reign commenced gloriously, for, marching into Flanders to support the Count against his rebellious subjects, he wiped out the disgrace of Courtrai by vanquishing the Flemings at Cassel, August 23, 1328. The relations with England were very strained, and in 1337 the Hundred Years' War (q.v.) began, mainly through Philip's own fault. It was carried on languidly for several years, the only prominent incident being the destruction of the French fleet off Sluis, June 24, 1340. Philip was very extravagant and delighted in maintaining a brilliant court. The constant round of fêtes and tournaments was never interrupted, even when the war had well nigh exhausted the wealth of the country, for the money to carry them on was immediately provided by some new tax, by an arbitrary change in the coinage, or by some fresh confiscation. In 1338 the States-General declared that their consent was necessary for the imposition of new taxes, but Philip evaded all restraints which were imposed. In 1346 Edward III. landed in Normandy, ravaged the country to the environs of Paris, and totally defeated Philip at Crécy (q.v.). A truce was

then concluded by Papal mediation in 1347, but the kingdom had no sooner been released from war than destruction in another and more terrible form, that of the 'black death' (q.v.), appeared. Nevertheless the extravagance at the Court was as great as ever. During Philip's reign the royal domain was increased by the addition of Valois, Chartres, Anjou, Maine, Champagne, Brie, and Dauphiné, but diminished by the exchange of Navarre for Champagne and Brie. Consult Lavissee and Rambaud, *Histoire générale*, vol. iii. (Paris, 1894), for a good general sketch and bibliography. See FRANCE.

PHILIP II. (1527-98). King of Spain from 1556 to 1598. He was born at Valladolid on May 21, 1527, the only son of the Emperor Charles V. (q.v.). His education was chiefly in the hands of the clergy and he grew up a cold and bigoted man. In 1543 he was married to Maria of Portugal, and upon her death he espoused in 1554 Mary I. of England (q.v.). In 1555 Charles V. surrendered the government of the Netherlands to Philip, and in the following year resigned also the crown of Spain to his son, who had been previously invested with the sovereignty of Naples, Sicily, and Milano. The possession of Spain in the New World included the West Indies, Mexico, and a great part of South America. The early part of the reign of Philip proved very successful. He defeated a coalition formed against him by the Pope and France, his armies winning several battles, notably that of Saint-Quentin (1557), and France was compelled to sign on April 2-3, 1559, the Treaty of Cateau-Cambrésis (q.v.), which marked the abandonment of her rôle as an aggressive power on the side of Italy. Philip determined to stamp out opposition to Roman Catholicism in all his dominions, and this caused the revolt of the Netherlands (q.v.). This successful rebellion, and the enormous expenses it entailed upon Spain, ruined the prosperity of Philip's dominions. The naval supremacy of Spain, moreover, was shattered by the defeat of the Armada (q.v.), which Philip had sent against England in 1588. Besides the war against England, Philip was led by the affairs in the Netherlands to interfere also in the concerns of France. He has been sometimes accused of having instigated the Massacre of Saint Bartholomew, and he supported the Guises against Henry of Navarre (later Henry IV.), but all in vain. On May 2, 1598, the Treaty of Vervins (q.v.) was concluded with France. Against the Turks Philip was more successful. They were decisively defeated in 1571 by his half-brother, John of Austria, commanding the fleet of the Holy League (Spain, Venice, the Papal States), at Lepanto (q.v.). Portugal was conquered by Philip's general, the Duke of Alva (q.v.), after the direct male line of that country had become extinct in 1580. But these successes were unable to outweigh the ruin of Spanish commerce and industry. Philip died after a lingering illness on September 13, 1598. After the death of Mary of England in 1558, Philip married in 1559 Elizabeth, the daughter of Henry II. of France, and when she died in 1568, he married Anna, a daughter of the Emperor Maximilian II. By his first wife Philip had a son, the celebrated Don Carlos (q.v.), and by his fourth wife, his successor, Philip III. (q.v.). Philip II.'s character has been the subject of considerable historical controversy. There can

be little doubt that he was bigoted and morose, but, on the other hand, the popular view, which represents him as a cruel monster, is a false one. He seems to have been an idealist and a visionary, who believed firmly that he was benefiting humanity by his drastic measures. He was often open to appeals for mercy and leniency, but the Inquisition was permitted a free sway in Spain, and all liberty was crushed.

Consult: Prescott, *History of the Reign of Philip II., King of Spain* (Boston, 1855-56), which is valuable, but incomplete; Forneron, *Histoire de Philippe II.* (Paris, 1881-82); Philippson, *Westeuropa im Zeitalter von Philipp II., Elisabeth und Heinrich IV.* (Berlin, 1882); Mignet, *Antonio Perez et Philippe II.* (Paris, 1874); Lobkowitz, *Philippus Prudens* (Antwerp, 1639); Gachard, *Correspondance de Philippe II. sur les affaires des Pays-Bas* (5 vols., Brussels, 1848-79); id., *Lettres de Philippe II. à ses filles les Infantes Isabelle et Catherine* (Paris, 1884); id., *Correspondencia de Felipe II. con sus embajadores en la corte de Inglaterra, 1558-84* (4 vols., Madrid, 1888). See SPAIN.

PHILIP III. (1578-1621). King of Spain from 1598 to 1621. He was the son of Philip II. and is to be remembered chiefly for accelerating the ruin of Spain, which had begun under his father, by driving out in 1609 the Moriscos (q.v.), the most industrious and thrifty inhabitants of Spain.

PHILIP IV. (1605-65). King of Spain from 1621 to 1665. He took little part in the affairs of government, which from 1623 to 1643 were in the hands of his favorite Olivarez (q.v.). In spite of the latter's efforts for the encouragement of trade and industry, the decline of Spain was hastened by exhausting wars in Germany and with France. In 1640 Portugal conquered its independence, and by the Treaty of Westphalia Spain acknowledged the independence of the Netherlands. The Peace of the Pyrenees in 1659 was highly favorable to France. Philip's reign was disturbed also by insurrections in Catalonia and Andalusia.

PHILIP V. (1683-1746). King of Spain from 1700 to 1746, first of the Spanish Bourbon dynasty. He was directly descended on both sides from Philip II., and was born at Versailles, December 19, 1683, the son of the Dauphin Louis and Maria Anna of Bavaria, and grandson of Louis XIV. and Maria Theresa, eldest sister of Charles II. of Spain. The Archduke Charles of Austria, second son of the Emperor Leopold I., stood equally near the Spanish succession; but Charles II., dying without issue, left the kingdom by his last will to Philip, then Duke of Anjou (1700). Philip was at once proclaimed at Fontainebleau and at Madrid as Philip V. To defend this succession, which threatened to disturb the religious political balance in Europe, France and Spain became involved in war with the Grand Alliance, formed by England, Holland, and Austria, and joined by Prussia, Denmark, Hanover, Portugal, and finally Savoy. (See SUCCESSION WARS.) The Peace of Utrecht (April 11, 1713) secured the throne of Spain to Philip, but shorn of the Italian possessions and the Netherlands. Philip V. was distinguished 'for few faults and few virtues,' was weak-minded, and became almost imbecile before his death. His first wife, Marie Louise of Savoy, died in

1714, and with her death ended the influence the Countess Orsini had acquired over him, for Philip married Elizabeth Farnese of Parma, an energetic and ambitious woman. Her schemes for advancing the interests of her sons kept Spain embroiled throughout the reign. The minister Cardinal Alberoni (q.v.) directed his policy toward regaining the lost Spanish possessions in Italy and had to be removed because of the hostility aroused among the powers. In 1724 Philip abdicated in favor of his eldest son, Louis, but upon the death of the latter in the same year he resumed the crown, notwithstanding his increasing incapacity. In 1734-35 Don Carlos, son of Philip, wrested the Two Sicilies from Austria. In 1741 Spain entered into an alliance with France against Maria Theresa in the War of the Austrian Succession. (See SUCCESSION WARS.) Philip died at Madrid on July 9, 1746. He was succeeded by his second son, Ferdinand VI. (q.v.). Consult: Coxe, *Memoirs of the Kings of Spain of the House of Bourbon from the Accession of Philip V. to the Death of Charles III.* (5 vols., London, 1815), a work that is still of value, although new sources have come to light since it was written; Boudeillart, *Philippe V. et la cour de France, 1700-15* (Paris, 1890). See SPAIN.

PHILIP OF SWABIA (c.1177-1208). An emperor of the Holy Roman Empire. He was the youngest son of Frederiek Barbarossa and Beatrice of Burgundy. He was educated for the Church and in 1191 became Bishop of Würzburg. In 1192 he resigned his see. His brother, the Emperor Henry VI., gave him Tuscany in 1195 and in 1196 he succeeded to the Duchy of Swabia. In 1197 he married the Byzantine Princess Irene. On the death of Henry VI., in 1197, Philip endeavored to secure the Imperial crown for his brother's infant son, Frederiek (II.), but the German princes were unwilling to place the child on the throne, and Philip himself was chosen Emperor in 1198. But the Guelphs, under the leadership of Adolf, Archbishop of Cologne, put forward as a candidate Otho of Brunswick, who was crowned two months before Philip (1198), and in 1201 gained the support of Pope Innocent III. Philip fought bravely against great odds, and by bribes won over the Archbishop of Cologne and Hermann of Thuringia, with other powerful princes. In 1205 he was crowned by the Archbishop of Cologne, and captured the city, but let his rival slip through his fingers (1206). He made terms with Otho and with Innocent III. The former broke his promises, and Philip, making ready to attack him, was assassinated by Otho of Wittelsbach. Consult Winkelmann, *Philipp von Schwaben und Otto IV. von Braunschweig* (Leipzig, 1873-78).

PHILIP THE BOLD (1342-1404). Duke of Burgundy from 1363 to 1404. He was the fourth son of John the Good, King of France. He was present in 1356 at the battle of Poitiers (q.v.), and displayed such courage, venturing his own life to save that of his father, that he became known as *Le Hardi*, i.e. 'the Bold.' He shared his father's captivity in England, and on returning to France in 1360 received in reward of his bravery the Duchy of Touraine, and subsequently (1363) also that of Burgundy, being created at the same time the first peer of France. In 1369 he married Margaret, the daughter and

heiress of Count Louis de Male of Flanders. On the death of King Charles V., in 1380, he became Regent, together with his brothers, for his nephew, Charles VI. In 1382, at the head of a French army, he marched against Philip van Artevelde, the leader of the Flemish burghers in their revolt against their Count, and overwhelmed him in the battle of Roosebeke. Flanders, Artois, and Franche-Comté fell to him by the death of Louis in 1384. Energy and wisdom characterized his government; arts, manufactures, and commerce were encouraged, and his land was one of the best governed in Europe. When Charles VI. became insane (1392) the supreme control of affairs in France fell into the hands of Philip, and he used his power to strengthen his own line. He died at the château of Hall in Hainault, April 27, 1404. Consult Lavisse and Rambaud, *Histoire générale*, vol. iii. (Paris, 1894), and bibliography. See also FRANCE.

PHILIP THE GOOD (1396-1467). Duke of Burgundy from 1419 to 1467. He was the son of John the Fearless and Margaret of Bavaria. He was born at Dijon, June 13, 1396, and on the assassination of his father on the bridge of Montereau, succeeded to the Duchy of Burgundy. Bent on avenging the murder of his father, he entered into an offensive and defensive alliance with Henry V. of England at Arras in 1419, recognizing him as the rightful Regent of France, and heir to the throne after Charles VI.'s death. This agreement was sanctioned by the imbecile King himself as well as by the mother of the Dauphin, Queen Isabella, in the Treaty of Troyes (1420). The Dauphin (later Charles VII.), however, declined to resign his rights, and took to arms, but was defeated and driven beyond the Loire. Some disputes with the English concerning possessions in Brabant and elsewhere prompted Philip to threaten in 1429 to conclude a treaty with Charles VII. However, the English, by ceding to Philip the Province of Champagne, and paying him a large sum of money, restored him to their side. In 1429-30 Namur, Brabant, and Limburg were annexed to Burgundy, and in 1433 Countess Jacqueline ceded Hainault, Holland, and Zealand to Philip. Though much more powerful than his nominal superior, the King of France, Philip did not take the royal title. After the death of his wife, sister of the English Regent in France, the Duke of Bedford, he gradually drew nearer to Charles VII., and in 1435 tried to negotiate a peace at Arras between all parties in the Hundred Years' War. The English demands proving excessive, he made peace alone with the French King. The latter part of his reign was filled with trouble caused by the quarrels between Charles VII. and his son, the Dauphin Louis, afterwards Louis XI. (q.v.), who had fled from his father's Court, and sought shelter with Philip. Philip died at Bruges, July 15, 1467, deeply lamented by his subjects. Under him, Burgundy was the most wealthy, prosperous, and tranquil State in Europe; its ruler was the most feared and admired sovereign of his time, and his Court far surpassed in brilliancy those of his contemporaries. Knights and nobles from all parts of Europe flocked to his jousts and tournaments. In 1430, in honor of his marriage with Isabella of Portugal, his third wife, he established the famous order of the Golden Fleece (q.v.). De Baranté, *Histoire des ducs de Bourgogne*, vols.

iii.-vi. (2 ed., Brussels, 1834-40). See CHARLES VII.

PHILIP THE MAGNANIMOUS (1504-67). Landgrave of Hesse from 1509 to 1567. He was born on November 13, 1504, and succeeded to the throne on the death of his father, William II. In 1518 he began to govern in person. At first he showed no sympathy for the Lutheran doctrines, of which he was to become the champion, and in 1523 he married the daughter of the Catholic Duke George of Saxony. In 1525, however, he was definitely won over to the cause of the Reformation. At the same time he aided in suppressing the Peasants' War. Philip became one of the chief leaders of the Reformation in Germany, and together with the Elector John of Saxony formed in 1526 the Protestant League of Gotha and Torgau. In 1529 he arranged the celebrated disputation between Luther and Zwingli at Marburg. It lasted for three days (October 1st-3d), but the two parties were unable to agree on the doctrine of the Eucharist. Philip himself, however, began to lean strongly toward the Swiss side. In 1531 he formed together with the Elector of Saxony and other Protestant princes the League of Schmalkald (q.v.). On March 4, 1540, Philip married a second time, though his first wife was still living. Luther and Melancthon had consented to this bigamy, and the revelation of this fact caused a great scandal. In the Schmalkald War, which broke out in 1546, Philip did his best for the Protestant cause, but the treachery of Maurice of Saxony, his son-in-law, who joined Charles V., made matters hopeless. At the battle of Mühlberg on April 24, 1547, Philip was made prisoner and placed in close confinement. He was liberated in 1552 by the action of Maurice, who deserted Charles and rejoined the Protestant cause. Philip died on March 31, 1567, leaving four sons, among whom Hesse was divided. Consult: Rommel, *Philipp der Grossmütige, Landgraf von Hessen* (Giessen, 1830); Ranke, *History of the Reformation in Germany* (Eng. trans., London, 1845-47); Janssen, *History of the German People at the Close of the Middle Ages* (Eng. trans., ib., 1896—).

PHILIP THE MAGNANIMOUS, ORDER OF. A Hessian order of merit with five classes, founded by Grand Duke Ludwig II. in 1840. The decoration is an eight-pointed cross of white enamel, with the motto *Si Deus nobiscum, quis contra nos*.

PHILIP, KING (?-1676). A famous Indian chief, son of Massasoit; called by the English King Philip, though his Indian name was Metacomet. He became sachem of the Wampanoags, who were settled in the Rhode Island Country in 1662, and in the same year went to Plymouth and promised to maintain friendly relations with the English colonists and not to cede any territory without their knowledge. About 1670 his friendly intentions began to be suspected on account of frequent meetings of the tribes and many murders of white settlers. In view of these suspicions, Philip and the principal tribesmen were summoned to meet the whites and explain their movements. This they did, and also agreed to surrender their arms; but it was only a truce, and preparations for war were still secretly carried on by the Indians. An Indian convert named Sausamon revealed to the colonists the prepara-

tions made by Philip, and was murdered by the Indians. In revenge for the execution of his murderers by the whites, the Indians killed eight or nine colonists, and open hostilities were begun in June, 1675. The Indians did not venture to meet the colonists in battle, but burned or attacked a number of their settlements, including Swansea, Brookfield, Deerfield, and Hadley, and laid ambushes for the settlers. In December, 1675, Governor Josiah Winslow led a force of 1000 men against the Narragansets, with whom Philip had formed an alliance, took by storm a fort said to have contained 4000 Indians, near the present location of Kingston, R. I., destroyed their village of 500 wigwams, and put to death 500 of their warriors and twice as many Indian women and children. The war went on for the first six months of 1676, and was marked by burnings and massacres at Weymouth, Groton, Medfield, and Lancaster, Mass., and at Warwick and Providence, R. I. But the increased efforts of the colonists soon struck demoralization into the ranks of the Indians. A substantial reward was offered by the Government for every Indian killed in battle, and many Indian women and children were captured and sold into slavery. A force under the command of the great Indian fighter Capt. Benjamin Church (q.v.) hunted Philip from place to place, at last locating him through the aid of a friendly Indian in a swamp near Mount Hope, where he was killed by another Indian while trying to escape. His body was quartered, on a Thanksgiving Day especially appointed, and his head was sent to Plymouth, where it was long kept on a gibbet. During this war some 600 colonists were killed, 600 buildings burned, and 13 towns destroyed, but of the two once powerful Indian tribes it is said that less than 200 individuals were left. The cost of the war was estimated at \$1,000,000. Consult: Fiske, *The Beginnings of New England* (Boston, 1889); Palfrey, *History of New England* (ib., 1864); and Doyle, *The English Colonies in America*, vol. iii. (New York, 1889).

PHILIP, GOSPEL OF. See APOCRYPHA, section on *New Testament*.

PHILIP, THE ADVENTURES OF. A novel by Thackeray (1862). This sequel to *The Shabby Genteel Story* appeared in the *Cornhill Magazine* (1861-62). Philip Firmin, the attractive, high-spirited hero, was almost ruined by his unspeakable father, the doctor, ignored by his relatives, helped by the Pendennises, and happily married to Charlotte Bayne.

PHILIP, JOHN WOODWARD (1840-1900). An American naval officer, born in New York City. He was appointed to the United States Naval Academy at the age of sixteen, became midshipman in 1861, and during the Civil War served in the Gulf blockading squadron, the James River fleet, and the South Atlantic blockading squadron, acting as executive of the *Chippewa*, *Purnee*, and *Montauk* at the siege of Charleston. In July, 1862, he was promoted to be lieutenant, and in July, 1866, to be lieutenant-commander. After the war he was executive successively of the *Hartford* and the *Richmond*, was placed in command of the *Monocacy* in June, 1873, and in December, 1874, was commissioned commander. From 1874 to 1876, on leave of absence, he commanded one of the steamers of the Pacific Mail Steamship Company, running between San Fran-

cisco and Hong Kong, and in 1877, again on a leave of absence, he commanded the 'Woodruff Scientific Expedition Around the World.' He was promoted to be captain in 1889, commanded the Boston Navy Yard from 1894 to 1897, and in the latter year was placed in command of the battleship *Texas*, which, still under his command, took a prominent part in the naval battle of Santiago during the Spanish-American War. In August, 1898, he was promoted to be commodore and was placed in command of the second squadron of the North Atlantic fleet, and in March, 1899, he was promoted to be rear-admiral and made commandant of the Brooklyn Navy Yard.

PHILIP NERI, SAINT (1515-95). The founder of the Congregation of the Oratory (q.v.). He was born at Florence of a distinguished family, July 21, 1515. On the death of his parents in 1533, he was adopted as his heir by a wealthy relative, with whom he lived for a time at San Germano, near Monte Cassino. But he relinquished these prospects to devote himself to the service of God, and on the advice of the Benedictine monks of Monte Cassino, came to Rome to make his theological and philosophical studies (1534-37). He devoted himself to works of mercy, once sold his books to feed the poor, and in 1548, in conjunction with his confessor, Persiano Rosa, founded the Confraternity of the Holy Trinity to care for the needs of the vast numbers of pilgrims who came to Rome. This brotherhood is said to have provided hospitality for not less than 600,000 pilgrims in the jubilee year of 1625, and for a quarter of a million in 1825. (See Morichini, *Instituti di pubblica carità* Rome, 1870). Having long refused holy orders from motives of humility, he finally received them in 1551, and began as a priest a still more remarkable career of devotion and influence. Inspired by the tidings of the heroic labors and death of Saint Francis Xavier, he determined to go to the Indies, and assembled 20 companions; but he was finally convinced that Rome was meant to be the field of his work. The objects of the informal association out of which the Congregation of the Oratory later developed were the instruction and training of the young and uneducated. As a means of withdrawing them from dangerous amusements, sacred musical entertainments (hence called by the name of *oratorio*) were held in the oratory, at first consisting merely of hymns set to popular tunes, but afterwards partaking more of the nature of sacred dramas. The music was composed by the first musicians of Rome. Palestrina was a spiritual child of Philip's, and died in his arms. It was in the lectures originally prepared for use in the oratory that, at Saint Philip's instance, the gigantic Church History of Baronius had its beginning. The personal character of Philip, the unselfish devotion of his life, his unaffected piety, genuine love of the poor, kindly and cheerful disposition, and perhaps as much as anything else a certain quaint humor which pervaded many of his sayings and doings, contributed to popularize his work. The development of the Oratory was almost unconscious. In 1564 Philip was requested by his fellow-countrymen the Florentines in Rome to take charge of their Church of San Giovanni near the Ponte Sant' Angelo; he declined, until Pope Pius IV. gave him permission to hold it while still retaining his residence in his humble

cell at San Girolamo. In 1574 the Florentines erected a new oratory near the church, and the exercises were held there for a time; the following year he saw himself compelled to provide for the permanence of his work on a larger scale, and, taking the small Church of Santa Maria in Vallicella, he pulled it down and built a large new one. Here he was authorized by Gregory XIII. to found a definitely organized congregation in the same year. He still remained at San Girolamo, and refused to appear as the head and founder of the new society, until in 1583 he was expressly commanded by the Pope to take up his residence in the new house. Then his associates elected him superior for life, despite all his protests. Ten years later, however, he prevailed upon them to let him lay the burden aside, and Baronius was chosen in his stead. He died May 26, 1595. Paul V. beatified him in 1615 and Gregory XV. canonized him in 1622. Called the Apostle of Rome, he remains to this day emphatically the popular saint of the Roman people, who observe his feast-day with great devotion. From 1726 until the Italian occupation, the popes were accustomed to go in solemn state on this day to visit his tomb and to say mass there. Consult the contemporary lives of Gallonio, Barnabei, and Bacci (the two first contained in the *Acta Sanctorum*); English translation of the last by F. W. Faber (London, 1847); a modern biography by Cardinal Capecepatro (Naples, 1879; Eng. trans., London, 1894); *Maxims and Counsels of Saint Philip Neri* (Dublin, 1890); Cardinal Wiseman, *Panegyric of Saint Philip Neri* (London, 1856).

PHILIPP, ISIDOR (1863—). A French pianist of Austrian birth. He was born at Pesth, but early removed to France. In 1879 he entered the Conservatory as a pupil of Mathias, and later studied under other famous teachers of that institution. He was intimately connected with the musical life of Paris, and did much to spread a love for classical chamber music. He was one of the most popular artists appearing at the Lamoureux concerts, and was equally well received throughout the large cities of France. In London and Brussels he was also highly esteemed. His published compositions have been successful, particularly his editions of classic studies. Together with Loeb and Berthelier, he organized a series of concerts given in the Salle Erard, which concerts were largely devoted to the presentation of new French compositions. He was also co-founder and subsequent president of the Société d'Art.

PHILIPPA OF HAINAULT, há'nó' (c.1314-69). An English queen, wife of Edward III. and daughter of William the Good, of Holland and Hainault. She was married in 1328 to her cousin, Edward of England, by Papal dispensation, and brought him a large dowry and valuable Continental allies during the war with France. It is said that she summoned the forces which defeated the Scottish troops at Neville's Cross (q.v.) in 1346. Philippa was mother of the Black Prince, Edward. She was a patron of Froissart and was very popular among the English common people. Queen Philippa is notable because she aided in maintaining and strengthening that close connection of England and Flanders, so important for English commerce.

PHILIPPE DE THAUN. See THAUN.

PHILIPPEVILLE, fê'lêp'vel'. A fortified seaport and the capital of an *arrondissement* in the Department of Constantine, Algeria, 38 miles north-northeast of the city of Constantine, on the Gulf of Stora, between Cape Boujaroun and Cape de Fer (Map: Africa, E 1). Laid out in 1838 by Marshal Valée, on the ruins of the ancient Russica, it is one of the prettiest towns in Algeria, and thoroughly French in its character. Philippeville is the chief railway station for the Department of Constantine, and is connected by steamer with Marseilles and Algiers. It has several public offices, a large hospital and dispensary, Catholic and Protestant churches, public library and museum, theatre, etc. It has a distillery, tanneries, and cork manufactures. In the vicinity at Filfila are quarries of marble and iron mines. The town is an important entrepôt of the commerce of the east of Algeria and the Sahara, and the country in the vicinity is picturesque and fertile, producing grain, tobacco, cotton, and fruits. Its fine outer and inner harbors of 125 acres are protected by two breakwaters. The total annual value of its imports and exports is \$17,500,000. Population, in 1901, 21,251.

PHILIPP GALEN, gâ'len. See LANGE, ERNST P. K.

PHILIPPI (Lat., from Gk. Φιλίπποι). A city of Macedonia. It was named after Philip II. of Macedon, who conquered it from Thrace, up to which time it had been called Crenides, or 'the place of fountains,' and enlarged it because of the gold mines in its neighborhood. It was situated on a high hill on the southern edge of a great plain, and about nine miles from the coast, where was the harbor Neapolis. With the rest of Macedonia it fell under the Roman power in B.C. 168, and was joined to the District of Amphipolis. In B.C. 42 it was the scene of the battles between Brutus and Cassius on the one side and Mark Antony and Octavian on the other, which resulted in the destruction of the former. In consequence of this victory, Augustus subsequently made it a Roman colony and conferred on its inhabitants the *jus Italicum*, which exempted them also from the land tax. Here about A.D. 50 the Apostle Paul founded a Christian church, to which is addressed the Epistle to the Philippians. An epistle to the same church is also preserved among the writings of Polycarp. The ruins are still called in Turkish Felib-edjik.

PHILIPPI, FELIX (1851—). A German dramatist, born in Berlin. He early entered journalism, and in 1875 removed to Munich, where he contributed to various French and German papers. After about 1884, however, he devoted himself almost wholly to the writing of plays, and ultimately became one of the most popular contemporary dramatists in Germany, his plays being produced also in other countries and being given with considerable success in the German theatres in New York City. As a playwright he is classed with the modern realistic school. His plays include: *Der Advokat* (1884); *Irrlicht* (1885); *Daqmar* (1886); *Meeresleuchten* (1888); *Das alte Lied* (1889); *Die kleine Frau* (1891); *Der verlorene Sohn* (1892); *Wohlthäter der Menschheit* (1895); *Der Dornenweeg* (1895); and *Wer Wars?* (1896).

PHILIPPIANS, EPISTLE TO THE. One of the New Testament letters, whose authorship is

generally assigned to Paul. It was written to the church at Philippi to correct tendencies toward faction and self-seeking among its members (ii. 1-4, 14; iv. 2-5), to warn them against evil influences in their midst (iii.), to encourage and strengthen them in their Christian life and work (i. 12-30; ii. 12-16; iv. 1, 4, 6, 8), and to thank them for their practical ministry to the Apostle's needs in his imprisonment (iv. 10-19). It differs from the principal Pauline Epistles in the marked absence from its contents of controversial topics, while, on the other hand, it is unlike most of the subordinate writings of the Apostle in containing passages which have formed the gathering points of considerable theological debate. These are chiefly the notable Christological passage of the second chapter (vs. 5-11) and, though to a much less degree, the well-known soteriological passage of the third chapter (vs. 3-16).

In spite of the denial of the Epistle's Pauline origin by the Tübingen school (1845) and by as recent and able a scholar as Holsten (1898), the letter is to-day almost universally accepted as from the Apostle—its rejection by the modern Dutch school of criticism (1882) merely forming a part of their peculiar negative position with regard to all the New Testament books. A phase of this Dutch critical attack, however, is the denial of the Epistle's integrity, in which position certain outside the school have joined (Spitta, 1893; Clemen, 1894). But, though there are recognized difficulties in its sequence of thought, especially in the connection of the third chapter with its preceding and following context, the letter's unity is generally maintained by critics to-day. Scholars have almost without exception settled upon Rome, during Paul's first imprisonment, Thiersch (1879) and Macpherson (1892) being practically alone among later writers in the assertion of an origin at Casarea before Paul's voyage to Rome.

That which may be said to be of chief interest in the criticism of the Book is the question of its relative order to the other Epistles of Paul's first Roman imprisonment. The opinion more generally in favor to-day is that it is the last of this captivity group. It is argued that (a) the large size of the Church of Rome (i. 12-14); (b) the evidence of success from Paul's evangelistic work (i. 12-18), which would follow the statements made in Colossians and Ephesians of desire for such success (Col. iv. 3-4; Eph. vi. 19-20); (c) the several journeys between Philippi and Rome involved in the Philippians' ministry to the Apostle (ii. 25-27; iv. 18); (d) the desertion of the Apostle by his friends (ii. 19-21), which shows itself to be the climax of Col. iv. 11 and at the same time stands in contrast to Col. iv. 10-14 and Philemon 23-24; (e) the expectation of the near approach of his trial and the decision for life or death (i. 20-22; ii. 17, 24-26; iii. 10)—that these all show more naturally a later rather than an earlier date of writing. On the other hand, it is held that the similarity of much of the contents of the Epistle to the characteristic thought of Romans, and of much of the contents of Colossians and Ephesians with that which marks the thought of the pastors, show in both cases a state of mind on the Apostle's part which would most naturally fit in with a nearness in composition of the respectively related Epistles. Whatever may be said,

however, as to the reasonableness of either line of argument, it is quite clear that the passage regarding the variant preachers in Rome (i. 14-18), with its bearing upon the state of the Roman Church when the Apostle wrote his letter to it, must be fully understood before the question of the date of this Philippian letter can be finally settled. To this study is being directed to-day.

PHILIPPICS. See CICERO; DEMOSTHENES.

PHILIPPINE ISLANDS. An archipelago forming the most northern group of islands in the Malay or Eastern Archipelago. It lies wholly within the tropics. The land surface extends between latitudes 21° 10' and 4° 40' N., 1150 statute miles; the east and west limits are longitude 116° 40' and 126° 34' E., making about 650 miles. The most northern land in the Philippines is Y'Ami Island, of the Batanes group; the most southern is Balut Island, of the Sarangani Islands, south of Mindanao; the most western is Balabac Island, north of Borneo; and the most eastern is Sancó Point, on the east coast of Mindanao. The archipelago is bounded on the north and west by the China Sea, on the east by the Pacific Ocean, and on the south by the Sea of Celebes and the coastal waters of Borneo. It is 93 miles distant from foreign territory on the north (Formosa); 31 miles from Balambangan, an island near Borneo, on the south; 510 miles from the Pelew group (German) on the east, and 515 miles from Cochín-China (French) on the west.

The archipelago numbers about 1600 islands, most of them very small, and having altogether about 11,500 miles of coast line. Two of them, Mindanao and Luzon, are, however, classed among the larger islands of the world, and eleven islands, Luzon, Mindanao, Samar, Panay, Negros, Palawan (Paragua), Mindoro, Leyte, Cebú, Masbate, and Bohol, are of primary geographical importance. The others are mainly dependent islands or islets along the coast of the large islands or subordinate archipelagoes like the Sulu Islands. The area of the total land surface is computed at 127,853 square miles, or a little larger than the New England States, New York, and New Jersey together. Mindanao (45,559 square miles) and Luzon (43,075 square miles) comprise about seven-tenths of the total land surface, the area of the other leading islands being: Samar, 5198 square miles; Negros, 4839; Panay, 4752; Palawan, 4368; Mindoro, 4050; Leyte, 3872; Cebú, 1668; Bohol, 1400; and Masbate, 1230. The total water surface within the limits occupied by the archipelago is 705,115 square miles.

TOPOGRAPHY. This immense labyrinth of islands forms that part of a vast submarine plateau which has emerged above the ocean. The surrounding waters are shallow, for the most part not over 200 feet in depth, showing that the wide plateau on which the islands stand nearly approaches the surface. But strewn here and there over the sea floor are troughs and hollows and wide depressions, particularly to the west of Luzon and Mindanao, where greater depths are found. There is nothing approaching oceanic depths till the eastern edge of the submarine plateau descends to the Pacific deeps from 100 to 300 miles east of the archipelago. In the south three lines of islands stretch like isthmuses between the main archipelago and the southern lands. In the northwest is the most regular and best developed of these isthmuses, stretching from Mindoro to North Borneo, the long, narrow island of Palawan forming more than half its extent. In the centre the Sulu Archipelago connects the western terminus of Mindanao with the northeastern point of Borneo; and in the southwest the great peninsula of Celebes with the Sanguir Archipelago and other islands forms another isthmus, sweeping around to the south of Mindanao. These ridges are extended throughout the archipelago in the form of mountain ranges, from south to north, and form a large part of its relief. From the southern coast of Mindanao to the north of Luzon the mountains are disposed in a line with or parallel to the southern isthmuses. The whole interior is essentially mountainous, the Cordilleras extending north and south, their highest peaks ranging from 3720 to 10,312 feet (Apo in Mindanao), with outlyers and ramifications partly filling the gaps between the ranges. Narrow plains occur between the mountains and wider ones where the river valleys broaden near the coast, and are enriched with alluvial deposits. Mountains are the backbone of all the islands, though in Leyte there are no mountains of special prominence. Three ranges in Luzon and four in Mindanao are the dominating features in the topography of those largest islands. The wider plains are in the basins of the larger rivers of Mindanao and Luzon. Owing to the predominance of mountains, the area of tillable lands is not believed to be one-third of the total area.

HYDROGRAPHY. In the smaller and narrower islands the mountain chain which is the backbone of each island is the great central water-parting, streams flowing to the sea on either side of it in short, straight courses. Mindoro, for example, has about 60 independent little rivers. The drainage of the larger islands is more complicated, the parallel arrangement of the mountain chains giving space for the development of considerable streams. Among them is the Rio Grande de Cagayan (q.v.), with a drainage basin of 16,000 square miles, or much more than one-third of Luzon. All the interior waters of North-eastern Luzon are tributary to the Cagayan, reaching the China Sea on the north coast of the island. All the interior waters of Central Luzon, south of the Cagayan basin, are included in the system of the Rio Grande de la Pampanga, which empties through a wide delta into Manila Bay. The mountains are so near the sea in East Luzon that the rivers of that coast are of small importance excepting the Bicol in the southeast, which floats small vessels; but in the northwest the

Agno has 11 feet of water on its bar at high tide, which gives some importance to the port of Dagupan at its mouth. The Pasig is only 12 miles long, but as it connects Bay Lagoon (q.v.), or Laguna de Bay, with Manila Bay through the chief port of the island, it is a commercial highway of importance. The river systems of Mindanao, confined within the parallel ranges, have chiefly a north and south direction and are more important for navigation than those of Luzon. The Rio Grande de Mindanao, one of the largest rivers in the Philippines, drains the central basin of the island, carries the waters of many tributaries to the Celebes Sea on the west coast, and is navigable for gumbats as far as Lake Lagusan. The Rio Agusan (q.v.) rises about 25 miles from the south coast, and reaches the sea on the north coast, nearly dividing the island. It is navigable for a few miles from its mouth. The most important lakes in Luzon are: Laguna de Bay, 25 miles long and 21 miles wide, which receives numerous small streams from the mountains around it, and Bombon, 14 by 11 miles in extent, Taal volcano rising amid its waters. The largest lakes of Mindanao are Maguindanao, in the centre, and Malanao, near the north coast. Smaller lakes are scattered over the islands.

CLIMATE. As the archipelago is wholly within the tropics, the climate is naturally very warm. From November to February inclusive, the most temperate months, the temperature ranges from 75° to 80° F. The hottest months are April, May, and June, when the monthly mean ranges between 81° and 83°. The intermediate temperatures are in March, July, August, September, and October, when the mean is from 79° to 81°. The temperature at Manila rarely rises above 100° in the shade, and does not fall below 60°. The prevailing atmospheric humidity intensifies the discomforts of heat, from which there is little relief in the three hottest months; but in December, January, and February the nights are fairly cool. As the mean temperature for the year varies merely by a few degrees, only two seasons are recognized. In the wet season, from June to October, five months, the rains are very heavy in the interior and on the west coast, because the moist southwest monsoon there prevails. The east coasts do not share in the excessive precipitation, because they are shielded by the mountains. In the dry season, from November to May, the comparatively dry northeast monsoon prevails, there are many fair days, and the precipitation is greatest on the east coast. The rivers often overflow their banks during the wet season and wide areas in the larger islands are submerged; but the floods are not feared so much as the cyclonic storms of wind and rain known as typhoons, which seldom occur south of 9° N. latitude, but north of that line sometimes destroy the lives of thousands of persons and wreck many vessels and villages. Cyclones are most frequent in July, August, September, and October, when these whirling winds from the Pacific occasionally sweep the whole archipelago north of Mindanao. The most terrific of these storms recorded in the Philippines struck Manila in 1882, traveling at a velocity of 140 miles an hour.

The danger from epidemic diseases is not great except for the occasional visitations of cholera, which is difficult to control, as has been proved since the United States acquired the islands.

Smallpox is always prevalent, but very seldom attains wide-spread development. The bubonic plague has never gained a strong foothold, though in 1901-02 the most strenuous efforts were required to suppress it. Malaria is prevalent in some islands, especially Mindoro, Balabac, and parts of Palawan, Luzon, and Mindanao, but large districts are entirely free from it. Malarial fevers and digestive troubles are the chief diseases. On the whole the health of the natives is fairly good, but the climatic conditions, except in some districts, are not favorable to long residence by Americans or Europeans. It is fortunate that some places among the mountains afford health resorts to which white persons may go for recuperation. Such an asylum is the elevated plateau of the small province of Benguet, 150 miles north of Manila, where, during the hottest month of the year, the temperature is not over 70° F. at midday.

FLORA. The vegetable life is rich and varied, with very few distinctive species, but some plants that are transitional between the flora of Formosa on the north and Borneo on the south. Sixty species of large trees afford the most valuable hard woods for the use of the ship-builders and cabinet-makers. Many other trees are so hard that they cannot be cut by the ordinary circular saw. The bamboo grows in numerous varieties, and, as in other parts of the Malayan Archipelago, is indispensable to the natives. The cocoa palm flourishes everywhere and many of the ripe nuts are collected in rafts and floated to market. The oil is used in cooking and as an illuminant. Other palms are very numerous. The banyan is common and grows to enormous dimensions, and the cinnamon, clove, and pepper are found wild in the southern islands. About 1200 genera and 5000 species of plants have thus far been recognized by botanists. Economically the most valuable of the wild plants is Manila hemp, the fibre of a wild plantain (*Musa textilis*). The plant closely resembles the edible banana in appearance and grows best on shaded hillsides at moderate elevations. The export crop is raised on plantations, which yield, when carefully managed, an annual return of 30 per cent. on the capital invested. This fibre is not successfully raised elsewhere except on a few plantations in North Borneo. Practically all the cultivated plants of the South Asian island world are successfully raised, including rice, sugar, tobacco, coffee, cocoa, maize, and sweet potatoes.

FAUNA. The islands are poor in indigenous mammals. The most important animal is the carabao or water buffalo, which is caught young, tamed, and universally employed as a draught animal, while his tough flesh is valued by the natives as meat. He is usually docile, but is slow and lazy and during the heat of the day will not work more than two hours at a time without his mud bath. The female gives abundant milk, from which *ghee*, a kind of butter is made. The hide makes valuable leather. The timarau, a small buffalo living in the jungles of Mindoro, has never been tamed; it often attacks and kills the larger carabao. A small humped variety of cattle are raised in large numbers for beef on some of the islands. Goats are common and are utilized both for milk and flesh. There are several species of deer, and both wild and domesticated hogs are very abundant. The larger horse as known in America and Europe, does not thrive, but the Philippine

pony, originally from Spain, is an excellent saddle horse, and useful in teams as a carriage horse, but not strong enough for heavy work. The carnivora have no large representatives, and only a small wild cat, two species of civet cats, and the binturong are conspicuous. The islands have nearly 600 species of birds, among which are the jungle fowl, hornbill, fruit pigeon, the snipe, curlew, and other waders; also the species of swift whose nests (edible birds' nests) are highly esteemed in China as an article of food. Marine fish are far more important than fresh-water fish and form the largest part of animal food, the natives also eating many varieties of 'shell fish.' The pearl oyster, yielding a considerable quantity of shell and jewels, is fished in the Sulu Archipelago. Crocodiles and snakes are abundant. Swarms of locusts sometimes devastate the fields, and rice and tobacco have other insect enemies.

GEOLOGY AND MINERAL RESOURCES. The geology of the archipelago has not yet been systematically studied. In broad outline the islands appear to consist of ancient eruptive rocks that have been covered by volcanic outpourings of the Tertiary, Quaternary, and present epochs, and in the lower levels by alluvium. Fossils are not found in the higher altitudes, and deposits of marine fossils are of small extent in recent geological times. There are twenty-three well-known volcanoes, of which eleven are more or less active. The most famous among them, and perhaps the most beautiful volcanic cone in the world, is Mayón, or the volcano of Albay, near the Bay of Legaspi, in Southeastern Luzon. Mayón is 8274 feet in height, and some of its eruptions in the past three centuries have been very serious. The surrounding country has been well-nigh buried under its streams of lava, and its clouds of volcanic dust have been carried through the air as far as the coast of China. Another remarkable volcano is Taal, which is an island in the middle of Lake Bombon, Luzon, with an area of 220 square miles, built up from the bottom of the lake by the outpourings from several craters. The archipelago is a centre of seismic as well as volcanic energy, and the volcanic centres are often the sources of the severest earthquakes. Most of the very violent shocks from which Manila has suffered, for example, have radiated from the Taal centre. For the eighteen years 1880-97 there was an average of 53.4 earthquake days in the year, or 4.5 per month.

The mineral resources are supposed to be very large, but their extent is not yet known. Better transportation facilities and more capital and labor will be required to develop these sources of wealth. True coal has not been found, but the highly carbonized lignite of Tertiary age which takes its place is supposed to be the chief mineral product. It is a fairly satisfactory fuel for steamers, and is widely distributed over the archipelago, especially in Luzon, Mindoro, Masbate, Panay, Samar, Cebú, Negros, and Mindanao. At present it is mined chiefly in Cebú, where as soon as the transportation shall have been perfected the output is expected to be 5000 tons a month. Gold is found in many localities, and has long been mined by natives, employing very rude and wasteful methods. Explorations have proved that the alluvial deposits in many parts of Luzon, Mindanao, and other islands are extensive, and gold-bearing quartz is found among the mountains of Northern Luzon, in Mindanao, and else-

where, some of it being crushed by the natives between heavy stones and the metal extracted by washing. The prospects of gold-mining in Luzon are very favorable. Copper ore is reported from many islands, but the deposits have not yet been worked to any extent. Iron ore is abundant in Luzon, Cebú, Panay, and other islands. Some of the ore of Luzon yields 85 per cent. of pure metal, but thus far the ores are almost unworked except to a small extent in Luzon. Silver occurs in association with lead; sulphur may be obtained in large quantities around some of the volcanoes; and salt, gypsum, and a few other minerals of commerce are found.

AGRICULTURE. Though agriculture is the most important source of wealth, it is in a very backward condition. Farming implements are of the most primitive sort. The cultivator, farm roller, and many other implements were never seen in the Philippines till the United States authorities opened the Government experimental farm. The natives do not understand the use of fertilizers, and know so little about forage crops that all the fodder for the horses and mules in the Government service has been imported. The indolence of the natives has also been unfavorable to large agricultural development. Nearly all the tilled lands are between sea level and 700 feet above the sea. The staple products in order of importance are Manila hemp (abaca), tobacco, sugar, coffee, and rice. Hemp is produced chiefly in the provinces of Luzon south of Manila, in the islands of Samar and Leyte, and on a smaller scale in the other islands north of Mindanao, and on the north coast of Mindanao. The bast, or fibrous outer leaf, yields the coarse, strong fibre which is the best material for sail-cloth and cordage. From the fibre yielded by the inner stalks are woven fabrics that are superior in softness and lightness. These fabrics are seldom exported, but the bast, of which, under the best conditions, 3000 pounds of the acre are produced, is the greatest export commodity, the average yearly shipments amounting to nearly 100,000 long tons. Cotton and ramie fibre are also produced to some extent, but cotton has declined, owing to the increased use of foreign textiles. Tobacco is of excellent quality, though it does not equal the favorite grades of the Cuban crop. The best leaf is grown on the wide plain of the Rio Cagayan (Isabela and Cagayan provinces), North Luzon. This favored tobacco region supplies most of the leaf sent to foreign lands or manufactured in Manila. The inferior, though good, tobacco grown in the more southern islands is chiefly consumed at home, but the leaf of North Luzon is famous throughout Southeastern Asia and many Western countries. Sugar-cane, grown in all the islands, is of great importance, and though it is cultivated with little intelligence, and raw sugar is produced by the crudest methods, its value for export is second only to that of hemp. The coffee of Luzon and Mindanao is of excellent quality, comparing favorably with Java, but the crop has declined on account of insect enemies. Rice is grown everywhere, and is the great food staple of the common people. It was formerly exported to China, but for years the supply has been short of the home demand, and large quantities are imported from Cochin-China. Maize thrives throughout the archipelago and is grown especially on land that is not fitted for rice. While its use as food is

increasing, many natives do not eat it. Among other products are cocoanuts, cocoa, wheat, indigo, sesame, peanuts, many varieties of vegetables, and spices in the south. Large quantities of copra, the dried meat of the coconut, are prepared for export. The pastoral industries are extensive. Some of the islands, as Masbate, have comparatively little tilled ground and depend more largely upon live stock. It is estimated that Masbate has 10,000 carabaos, 55,000 cattle, and 5000 horses. Cattle of a small humped variety are raised for beef on several islands. Swine and fowls are found in every native settlement. The Government experimental farm near Manila is for the purpose of encouraging the production of crops. Experiments with alfalfa and other forage plants have been very successful, and most of the vegetables grown in the United States, excepting melons and white potatoes, yield well. The Government distributes seeds and is giving special attention to coffee-growing. Very little land is owned by the peasantry, who rent their small holdings, paying half the crop to the owners. About 500,000 acres of the best tillable lands are owned by three of the Roman Catholic societies which do not encourage thrifty farming; it is likely that their lands will be purchased by the Government and sold to the tenants. The settlement of the land question is of the highest importance, as it is impossible in most cases to give a safe title to lands.

MANUFACTURES. The most important manufactures are the products of the tobacco works. The largest tobacco factory in Manila has over 10,000 employees. Most of the natives smoke home-made cigars, and over 150,000,000 cigars are annually exported. The leaf is cured and manufactured by means of modern machinery, many of the cigarette machines are worked by steam, and Manila is the chief centre of all tobacco products. Fabrics of Manila hemp, wool, cotton, silk, and piña fibre are woven on hand looms; and bamboo, rattan, palm leaves, and other material are used with intelligence and skill in making mats, hats, bags, cigar cases, and a large variety of other articles. Rope, soap, leather, sugar, and some other commodities are made by antiquated and imperfect processes, but much skill has been developed in erecting the better class of buildings, and in making furniture and wood carvings.

COMMERCE. Trade relations with foreign countries have grown rapidly since law and order were restored throughout most of the islands about the beginning of 1900, as the following table, giving the value of exports and imports, shows:

	1900	1901	1902
Exports.....	\$19,751,068	\$23,214,948	\$29,000,000
Imports.....	20,601,436	30,279,406	33,342,166

The large increase in the trade between the Philippines and the United States is shown by the following table:

	1898	1899
Exports to the United States.....	\$3,829,003	\$4,409,774
Imports from the United States....	127,804	404,171

	1900	1901	1902
Exports to the United States.....	\$5,971,208	\$4,420,912	\$6,612,700
Imports from the United States.....	2,635,624	4,014,180	5,251,867

The trade in 1901 with the other countries that are most important in Philippine commerce is indicated in this table:

	United Kingdom	Hong Kong	British East Indies
Imports from.....	\$6,956,145	\$3,529,322	\$2,820,797
Exports to.....	10,704,741	5,067,547	1,314,084

	Spain	France	French East Indies
Imports from.....	\$2,166,866	\$1,684,233	\$1,914,238
Exports to.....	1,656,400	1,934,256	1,483

The exports consist very largely of agricultural products. Manila hemp and sugar, the leading staples of the islands, are the principal factors in the trade, their combined value usually amounting to more than 75 per cent. of the total export valuation. In 1900 the value of the principal exports was: Manila hemp, \$13,290,400; sugar, \$2,397,144 (smaller than usual); copra and cocoanuts, \$3,184,853 (unusually large); cigars and cigarettes, \$1,164,369; leaf tobacco, \$1,033,900; hides and skins, \$311,183. The exports were classified as: Products of agriculture, 87 per cent.; manufactures, 7 per cent.; miscellaneous, 6 per cent.

The imports are chiefly manufactured articles, cotton goods usually forming one-third to nearly one-half of the total, and foodstuffs. Rice is the most important of the agricultural imports. The value of the chief imports in 1900 was: Cotton manufactures, \$8,727,777; rice, \$4,365,056; iron and steel articles, \$1,425,233; wheat flour, \$475,236; malt liquors and cider, \$1,113,684; mineral oils, \$374,717; silk manufactures, \$385,984; glass and glassware, \$395,620.

Manila hemp is almost the only article imported into the United States, the value of the fibre brought to this country in 1902 amounting to \$6,318,470.

Great Britain leads in the foreign trade with the Philippines, chiefly on account of its large purchases of Manila hemp and its surpassing sales of cotton cloth. The United States supplies more foodstuffs, excepting rice, which comes from Cochin-China, than any other country; and its sales of iron manufactures to the islands in 1902 amounted to \$957,342. In the same year the imported foodstuffs amounted to over \$14,000,000, or about two-fifths of the total imports.

TRANSPORTATION AND COMMUNICATION. The three leading ports of the islands are Manila, Cebu, and Iloilo. The situation of Manila (q.v.) gives it superior advantages in the domestic and foreign trade of the islands. Vessels, however, having a draught of more than sixteen feet are compelled to anchor two miles from the shore, and are dependent upon lighterage for loading and unloading cargoes. The Government intends to dredge an inshore harbor and protect it by breakwaters, so that the largest vessels may tie up at the docks. Cebu and Iloilo are the chief ports of the islands of Cebu and Panay, respectively, in the Visayan or great central group of islands between Luzon and Mindanao. There are also three ports of secondary importance: Aparri, on the north coast of Luzon, a large centre of tobacco shipments; Zamboanga, the leading port of Mindanao; and Jolo, the chief port of the Sulu Archipelago, in the south. Custom houses are maintained at these six ports, and

they are open to foreign trade. In addition to these ports there are a large number of local ports whose business is confined to the coastwise trade. Many of them are connected directly by small steam and sailing vessels with the ports engaged in the foreign trade. As the islands lack railroads and have very few roads of any description, they are dependent upon this large coasting trade for the distribution of their domestic commerce or for the dispatch to or receipt from foreign countries of articles in the foreign trade. Thus the leading ports are the forwarding and distributing points for the entire over-sea commerce. There are, for example, about thirty local ports at which the Manila hemp crop is collected for shipment to Manila, Iloilo, and Cebu, where it is transferred to vessels in the foreign trade. The freight rates on these coasting lines are high.

All the ports are reached from the interior by small rivers, or by bad cart roads or footpaths. These paths and trails extend from the ports in all directions, but are very inadequate, and commerce is hampered by the poor inland communica-

BANKING. There are three general banking corporations in the islands. The Banco Español-Filipino, at Manila, with a branch at Iloilo, monopolizes the bank-note circulation of the Philippines, amounting to 2,407,560 pesos (a peso = 50 cents). Its capital is 1,500,000 pesos. The Hong Kong and Shanghai Banking Corporation has branches at Manila and Iloilo, and the Chartered Bank of India, Australia, and China at Manila and Cebu. The aggregate liabilities of all these establishments on December 31, 1901, was 53,415,809 pesos, including deposits of 35,012,127 pesos. The Savings Bank and Pawn Shop of Manila, capitalized at 221,460 pesos, had in January, 1902, deposits amounting to 755,829 pesos and total resources of 1,096,597 pesos.

FINANCE. The central government is supported chiefly by import and export duties. The provincial and municipal governments derive their support from internal taxes. The revenues and expenditures in the archipelago from the date of the American occupation, August 20, 1898, to the end of the fiscal year, June 30, 1901, were as follows:

REVENUES	1899	1900	1901	Total
Customs.....	\$3,097,864	\$5,535,952	\$9,032,600	\$17,666,417
Postal.....	42,954	104,282	121,559	268,796
Internal.....	240,378	522,509	932,484	1,695,372
Miscellaneous.....	130,131	361,195	591,017	1,082,344
Total.....	\$3,511,327	\$6,523,938	\$10,677,660	\$20,712,929
EXPENDITURES				
Customs.....	\$29,177	\$134,685	\$280,815	\$444,678
Postal.....	30,410	89,149	147,031	266,591
Other expenditures.....	2,337,810	4,994,545	6,335,975	13,668,331
Total.....	\$2,397,397	\$5,218,379	\$6,763,821	\$14,379,600

tions. The only railroad extends from Manila north to Dagupan, on Lingayen Bay, 120 miles. It is estimated that the islands require at least 1000 miles of railroad as a factor in their development.

The islands are fairly well supplied, through the three leading ports, with transportation to foreign lands. They have direct steam communications with all the leading ports of South Asia, Australia, San Francisco, and Barcelona, Spain. A large amount of the freight, however, is transhipped at Hong Kong and other Asian points, where it meets the steamships of the regular lines in the European and American trade. In 1901, 789 British, German, Chinese, and other foreign vessels entered the ports of Manila, Iloilo, and Cebu. Very little of the trade even with the United States is carried in vessels flying the American flag. In 1902 about 94 per cent. of American sales to the Philippines and 99 per cent. of American purchases were carried in foreign bottoms. Since August, 1898, the Signal Corps of the United States Army has laid 1327 miles of cables between the islands and 5000 miles of permanent telegraph lines, so that most parts of the archipelago have now the means of rapid communication with one another. In 1903 direct electrical communication with the United States was opened by means of a Pacific cable between the east coast of Luzon and San Francisco by way of Guam, Midway Island, and Honolulu. Manila is also connected by cable with Hong Kong and the European system.

One-half of the internal revenue receipts in each province is turned over to the provincial treasury, and the remaining one-half to the municipalities of the province. A poll tax of \$1 Mexican is levied upon each male person between eighteen and fifty-five years of age, one-half being paid into the treasury of the town where he lives and the remainder into the provincial treasury. The municipal council may license saloons and other business requiring police supervision. An ad valorem land tax is collected for the benefit of the provincial and municipal governments, the provincial board levying one-eighth of 1 per cent. on the assessable land for roads and bridges, and may levy two-eighths more for general purposes. The municipal council is required to levy one-fourth of 1 per cent. for schools, and may levy one-fourth per cent. more for general purposes.

WEIGHTS, MEASURES, AND MONEY. The coinage in use comprises the Mexican silver dollar, and silver peso and fractional currency coined at the Manila mint, which was established in 1902. A large amount of pesos coined at the Philadelphia mint are sent to the Philippines in 1903. The Philippines silver coins are legal tender to the amount of \$10. Two pesos are exchanged for \$1 of United States money, and a ratio of 2 to 1 is maintained between Mexican dollars and United States gold. The metrical system of weights and measures is officially in use, but the Spanish denominations are also employed.

POPULATION. A census of the Philippines was

in progress when the insurrection began in 1896, and the American authorities found returns for over two-fifths of the population stored in Manila. The returns were made the basis for the estimate of the population in the twelfth census of the United States, where it is given as 6,961,339. A later Government estimate is 6,975,073, with 1137 towns, the population being divided among the island groups as follows:

GROUPS	Area sq. miles	Popula- tion	Towns
Luzon.....	44,235	3,727,488	570
Marinduque.....	681	48,000	6
Mindanao.....	46,721	495,659	130
Mindoro.....	4,108	106,200	19
Pulawan.....	5,037	52,350	14
Sulu Archipelago.....	1,029	22,630	14
Visayan Islands.....	25,302	2,497,908	381
Unassigned.....	740	24,838	3
Total.....	127,853	6,975,073	1,137

With the exception of Manila, the capital, which has a population of 350,000, there are no cities in the archipelago with more than 40,000 inhabitants, though there are about 30 towns with populations between 20,000 and 40,000. The most important of these are Albay, Batangas, Bauan, Laoag, Lipa, and Taal in Luzon, Cebu in the Visayas, and Zamboanga in Mindanao.

EDUCATION. There is considerable controversy as to the exact status and results of the system of education in operation before the American occupation. It is contended, on one hand, that the provisions for primary and secondary education were largely neglected, the tendency being to centre efforts upon the few who were sent to the college or university. It is accordingly asserted that comparatively few persons stood out prominently as educated Filipinos, while the great mass were either wholly illiterate or could barely read and write. Other authorities maintain that the Spanish system, considering the conditions which existed, achieved fair results. The report of the United States Commissioner of Education states that "the public elementary school system required by the Spanish law, whatever its defects, was widely diffused over the archipelago when the Americans arrived." In some places the average of those who could read and write was high, in others low—a diversity due to local conditions. Higher education was well provided for, and presented many admirable features. Since September 1, 1900, the civil administration has put in force an educational bill designed to provide wider instruction for the masses as well as the more prosperous class. The archipelago has been divided into seventeen educational divisions, with an American superintendent over each division. Up to 1903 about 1000 American teachers had been distributed for primary work in the towns; 200 American teachers for secondary work were also assigned to duty; 200 soldier-teachers were detailed from their regiments; and 3400 Filipino teachers were also appointed. Instruction in the English language was provided in 1500 schools, in which more than 200,000 children were enrolled. Night schools were opened in various parts of the archipelago, with an enrollment of about 25,000 pupils. Grammar and high schools are a part of the system. Permanent normal schools and vacation normal courses for the training of Filipino teach-

ers were organized. In 1903 plans were under discussion for increasing the number of trade schools and establishing schools of painting, sculpture, drawing, and music, and also a university at Manila. The aim of the common schools is in part to fit the Filipinos for practical work and to make a feature of agricultural and industrial training.

RELIGION. Under the treaty of peace of December 10, 1898, religious freedom is guaranteed to all. The people of the islands are largely Roman Catholic, though there are moon-worshippers, Mohammedans, Buddhists, etc. The Moros, living in the south, and the pagan wild tribes of the mountains, are the leading non-Christian classes. As shown by the Church registry in 1898, 6,559,998 Roman Catholics were distributed among 746 regular parishes, 105 mission parishes, and 116 missions. Most of the parishes are administered by Spanish friars of the Dominican, Franciscan, and Augustinian Orders, assisted by many native priests in the small parishes and missions, though since the American occupation several priests from the United States have been appointed to bishoprics. Controversy exists here also in regard to the attitude of the native population toward the friars. Some assert that they are obnoxious to a large part of the people, owing to the onerous contributions they are said to have levied for the support of the Church, and the large areas of tillable land they acquired, much of it, it is asserted, by dispossessing the owners on the pretext of exacting the Church's dues. The apologists of the friars, on the other hand, vigorously assert that their unpopularity is only with a faction of the natives, and springs largely from political motives. They call attention to the fact that a counter-movement of popular origin and considerable proportions has taken place in favor of the friars. When Spanish sovereignty ceased, many members of the Orders retired to Spain, and the policy of acquiring their lands and delegating their lands to other officials of the Church has been advocated in reports of the Philippine Commission.

GOVERNMENT. For a time after the transfer of the Philippines to American control, the islands were held under military government subject to the orders of the President of the United States. In January, 1899, a commission was appointed by the President to investigate conditions in the Philippines. (See below under HISTORY.) In February, 1900, the provisional government of the islands was intrusted to a new board of civil commissioners, five in number, at the head of which was Judge William H. Taft of Ohio. The other members were D. C. Worcester, Luke E. Wright, Henry C. Ide, and Bernard Moses. The commission reorganized the local civil governments and in January, 1901, established a municipal code for the government of cities other than Manila and tribal settlements. An electoral system making the qualifications for suffrage the ownership of property, payment of certain taxes, or a knowledge of English or Spanish was also created. A constitution for the government of the provinces enacted by the commission provided that their officials should be a governor elected by the municipalities subject to the approval of the commission, and a secretary, a treasurer, a commissioner of public works, and a public prosecutor, all appointed by

the commission. From time to time the commission instituted civil governments in the localities as circumstances required, until in 1903 more than 700 localities had local governments suited to their conditions. In June, 1901, the civil and military administration of the islands were separated by the appointment of Judge Taft as civil governor, thereby relieving the military governor of his civil duties in the pacified provinces. Shortly thereafter the commission was increased from 5 to 8 by the addition of three natives and was reorganized so as to place each member at the head of an administrative department. By an act of the commission dated June 11, 1901, the judicial system was reorganized. A Supreme Court was created to consist of seven justices, four American and three native; and sixteen Courts of First Instance, over which natives presided, were established. A considerable portion of the minor criminal jurisdiction was transferred to justices of the peace. A new code of civil procedure, authorizing the use of either English or Spanish in judicial proceedings, went into effect September 1, 1901. The city of Manila, the capital, is governed by a board of three commissioners somewhat after the manner in which the city of Washington is governed. In addition to the above measures the present constitution of government for the Philippines consists of the order of April 7, 1900, creating the Philippine Commission and defining its powers; that of June 21, 1901, creating the offices of Governor and Vice-Governor; an act of the Philippine Commission of September 6, 1901, organizing the departments of the interior, of commerce and police, of finance and justice, and of public instruction; and the important act of July 1, 1902, for the temporary government of the Philippines, which continued the government established under the above-mentioned orders and acts.

The act of July 1, 1902, defined the citizenship of the Philippines as including all the inhabitants of the islands who were citizens of Spain at the date of the ratification of the treaty with Spain, February 6, 1899, and declared that as such they should be entitled to the protection of the United States. The substance of the bill of rights of the Federal Constitution, except the right of maintaining a militia and the right of trial by jury, was extended to the Philippines. The act directed the President of the United States to have a census of the islands taken, and within two years thereafter, if peace prevailed in the islands, a legislative assembly should be called into existence. This body is to consist of two chambers, the Philippine Commission constituting the upper one, while the Lower House is to consist of from fifty to one hundred popularly elected delegates apportioned among the provinces on the basis of population, except that each province shall be entitled to at least one member. Persons qualified to vote for delegates include those who have held office under the Spanish régime or who own property of the value of \$250 or pay taxes amounting to \$15 or over, or who speak, read, and write Spanish or English. Two resident commissioners to the United States are to be chosen by the Legislature, and both commissioners and delegates are to be chosen biennially. The Legislature is to hold annual sessions; but if at any session the Legislature refuses to vote the necessary supplies for the support of the Government, the executive

may appropriate sums equal to the amount last appropriated.

The Supreme Court, the Courts of First Instance, and the Municipal Courts as established by order of the Philippine Commission June 11, 1901, are continued. The United States Supreme Court is given appellate jurisdiction over all judgments of the Philippine Supreme Court in cases involving more than \$25,000, or whenever the Constitution, the laws, or any right or title claimed under the authority of the United States is drawn in question. The Governor, Vice-Governor, members of the Philippine Commission, heads of executive departments, and the justices of the Insular Supreme Court are to be appointed by the President of the United States, with the advice and consent of the Senate. Congress reserves the power to annul all laws passed by the Philippine Legislature, and the Philippine Commission is directed to make annual reports of all receipts and expenditures to the Secretary of War. The Division of Insular Affairs instituted by the War Department is continued as the Bureau of Insular Affairs, and to this bureau are committed all matters pertaining to civil government in the insular possessions of the United States subject to the jurisdiction of the War Department. By a proclamation of July 4, 1902, the President of the United States declared the Philippine insurrection at an end everywhere except in the Moro territory and abolished the office of military governor, his authority in civil matters being superseded by that of the Philippine Commission.

ETHNOLOGY AND CUSTOMS. The inhabitants are unequally divided between blacks, browns, yellows, and whites, and there is also a slight representation of reds. The blacks comprise native tribes, with descendants of African negroes and Papuans introduced by Spaniards. The native blacks are of Negrito type, commonly called Aeta, from a principal tribe: they are dwarfish in stature, and dwell in remote parts of the archipelago. They are usually regarded as the aborigines, and as remnants of a pigmy race; some students consider them degraded Papuans. There are only twenty thousand of them. The brown race, either pure or mixed, constitutes nine-tenths of the population. A fraction are related to the Polynesians; yet the distinctness of this type is problematical, and the ethnologist finds his surest identities in the vast numbers of Malay peoples in the islands. The first immigrants were uncultured savages, whose descendants are now represented in the interior and the outskirts of the islands by living tribes. These were followed by incursions in historic times of Malay peoples having alphabets and a primitive culture. About B.C. 200 came the ancestors of many head-hunting tribes. The immigration of the Tagal, Visaya, Nicol, Ilocano, and other industrial tribes is assigned to A.D. 100-500. Third and last came the Islamic or Moro invasion, occurring in the fourteenth and fifteenth centuries of our era, and brought to an end by Spanish conquest in the sixteenth century. At present the brown Malay is mixing with white and yellow peoples. The yellow or Mongoloid type exists in the Philippines partly as pure-blooded Chinese, Japanese, Siamese, and Cambodians, but principally in mixtures of various sorts. The Chinese held sway in Luzon for centuries, and after their rule was thrown off trade continued between them and the natives.

It is improbable that these immigrations and blendings were numerous prior to the founding of Manila (1571) and the coming of Mexican and Peruvian silver in trade. So vigorous was the Chinese invasion afterwards that it threatened to overthrow the Spanish rule, while it resulted in the creation of a large mestizo population. The red or American race found its way into the islands on the Spanish ships sailing annually between Acapulco and Manila in the sixteenth, seventeenth, and eighteenth centuries. It was not so much a migration of peoples as of arts. There are evidences of small settlements of Mexican Indians in and about Luzon, and the civilized portions of the archipelago were enriched by maize, pineapples, tobacco, cacti, agaves, and the varied industries associated with them. The white race, in all its important elements, Hamitic, Semitic, and Aryan, was permanently mingled with the brown during the 250 years of Spanish domination. In Northern Luzon and in the mountainous and central portions of other islands the native blood has not been changed, but elsewhere the term 'pure-blood' has little meaning. This blending has been most rapid in the Tagal, Vicol, and Visaya tribes, which constitute the largest fraction of the population.

The Negritos are small in stature, with closely curled hair, yellow sclerotic coat, and white teeth, which they file. They are among the shortest of mankind, the average stature being 1.47 meters (58 inches). Their cranial capacity is 1100 to 1200 cubic centimeters, and their cranial index 85. The Malay or brown Filipinos are of dark chocolate color and average 1.50 meters (59 inches) in stature. Some are meagre in body, but most of them are sturdy.

Culture among the Filipinos extends from the low savagery of the Negrito tribes to a form of civilization fairly comparable with that of the countries on the continent adjacent. The industrial life of the Filipinos is partly agricultural and mechanical, partly maritime. The outrigger canoe is in evidence about all the islands. Clothing is little needed as a defense against cold, but the need of protection from the sun's rays and the rain has quickened inventive faculty in devising a style of headgear which combines the functions of hat and umbrella, varying from island to island, with a rain cloak, also varying in form and material. The dwellings are made of bamboo, rattan, and palm leaves. The original fire-making device was the fire-saw, consisting of a section of bamboo stem, notched and laid on the ground and rubbed crosswise by another piece in shape like a knife; the bamboo fire syringe is also common.

Industrially the Filipinos are in the Iron Age. They have little machinery. All their tools are of the rudest sort, and are either Malay or Spanish. Many of them, especially the Moro tribes, work cleverly in metals, but do little at mining or reduction of ores. Their most elaborate work is done on the blades of edged weapons. Pottery is made by the brown peoples for domestic purposes; working in hard woods is a fine art, and in textiles the Filipinos excel. They split the bamboo and rattan into delicate filaments for hats and screens; make thread, twine, and rope of the native hemp; ornament their clothing and furniture with delicate vines and grasses; and weave the finest of cloth from the fibre of the pineapple. These fabrics are plaited by hand or

wrought on looms, but it is difficult to tell which processes are Malayan and which came through Hispano-Mexican influences. The more advanced tribes rear a variety of small horse that is tough and serviceable; but the chief domestic animal is the carabao or water buffalo, which is largely used for turning water wheels for irrigation and as a draught-animal for plowing or hauling. Native transportation was originally by means of the buffalo, and rude water craft. Even before the coming of the Spaniards, the Chinese and the Japanese carried on a brisk trade with Manila and introduced their vehicles and money. During the 250 years of Spanish domination the 'groaning cart' and old-style water craft partly took the place of native devices.

The Negrito weapons of war and the chase are the bow with string of bamboo, and arrows with heads of wood or of iron procured in trade. The brown peoples have inherited from their ancestors edged weapons set on a hilt or a shaft. They carry also wooden shields, decorated with patterns cut in and rubbed with lime wash or mud. Firearms of many patterns are to be found. Fortification of the village is effected by path splinters and spiked pitfalls.

Fine art among the Filipinos had no separate existence, but the possession of a strong artistic sense is revealed by the taste displayed in their industries. Even the Negritos are not devoid of it. The dress of men and women; the metal working of the men, especially on their weapons; the exquisite textile work of the women—all show artistic instinct. Under the influence of Spanish teaching and the inspiration of European and Christian motifs, some of the native Filipinos have attained distinction in painting and literature.

The principal tribes and languages are: Abaca, Abra-Igorrote, Abulone, Adang, Aeta, Agutaino, Altaban, Apayao, Aripa, Atá, Bagobo, Baluga, Bangot, Barangan, Batak, Batane, Bicol, or Vicol, Bilane or Vilane, Bisaya or Visaya, Bouayanano, Buhano, Bulalacano, Bukidno, Bukil, Buquitnon, Cagayan, Calangan, Calamian, Calaua, Calinga, Caraga, Carolano, Catalangan, Catubangan, Cimarron, Coyuvo, Culáman, Dadayag, Dulangan, Dumagate, Durugmun, Eta, Gaddane, Gamungan, Guianga, Guimbahano, Guinaane, Halaya, Hiliguayna, Hilloona, Ibalone, Ibanag, Ibilao, Ifugao, Igorrote, Ilamut, Ilanos, Ilocanos, Ilongote, Iraya, Isinay, Ita, Itaa, Italone, Itanega, Itetapane, Kiangane, Lutanga, Lutayo, Maguindanao, Malauec, Malanao, Mamánua, Mandaya, Manguanga, Manguiane, Manobo, Mayoyao, Moro, Mundo, Nabayugan, Negrito, Palauan, Pampango, Pangasinan, Quiangan, Sámale, Sameaca, Sangley, Sanguile, Silipan, Subano, Tagabaloye, Tagabawa, Tagabelie, Tagacaolo, Tagala, Tagbanaua, Tandelano, Tinguan, Tinitian, Tino, Tiruray, Vico (Bicol), Vilane, Visaya (Bisaya), Zambale. Some of these names are also applied to localities, in which case the people may be called after the place, which is rare, or they may have given designation to the place, which is common. The tribes and languages are defined in their several places.

HISTORY.

In accordance with the terms of the Demarcation Bull of Pope Alexander VI. of May 4, 1493, the Spaniards were to make discoveries and to establish colonies beyond a meridian line in the Atlantic 100 leagues west of the Azores (later by

the Treaty of Tordesillas, June 7, 1494, 370 leagues west of the Cape Verde Islands), while the Portuguese were to confine their efforts to the field of discovery east of that line. In the race for the control of the spice trade of the East Indies the Portuguese came off victorious, for they reached the Moluccas or Spice Islands the year before Balboa discovered the Pacific Ocean, revealing that the Spaniards had found, not the Indies, but a great barrier continent that blocked the way thither.

The Moluccas lay so far to the east of India as to make it probable that if the demarcation line were extended round the earth they would be found to be in the Spanish half of the globe. It was to demonstrate this hypothesis and carry to completion the great design of Columbus to find a western route to the Spice Islands that Magellan undertook his voyage around America and across the Pacific. In March, 1521, he discovered a group of islands which he named after Saint Lazarus, whose festival was celebrated early in his stay among them. A few weeks later the heroic navigator lost his life in a skirmish with the natives. That he had achieved his project and proved that the Spice Islands lay within the Spanish half of the world was accepted by King Charles of Spain, but the impossibility of accurately determining longitude in those days, the difficulties of the voyage through the Straits of Magellan and across the Pacific, and financial necessities led him to relinquish all claims to sail or trade west of a new demarcation line, in the Antipodes, 297 leagues east of the Moluccas. (Treaty of Saragossa, 1529.) This really surrendered all rights to the newly discovered Islands of Saint Lazarus, which were slightly to the west of the Moluccas. The conquest of Mexico and the establishment there of the prosperous Viceroyalty of New Spain removed the difficulties presented by the navigation of the Straits of Magellan, and, in contravention of the provisions of the treaty, an expedition was dispatched to the islands in 1542 under the command of Villalobos. This expedition had no permanent result beyond giving to the group the name of 'Islas Felipinas,' in honor of the Prince, later King Philip II. The permanent conquest of the islands was achieved under Legaspi at the head of an expedition fitted out in Mexico. Legaspi arrived at Cebú in April, 1565. It was three years before his first reinforcements came, and five years before the conquest of Luzon was undertaken. In June, 1571, the city of Manila was founded, and this became the seat of the Spanish power. Within the next year great progress was made and at the time of Legaspi's death in August, 1572, the Spanish authority was securely planted in the islands and the conversion of the natives considerably advanced. Legaspi's force was small and the conquest was accompanied by relatively little bloodshed. The lack of social and political cohesion among the natives, the weakness of their religious beliefs, and the rivalries and hostility of the local chieftains opened the way for a patient and tactful prosecution of the policy of divide and rule; one chief after another was won over to the Spaniards, the picturesque ceremonials of the Church appealed to the artistic sense of the people, and the simple clan-like social organization was skillfully utilized by the Spaniards as the basis of their rule. Lying on the extreme verge of the vast empire of Spain, the islands

were commonly known as the Western Islands (Islas del Poniente), and until December 31, 1844, they were reckoned, so far as the calendar was concerned, in the Western Hemisphere, Manila time being about sixteen hours slower than Madrid time. The Portuguese protested against this invasion of their East Indian realm, but the conquest of Portugal by Spain in 1580 settled the question before there had been any serious collision. More formidable than the hostility of Portugal or the resistance of the natives were the incursions of Chinese pirates and later the attacks by the Dutch, who during their great contest with Spain made their way to the Indian seas and took possession of the Spice Islands.

The dominating impulse in this remote extension of Spanish power had been religious rather than commercial. The new conquest was to be an outpost of Christianity facing the great Asiatic heathen world. From it as a base the missionaries could prosecute their labors effectively in China and Japan. Religious purposes and interests continued to dominate the life of the islands for over three centuries. They never were in the true sense of the term a Spanish colony, but a great mission like the more familiar Jesuit missions in Paraguay and California. It is as a mission that the history of Spanish rule should be studied and its results estimated. To convert the natives, to collect them in villages where they would live under the oversight of the pastor with the faithful obedience of the flock to the shepherd and prepare themselves for salvation, was the simple ideal of the mission. That it was in a large measure achieved is the very general testimony of fairly dispassionate observers. The Christian population steadily increased, and the requirements of religion, while rigorously enforced, were not more burdensome than in Europe. There was little real oppression and hardly any exploitation of the people. Plantation slavery, the dark page in West Indian colonization, never existed. Schools were provided in the pueblos and in the larger towns hospitals and colleges; the native languages were given literary form, grammars and dictionaries were compiled and translations made of the simpler literature of the devotional life. The Christian population of the islands formed a unique community, the only large body of Asiatics permanently converted to Christianity in modern times. In its general framework the administration of the islands as a Spanish dependency was modeled on the system introduced into America, which in turn was an adaptation of that existing in the provinces of Spain. At the head was the Governor with viceregal powers, having by his side the Audiencia or Supreme Court. This body served not only as the highest court of appeal, but also as a check upon the arbitrary authority of the Governor. Another important restraint upon that official was the *residencia*, or obligation to stand ready to answer all charges of misbehavior which should be preferred during a period of six months, after the termination of his tenure of office. The heads of the provincial administration were the *Alcaldes Mayores*, whose functions were both executive and judicial. In his judicial duties the Alcalde Mayor was assisted by an assessor and a notary. The administrative division below the province was the pueblo or village, which was ruled by the Petty Governor, who was origi-

nally elected by the general suffrage of the married inhabitants of the pueblo, but in later years was chosen by a small body of thirteen electors. Within the pueblos the population was subdivided into little clan-like groups of forty or fifty families called *barangays*, a survival of the earlier native organization, each under a *barangay* headman (*cabeza de barangay*). Each family was assessed a tribute of 10 reals, about \$1.25, and the headmen were responsible for its collection. The petty governors and headmen of *barangays* were Filipinos; the higher administrative officers were Spaniards. The inhabitants of these pueblos were all natives. No Spaniards were allowed to live in these mission villages except the friars, who exercised there the firm but ordinarily gentle sway of the parent or schoolmaster. In the few Spanish towns there existed the ordinary municipal organizations that prevailed in Spanish America. There was the town corporation 'el Cabildo' (chapter), consisting of two *alcaldes* (justices), eight *regidores* (aldermen), a registrar, and a constable. The members of the Cabildo held office permanently. Membership could be bought and sold or inherited.

At the head of the ecclesiastical administration stood the Archbishop of Manila, the Bishops of Cebú, Segovia, and Cáceres, and the Provincials of the four great Orders of friars (the Dominicans, Augustinians, Franciscans, and barefooted Franciscans), and of the Jesuits. The members of these Orders (the regular clergy) greatly preponderated in numbers and influence over the secular clergy, who were mostly natives.

The economic development of the islands was rendered impossible by the manufacturers in Spain, who demanded protection against Asiatic competition in the markets of Mexico and Peru, and secured the restriction of the imports from the Philippines to the cargo of an annual ship. Under this handicap the islands never were a self-supporting, much less an income-yielding, dependency. They were always a burden upon the treasury of New Spain. Their principal trade was with China and was in the hands of the Chinese. The vast majority of the pueblos were simple self-supporting communities of farmers and small artisans.

Secluded from the outside world, the domestic history of the Philippines is distinctively parochial in its character. There is little progressive political or economic evolution from generation to generation. Progress is manifested by the extension of the missions and the amelioration of the life of the natives. Much of the internal history is made up of the various conflicts between the clergy and the political administration or between the Archbishop and the friars. The chief incidents in external history are the volcanic eruptions, the incursions of the Chinese or Moro pirates, the attacks of the Dutch, etc. The events of the great Seven Years' War rudely interrupted this placid life. Spain, drawn into the maelstrom of this conflict in the vain hope of recovering Gibraltar, lost the Floridas and saw Havana and Manila fall before English fleets. The preliminaries of peace, however, had been agreed upon before the news reached England of the capture of Manila, and the conquest was therefore relinquished to Spain. The reforming Government of Charles III. exerted its activities even to the remote Philippines. The Royal Philippine Company was chartered to carry on direct

trade between Spain and the islands (1785). Three years earlier the enterprising Governor-General Basco y Vargas, to make the colony self-supporting, introduced the Government tobacco monopoly (1782), by which lands suitable for growing tobacco were arbitrarily pressed into that service and the cultivators compelled by forced labor to produce stipulated amounts to be sold to the Government at fixed prices. This system of compulsory labor was practically the first attempt really to exploit the resources of the islands, and during the following century was fruitful in abuses and of the seeds of revolt. It was abolished in 1882. In this connection should be mentioned the *polos y servicios*, forty days' required labor on the roads, bridges, public buildings, etc., which was exacted of the natives in addition to their tribute. These requirements for public service could be canceled for from one to three dollars. The official class men were exempt from this burden.

The Mexican Revolution severed the ancient connection of New Spain with the 'Western Islands,' and the Spanish Constitution of 1812, which embodied the principles of the French Revolution, and which put all parts of the Spanish Empire on an equality and admitted the Philippines to representation in the Cortes, led the natives to believe that now they would be exempt from tribute and *polos y servicios*. Consequently, when the news came that Ferdinand VII. in 1814 had abolished the Constitution of 1812, the Ilocanos rose in rebellion. Henceforward the agitations of home politics and the example of the Spanish-American States steadily undermined the old-time stability of conditions in the Philippines. The mission system could not be maintained in its integrity. The number of Spaniards in the islands increased, the spirit of colonial exploitation grew, the monastic Orders which combined the functions of landlords and spiritual guides were more and more pervaded with the mercantile spirit. Nor did their predominant influence in the government of the islands at all diminish in an age progressively hostile to clerical control. The opening of the Suez Canal brought the Philippines relatively near to Europe and more than ever exposed them to the contending forces of modern thought. Promising young Filipinos completed their education in Europe. By a few weeks' voyage they found themselves in many respects transported from the sixteenth century to the nineteenth. That they should contentedly return to the earlier age was impossible. The Spaniards did not weather the transition. The final collapse began with the insurrection of 1896, which was primarily an agrarian revolt aimed at the expulsion of the Orders from their estates and the islands.

It seems to be agreed that the establishment of Masonic lodges in the islands and the admission to them later of prominent Filipinos and Mestizos of anti-clerical or liberal sentiments offered a nucleus for agitation, facilitated united action, and led immediately to the formation of the patriotic Asociación Hispano-Filipina, the Liga Filipina, and the revolutionary society, "el Katipunan." The first Masonic lodges were founded about 1860, but it was over a quarter of a century before they became active centres of anti-clerical agitation. The Asociación Hispano-Filipina was devoted to promoting Filipino national aspirations through literary channels, and established an organ, *La Solidaridad*, in Barcelona.

The Liga Filipina was founded by Dr. José Rizal (q.v.) to work for the expulsion of the friars and to secure the same political concessions for the islands that had been granted to Cuba, a larger recognition of the natives in the appointments to civil offices, and freedom of the press and of association. More radical than these was the Katipunan, which was established in 1892 to secure independence by open revolt, and began by wholesale assassinations of Spanish officials and friars. The existence of an elaborate plot was revealed by a native, August 19, 1896, and on the 25th the mask was entirely thrown off. The garrison of Manila consisted of only 300 Spanish regulars and about 1200 native soldiers. The total number of Spanish soldiers in the islands was under 2000. The authorities could act only on the defensive until October, when reinforcements began to arrive from Spain. On the other hand, the insurrectionists were hampered by a great lack of arms and ammunition. The insurrection centred in the province of Cavité, which was under the control of the rebels until their power was broken in the spring of 1897 by the vigorous campaign of General Lachambre. Its leaders were Andrés Bonifacio, the head of the Katipunan, and Emilio Aguinaldo (q.v.).

After organized resistance had been shattered, it seemed wise to the Governor-General, Primo de Rivera, to attempt to secure peace by obtaining the withdrawal of the native leaders from the islands. In accordance with the Treaty of Biacnabató, Aguinaldo and some of the other generals withdrew to Hong Kong. No properly authenticated text of this treaty has ever been published. That made public by Aguinaldo is substantially identical with the demands which he made, and which it would appear were not acceded to by Primo de Rivera. Aguinaldo demanded \$3,000,000, the expulsion of the friars, the representation of the Philippines in the Cortes, equality of Filipino and Spaniard in the administration of justice, the participation of Filipinos in the higher administrative offices, a readjustment of the property of the parishes and of the taxes in favor of the natives, the proclamation of the individual rights of the natives, and liberty of association and of the press. Aguinaldo has asserted that the suppression of the religious Orders and the establishment of administrative autonomy were agreed upon, although not put down in writing, Governor-General Primo de Rivera giving his word of honor that the agreement would be fulfilled. Primo de Rivera, on the other hand, maintained that nothing but money and personal security were promised to the leaders. The treaty was signed December 17, 1897. Only the first installment (\$400,000) of the sum of \$800,000 finally fixed was ever paid, and, on the other hand, the insurrection was quieted only temporarily. In March, 1898, a new rising in the provinces north of Manila took place and early in April there was an outbreak in the island of Cebu. On March 24th the Seventy-fourth Regiment of native soldiers deserted to the insurgents, who now vastly outnumbered the Spanish forces, but were greatly hampered by the lack of arms.

The day that war began between Spain and the United States, Aguinaldo appeared in Singapore, and on April 24, 1898, United States Consul-General Pratt had a conference with him in reference to cooperating with Commodore Dewey. Of the exact nature of the understanding the same

uncertainty exists as in the case of the Treaty of Biacnabató. What is certain is that Commodore Dewey arranged for Aguinaldo to follow him to Manila and that Aguinaldo expected the United States to pursue in the Philippines the policy proposed for Cuba, the policy of common action with the insurgents against Spain for their liberation from her rule. What is probable is that Consul Pratt at Singapore, and Consul Wildman at Hong Kong, and Commodore Dewey as well, had similar expectations. Later they all equally disclaimed having bound the United States in any way. On May 1st the Spanish fleet in the Bay of Manila was annihilated by the Asiatic Squadron under Commodore Dewey. Aguinaldo arrived at Cavité on May 19th, in the American dispatch boat *McCulloch*. He had an interview with Dewey, who supplied him with arms for the insurgents, who flocked to his standard. In the weeks that elapsed until the arrival of General Merritt late in July, Aguinaldo secured control of the Province of Cavité and thoroughly invested Manila by land. His capture of Spanish garrisons was not only sanctioned, but assisted by Dewey, and had it not been for the native forces the capture of Manila would have been a far more arduous undertaking for the Americans and the Spanish forces might have eluded them by retiring into the interior. As it was, the condition of the Spaniards was hopeless, and on August 11th the arrangement was effected, through the Belgian Consul André, by which the American ships should refrain from firing on the walled city of Manila and the Manila forts from firing on the ships, while on shore there should be only a brief show of resistance to enable the Spanish general to save honor at least. The American soldiers were in ignorance of this arrangement, and through an accident there was more bloodshed than was intended at the taking of the city (August 13th). To the onlooking foreigners in the harbor the transaction seemed like a travesty of war. The fall of Manila marked the complete collapse of the Spanish power in the islands. The Americans held the capital and controlled the harbor; and Aguinaldo and the insurgents rapidly extended their control over the various provinces.

In the meantime (almost exactly coincident with the capture of Manila) came the signing at Washington of the peace protocol (August 12th), providing that the United States should occupy and hold the city, bay, and harbor of Manila, pending the conclusion of a treaty of peace, which should determine the control, disposition, and government of the Philippines. On October 31st, after the Peace Commission had been at work in Paris for a month, the Spanish plenipotentiaries were painfully surprised by a demand for the cession of the whole group. It was nearly a month before Spain yielded to the inevitable. In the treaty as signed December 10, 1898, Spain ceded the whole group and the United States agreed to pay Spain \$20,000,000, give Spanish ships and merchandise admission to the islands on the same terms accorded to American ships and goods for a period of ten years, and to transport to Spain the Spanish soldiers captured at the surrender of Manila. The treaty was submitted to the Senate of the United States January 4, 1899, and it was ratified February 6th, by only three votes more than the necessary two-thirds majority (57 to 27).

In the meantime, before the protocol of peace, Aguinaldo had organized a government (June 12, 1898), and in the provisional constitution promulgated June 23d he announced the independence of the islands as the chief object of the Revolutionary Government. On August 6th Aguinaldo appealed to the powers of the world for recognition of his forces as belligerents and of the independence of the Philippines, asserting that the Revolutionary Government was predominant in fifteen provinces. These provinces comprised the central part of Luzon and the majority of the inhabitants. During the following months the Americans held Manila and the native forces the rest of the island. The hopes of independence under American protection, which had been based upon the declared attitude of the United States toward Cuba and the friendly cooperation of Admiral Dewey and General Anderson, were rudely shaken by the proposed annexation of the islands to the United States, and relations became greatly strained in consequence of President McKinley's proclamation of December 21st that the islands were ceded to the United States and that military rule was to be extended over them as rapidly as possible. The tension proved too great to last, and on the night of February 4, 1899, hostilities broke out at Manila. The news of this battle, reported as an attack by the Filipinos on the Americans, no doubt contributed to the ratification of the peace treaty two days later.

The first intimations that the islands might be annexed called forth opposition in the United States, which was increased by the open declaration of that policy by the Government and greatly intensified by the outbreak of war between the American army and the Filipino republic. This opposition characterized the acquisition of the islands as the beginning of imperialism, as at variance with the traditional policy of the United States toward peoples struggling for independence, as being identical in its purposes with the projects of Napoleon III. in Mexico, as irreconcilable with the principles of the Declaration of Independence and the spirit of the Constitution, and as inevitably involving unknown expense and bloodshed. It was urged that our policy should have been one of conciliation and substantially identical with that pursued in Cuba, that the Filipinos were as capable of self-government as the South Americans, in whose behalf the Monroe Doctrine was first promulgated, or as the adherents of Juarez in Mexico, who were supported by the United States against Maximilian, and that a protectorate by the United States would have been acceptable to the Filipinos. On the other side, the acquisition of the islands by the United States was declared the only possible solution that would save them from anarchy or from falling into the hands of some European power, and that it was the duty of the United States to accept the burden. Others felt strongly the appeal of the great natural resources of the archipelago, almost undeveloped by Spain, and the immense strategic importance of holding them in view of the future Eastern Asiatic questions.

The discussion of the points of view and the policy of the Government were hampered by great lack of knowledge of the situation. To meet in part this difficulty, President McKinley appointed, in January, 1899, a commission, consisting of President Schurman of Cornell Uni-

versity, Admiral Dewey, Gen. E. S. Otis, the Hon. Charles Denby, and Prof. D. C. Worcester, to investigate conditions in the islands and to labor for the acceptance of American rule by the natives. In March, 1899, the Commission began its work. On April 5th it issued a proclamation to the people of the islands, explaining the purpose of their mission and the intentions of the American Government. The efforts of the Commission were devoted particularly to conciliating prominent Filipinos, and to building up a party favorable to American rule. To do this concurrently with the vigorous prosecution of the war was uphill work. In May they had a conference with some representatives of Aguinaldo, but it came to nothing.

The operations of the American army disorganized the republic and the national movement became embodied in the leadership of Aguinaldo. During the first nine months of the war disappointingly little headway was made by the Americans. The great majority of the engagements were within a radius of fifty miles of Manila. The military authorities exercised a rigid censorship over the press dispatches, so that it was practically impossible for the general public to know the real conditions. In the fall and winter of 1899 there was greater progress. Most of the country, from Manila to Dagupan, came under American control, and the native army was driven to the mountains. The principal events in 1900 and 1901 were in connection with the process of establishing civil government in the islands for which see above under *Government*.

On March 23, 1901, Aguinaldo was captured, and on July 4th military government was superseded by civil government in the pacified districts. By act of Congress, approved July 1, 1902, civil government was established throughout the islands. Up to the establishment of civil rule in July, 1902, the total number of troops sent to the islands amounted to 4135 officers and 123,903 men. The cost of the war to the United States was over \$170,000,000.

BIBLIOGRAPHY. The numerous works on the Philippines fall naturally into two groups, those describing the condition of the islands under Spanish rule, and those dealing with the new order of things brought about by American supremacy. To the first group belong the following: Mallat, *Les Philippines* (Paris, 1846), perhaps the best single work; Jagor, *Reisen in den Philippinen* (Berlin, 1873); Sansienco, *El progreso de Filipinas. Estudios económicos, administrativos y políticos. Parte económica* (Madrid, 1881); Jordana y Morera, *Bosquejo geográfico e histórico-natural del archipiélago filipino* (ib., 1885); Montero y Vidal, *El archipiélago filipino y las islas Marianas, Carolinas y Palaos* (ib., 1886); id., *Historia general de Filipinas* (Madrid, 1887-1895), perhaps the best general history; Meyer and Schadenberg, *Die Philippinen* (Dresden, 1890-1892); Zuñiga, *Estadismo de las islas Filipinas*, ed. by Retana (Madrid, 1893), which has a bibliography; Sastrón, *Colonización de Filipinas* (Malabón, 1897). The second group includes: Foreman, *The Philippine Islands* (2d ed., London, 1899), which gives an immense amount of information, and is the basis of several other works; Young-husband, *The Philippines and Round About* (New York, 1899), a general résumé of the history and political conditions; Lala, *The Philippine Islands*

(New York, 1899), which gives the point of view of a progressive Filipino; Sawyer, *The Inhabitants of the Philippines* (London, 1900), a historical study of the elements that make up the population of the islands; Buel, Wright, etc., *Our Late Wars: Spain and Our New Possessions* (Washington, 1900); Robinson, *The Philippines: The War and the People* (New York, 1901); Schurman, *Philippine Affairs: A Retrospect and an Outlook* (New York, 1902), an account of the proceedings of the first American Commission; U. S. *Philippine Commission, Report to the President* (4 vols., Washington, 1900-1901); Blair and Robertson, *Philippine Islands, 1493-1803*, an exhaustive work on the early history, compiled from original documents, to be in 55 vols. (Cleveland, Ohio, 1903 et seq.). On special periods of the history, consult for conquest and first half century, A. de Morga, *The Philippine Islands*, trans., Hakluyt Society (London, 1868); for the eighteenth century, Le Gentil, *Voyage dans les mers de l'Inde* (Paris, 1781). For the first half of the nineteenth century, Comyn, *Memoria sobre el estado de Filipinas* (Madrid, 1820; Manila, 1877; trans. by Walton, London, 1821); Sinibaldo de Mas, *Informe sobre el Estado de las Islas Filipinas en 1812* (Madrid, 1842); Buzeta and Bravo, *Diccionario geográfico, estadístico, histórico de las Islas Filipinas* (Madrid, 1850); Bowring, *A Visit to the Philippine Islands* (London, 1859). The novels of José Rizal, the Filipino patriot, illustrate the social conditions prior to 1896. *Noli me Tangere* (Berlin, 1856) appears in English somewhat condensed in two editions—*An Eagle Flight* (New York, 1901), and *Friars and Filipinos*, trans. by Gannett (New York, 1902). It was translated into French as *Au pays des Moines* (Paris, 1899). Other works on miscellaneous subjects are: Semper, *Reisen im Archipel der Philippinen* (Leipzig, 1868-1901); Blumentritt, "Versuch einer Ethnographie der Philippinen," in *Petermann's Mitteilungen, Ergänzungsheft* 67 (Gotha, 1882); Worcester, *The Philippine Islands and Their People* (New York, 1898); Stevens, *Yesterdays in the Philippines* (London 1890); Tornow, "The Economic Condition of the Philippines," in *National Geographic Magazine*, vol. x. (Washington, 1899); Morris, *Our Island Empire* (Philadelphia, 1899); Millet, *The Expedition to the Philippines* (New York, 1899); Sonnichsen, *Ten Months a Captive Among Filipinos* (New York, 1901); and for bibliography, Josephson, "Bibliographies of the Philippine Islands," *Bulletin of Bibliography*, vol. ii. (Boston, 1899). For the ethnology, consult: Blumentritt, "List of the Native Tribes of the Philippines, etc.," in *Smithsonian Report* (Washington, 1901); Meyer, "Die Philippinen," in *Ethnographisches Museum*, vol. viii. (Dresden, 1890); Brinton, "The Peoples of the Philippines," *American Anthropologist*, vol. xi. (New York, 1898), which has a bibliography; Meyer and Schadenburg, *Album von Philippinen-Typen* (Dresden, 1891); id., "Die Philippinen," and id., "Negritos," *Königlich-Ethnographisches Museum zu Dresden* (Dresden, 1893).

PHILIPPINE LANGUAGES. The number of languages spoken in the Philippine Islands is variously estimated as from about 25 to over 50. These languages may be considered under two heads: (1) the languages of the Negritos, probably the remnants of the aboriginal population, who live in scattered tribes in the interior of

most of the large islands; (2) the languages of the various tribes of Malay race which constitute the bulk of the population (Christian, Mohammedan, and pagan).

About the idioms of the Negritos very little is known, but they are apparently similar to the Malay dialects. This similarity, however, is perhaps to be explained as due to the influence of the languages of the surrounding Malay tribes, especially as, according to Spanish authorities, the Negrito languages are of monosyllabic structure, and entirely different from the languages of the Malays.

The idioms of the Malay tribes form a closely connected group of tongues which constitute a branch of the Malayo-Polynesian family of speech. The principal languages of the Christian tribes are: Batan (Batan and Babuyan islands, north of Luzon), Ibanag (North Luzon), Ilocan (North-west Luzon), Pampango (Central Luzon), Pangasinan (West Luzon), Tino (language of the Zambals, West Luzon), Tagalog (Manila, Middle Luzon, coast of Mindoro), Bikol (South Luzon), Bisayan (spoken in various dialects in the Bisayan Islands, and North and East Mindanao). The principal languages of the Mohammedan tribes are the Sulu of the Sulu subarchipelago and the coasts of Palawan, and the Magindanao of Southwest Mindanao. The idioms of the pagan tribes which inhabit the mountain districts of Northern Luzon, a large part of Mindanao, and the interior of Mindoro, Palawan, and the western Bisayan Islands, are very numerous, but little known. Among the best known are the Gaddan and Isinay of Luzon, and the Tiruray and Bagobo of Mindanao. A number of the Philippine languages, such as Tagalog and Bisayan, have reached a high state of development, and are well suited for literary use.

The vocabularies of the Philippine languages contain several foreign elements. In common with other languages of the Malay branch of the Malayo-Polynesian family, many of the Philippine dialects have borrowed a number of Sanskrit words. The languages of the Christian tribes also contain a number of Spanish words, those of the Mohammedan tribes a number of Arabic words.

The alphabets in which the native languages were or are written are also due to these foreign influences. The native alphabets, which are no longer used except by the Mangians of Mindoro and the Tagbanuas of Palawan, were probably derived from India. The Mohammedan tribes of the south now use the Arabic alphabet with some additional signs, while the languages of the Christian tribes are written in the Roman alphabet conformed to the peculiarities of Spanish orthography.

The sounds of the Philippine languages are in the main similar to those of English. All the languages, however, possess a peculiar guttural-nasal sound (written *ng*) distinct from the ordinary guttural-nasal *ng* as in Eng. *sing*. In some of the languages, as in Tagalog and Bisayan, there is a peculiar *r*-sound, due to a phonetic modification of *d*.

The roots of these languages are for the most part dissyllabic. They may be used uncoupled as nouns or adverbs, but only rarely as verbs. Derivation is accomplished by means of a great variety of particles, which are usually employed as prefixes, though there are a few suffixes and infixes. So prominent a characteristic is this use

of particles, that these dialects are sometimes spoken of as 'Particular' languages. Reduplication is very common in the formative processes of both noun and verb. There is no distinction of gender, nor is there, generally speaking, any inflection to denote person, number, or case in verbs or nouns. Only in certain pronouns is there found a species of inflection to indicate case. Verbs are practically always derivative, the particles employed being of two kinds: (1) special verbal particles, which give the root a simple verbal meaning or the signification of causative, intensive, etc., each particle generally having two slightly different forms, one used with active and the other with passive verbs; (2) the common or essential passive particles, which are an essential part of practically all passive forms. The combination of root and verbal particle is often modified to indicate differences in mood and tense.

The most salient syntactical characteristics of these languages are: (1) the use of certain particles, so-called ligatures, to connect two or more words which stand to each other in the relation of modifier and modified; such as adjective and noun, noun or pronoun and appositive, adjective or verb and adverb; (2) the prevailing use of a passive construction, the verb standing in the active only when the object of the action is something indefinite or when the agent is specially emphasized; (3) a paucity of simple prepositions, one or two being used to express the greatest variety of relations.

The following is a brief grammatical sketch of Tagalog, the most important of the Philippine languages:

The articles are simply definite, personal, and inclusive (used with names of persons), as *ang táwo*, 'the man,' *si Pedro*, 'Peter,' *siná Pedro*, 'Peter and his companions.' They have three case forms, nominative, genitive, and oblique. The plural of nouns is expressed by preceding *manḡá*, e.g. *manḡá táwo*, 'men'; case, by the case forms of the article or pronominal adjectives.

Adjectives are usually made by prefixing *ma* to a root, as *ma-búti*, 'good'; plural *mabubúti* or *manḡá mabúti*.

The pronouns have usually three case forms. Among them are to be noted *tayó*, 'we (including you),' *kami*, 'we (not you),' *kitá*, 'we two.'

The ideas of 'being' and 'having' are expressed by independent particles.

Verbs are divided into seventeen classes according to the special verbal particles. Four stems are distinguished, imperative-infinitive, future, preterite, and present. One class has no special particle in the passive, the active particle being *um*; in the others the special particle has generally initial *p* in the passive, which becomes *m* in the imperative-infinitive and future active, and *n* in the preterite and present active, as *pag*, *mag*, *nag*, etc. The present and future are characterized by reduplication. The common passive particles are *in*, *i*, *an*.

Practically the only simple prepositions are *sa* and, with names of persons, *kay* and *kaná*, 'to,' 'for,' 'from,' 'in,' etc. Adverbs and conjunctions are numerous and important.

The ligatures are, *-ng* after a vowel or *n*, *na* after other consonants, as *ang malakás na táwo*, 'the strong man,' *lubhá-ng mabúti*, 'very good.'

The construction of verbs is very similar to that of nouns. When the subject precedes, it is

connected with its verb by the particle *ay*, 'to be.' The direct object of the active and the agent of the passive stand in the genitive, other nominal adjuncts in the oblique case. Any verbal form may take the article *ang*. The character of the subject determines the verbal form to be used in a sentence. In general, if the subject is the agent of an action, the verb stands in the active, otherwise in the passive. The *in*-passive is used in general when the subject is the object of an action, the *i*-passive when it is the object of an action away from the agent, or the cause of an action, the *an*-passive when it is the place of an action.

The Philippine languages possess little literature. The old native manuscripts inscribed on leaves or strips of cane have been lost. At the present day the scanty native literature may be grouped under three heads: (1) religious writings; (2) native poetry; (3) native newspapers and newspaper articles.

Consult: Totanes, *Arte de la lengua Tagala* (2d ed., Binondo, 1865); Campomanes, *Lecciones de gramática Hispano-Tagala* (5th ed., Manila, 1894); Noceda, *Vocabulario de la lengua Tagala* (2d ed., ib., 1860); Zueco, *Metodo del Dr. Ollendorff . . . adaptado al Bisaya* (ib., 1871); Bermejo, *Arte compendiado de la lengua Cebuana* (Bisayan) (2d ed., Tambobong, 1894); Lozano, *Cursos de lengua Panayana* (Bisayan) (Manila, 1876); Mentrída-Aparicio, *Arte de la lengua Bisaya-Iiligayna* (Tambobong, 1894); Figueroa, *Arte del idioma Visaya de Samar y Leite* (2d ed., Binondo, 1872); Encarnacion, *Diccionario Bisaya-Español* (3d ed., Manila, 1885); Naves, *Gramática Hispano-Ilocana* (2d ed., Tambobong, 1892); Agustín, *Vocabulario Iloco-Español* (2d ed., Manila, 1888); De Cuevas, *Arte nueva de la lengua Ybanág* (2d ed., ib., 1854); Bugarín, *Diccionario Ibanag-Español* (ib., 1854); Bergaño, *Arte de la lengua Pampanga* (2d ed., Sampaloc, 1736); id., *Vocabulario de la lengua Pampanga* (2d ed., Manila, 1860); Pellicer, *Arte de la lengua Pangasinana* (2d ed., ib., 1862); Cosgaya, *Diccionario Pangasinán-Español* (ib., 1865); San Agustín-Crespo, *Arte de la lengua Bicol* (ib., 1879); Cowie, *English-Sulu-Malay Vocabulary* (London, 1893); Juanmartí, *Gramática de la lengua de Maguindanao* (Manila, 1892); id., *Diccionario Moro-Maguindanao-Español* (ib., 1892).

PHILIPPONS. A Russian sect, a branch of the Raskolniki (q.v.), who emigrated to Lithuania and East Prussia at the beginning of the eighteenth century. They take their name from their leader, Philip Pustosviät. They are described as peaceable and orderly, skilled in agriculture, thrifty, and industrious. They refuse to take oaths or perform military service, and set a high value upon suffering and death for conscience' sake. Priestly duties, such as leading in worship, baptism, and absolution, are performed by the oldest of the community. They do not observe the Lord's Supper, and have no confirmation or religious marriage ceremony. Their religious services consist in singing psalms, and reading the Gospels.

PHILIPPOPOLIS (Bulg. *Plovdiv*, Turk. *Filibch*). The largest city of Bulgaria next to Sofia, and formerly the capital of Eastern Rumelia. It is situated in a wide, fertile plain at the head of navigation on the Maritza

River, on the railroad between Constantinople and Sofia, and 80 miles southeast of the latter city (Map: Balkan Peninsula, E 3). Most of the houses are of wood, but the city has in recent years been much enlarged and beautified by the laying out of new streets and public parks, such as the beautiful Exhibition Park, laid out in 1892, and the growing up of fine residential suburbs containing the villas of wealthy Greeks and Bulgarians. The city is the seat of a Greek archbishop, and has a new Greek cathedral, besides a number of other Christian churches and many mosques. There are also a college and a national library. Philippopolis is the chief commercial centre of Southern Bulgaria, and has an active trade in the products of its manufactures, such as silk and cotton fabrics and attar of roses, as well as in rice, grain, tobacco, and hides. Population, in 1888, 33,032; in 1900, 42,849, of whom nearly half are Bulgarians, the remainder being mostly Turks and Greeks. Philippopolis was an important Thracian city in ancient times. It was almost wholly destroyed by an earthquake in 1818, and again by fire in 1846; but it recovered rapidly, owing to its excellent trade facilities.

PHILIPPOTEAU, fé'lô'pôtô', FÉLIX (1815-84). A French battle painter. He was born in Paris, and was a pupil of Léon Cogniet. His thorough knowledge of military details enabled him to depict the turmoil of battle with great historical truth, as may be judged by the following more important productions from his brush: "Louis XV. Inspecting the Battlefield of Fontenoy" (1840, Luxembourg Museum); "Battle of Balaklava" (1859); and some in the Museum at Versailles, such as the "Battle of Rivoli" (1844); "Bayard on the Bridge of Tarigliano" (1503); "Battle on the Alma" (1875). His "Last Banquet of the Girondists" (1850, Marseilles Museum) is also worthy of notice. He is well known as a painter of panoramas, in which he made great improvements. (See PANORAMA.) He received a medal of the first class in 1840 and the cross of the Legion of Honor in 1846.

PHILIPPSBURG, fil'ips-böörk. A town in the Grand Duchy of Baden, situated near the Rhine, about 17 miles north of Karlsruhe. It was once a noted fortress originally founded by the bishops of Speyer at the beginning of the seventeenth century. It played a conspicuous part in the wars of the seventeenth century, and the fortifications were destroyed in 1800. Population, in 1900, 2546.

PHILIPPSON, fil'ip-zôn, MARTIN (1846-). A German historian, born at Magdeburg. He studied at Bonn and Berlin, became docent at Bonn in 1871, and in 1878 professor in the University of Brussels. From this post he resigned in 1890 after a sharp quarrel with the anti-German student body, and removed to Berlin. Philippson wrote: *Geschichte Heinrichs des Löwen* (1868); *Heinrich IV. und Philipp III.* (1871-76); *Geschichte des preussischen Staatswesens vom Tode Friedrichs des Grossen bis zu den Freiheitskriegen* (1880-82); *Kurfürst Friedrich Wilhelm von Brandenburg* (1879-1901); *Kulturgeschichte Europas seit dem Ausgange des Mittelalters* (1898); and *Das Leben Kaiser Friedrichs III.* (1900).

PHILIPS, AMBROSE (1675?-1749). An English poet, born in Shropshire, probably in 1675.

He graduated from Saint John's College, Cambridge, B.A. in 1696, M.A. in 1700, and was elected fellow of his college, but he resigned his fellowship (1708) and traveled on the Continent. From Copenhagen he addressed (March 9, 1709) an *Epistle to the Earl of Dorset*, which was published in the *Tatler* (No. 12) with warm praise by Steele. The same year appeared his pastorals in Tonson's *Miscellany*, along with Pope's *Pastorals*. Then ensued a controversy as to which poet had better succeeded. Both series are artificial. Philips was angered by a moek commendation of his pastorals which Pope contributed to the *Guardian* (No. 40), and he is said to have hung up a rod at Button's coffee-house for chastising his adversary. No encounter ever took place. Philips was, however, remembered in the *Dunciad*. In ridicule of Philips, Gay wrote the *Shepherd's Week* (1714), descriptive of rustic life with the gilt off. In 1712 Philips was lauded for his adaptation of Racine's *Andromaque*. In 1718-19 he edited an imitation of the *Spectator* called the *Freethinker*. His support of the Government led to his appointment as secretary to Bishop Boulter in Ireland (1724). He also represented Armagh in the Irish Parliament; was made secretary to the Lord Chancellor (1726), and judge of the Prerogative Court (1733). He died in London, June 18, 1749. Philips also translated the odes of Sappho (1713), once thought to be a brilliant achievement. Perhaps his best work is represented by his odes to children (1725-26). Consult: Pope's *Works*, ed. by Elwin and Courthope (10 vols., London, 1871-89); and Johnson's *Lives of the Poets*, ed. by Henley (London, 1896).

PHILIPS, EDWARD (1630-c.1696). An English compiler, the biographer of his uncle, John Milton. The poet's elder and only sister, Ann, on her second marriage left her two sons by her first to the care of her brother, who took them into his own house in Aldersgate. Edward was at that time ten years old, John a year younger, and besides his nephews, Milton took in other pupils. Edward ceased studying with him in 1646, and two years afterwards went to Oxford, where he departed from his Puritan training and joined himself to the Cavalier Party. Edward voiced his royalist sentiments in *The Mysteries of Love and Eloquence*, etc. (1658), containing verses some of which are not original, and to record the Restoration he wrote a *Continuation* (1665) to Barker's *Chronicle of the Kings of England*, which had stopped at 1641. He edited the poems of Drummond of Hawthornden (1656), compiled a dictionary (1658), and was tutor in more than one noble household, but was often obliged to support himself and his family by compilations and translations. John Philips never became reconciled to his uncle, but Edward did. He was the first to praise *Paradise Lost* in the press, spoke in the highest terms of its author in his *Theatrum Poetarum* (1675), and wrote the scant but appreciative *Life of Milton* prefixed to the *Letters of State* (1694).

PHILIPS, FRANCIS CHARLES (1849-). An English novelist and playwright. He was born at Brighton and educated for the army, but he left army life and in 1884 became a barrister. At that time he began, without ceasing to be a barrister, to write both plays and novels. Of the latter the most noted is *As In a Looking Glass* (1885), which was dramatized and played both

by Mrs. Bernard Beere and by Sarah Bernhardt. Among his other books are: *A Lucky Young Woman* (1886); *The Dean and His Daughter* (1887), on which was founded the play of *The Dean's Daughter*, by himself and Sydney Grundy; *Young Mrs. Annesley's Courtship* (1890); *Mrs. Bourverie* (1894); *The Luckiest of Three* (1896); *Men, Women, and Things* (1898), etc. With various collaborators, he is the joint author of the plays *Husband and Wife*, *A Woman's Reason*, *Papa's Wife*, and others.

PHILIPS, or PHILLIPS, JOHN (1676-1709). An English poet, born at Bampton, Oxfordshire, December 30, 1676, and educated at Winchester School and at Christ Church, Oxford. He died at Hereford, February 15, 1709. Philips is still known for two poems: the *Splendid Shilling*, a burlesque (1701), and *Cyder* (1708), on the plan of Vergil's *Georgics*. The first was translated into Latin, and the second into Italian. As a Tory reply to Addison's *Campaign*, Philips wrote *Blenheim* (1705). Philips was among the few poets between Milton and Thomson to cultivate blank verse. Consult Johnson's *Poets*, ed. by Henley (London, 1896).

PHILIPS, KATHERINE (1631-64). An English poet, better known by her literary nickname, 'the Matchless Orinda.' She was born in London, the daughter of John Fowler, a well-to-do merchant. In 1647 she married a Welshman, Hector Philips, son of her mother's second husband; four years afterwards she addressed Henry Vaughan in what seems her first poem; and she soon formed that literary and friendly circle which included Jeremy Taylor and Sir Charles Cotterel, and in which she took the name Orinda. She spent the year 1662 in Dublin and there made many friends among the Royalist Party, with which she had sentimentally allied herself, and translated Corneille's *Pompeé* with great success. *Horace* she did not live to complete, for she died of smallpox in her thirty-third year. Her poems, printed without authorization in 1663, were highly praised by her contemporaries. Her *Letters to Poliarchus* (Sir Charles Cotterel) were published in 1705. Consult Gosse, *Seventeenth Century Studies* (London, 1883).

PHILISTINES (Lat. *Philistini*, from Heb. *P̄lišti*, Philistine). The designation in the Bible of a people who lived on the coast of the Mediterranean, to the southwest of Judea, from Ekron toward the Egyptian frontier, with their eastern limit at Beth-Shemesh. Aside from a few notices in Assyrian and Egyptian inscriptions, we have no knowledge of the early history of the Philistines, except what may be gathered from the Old Testament, in which their relations to the Hebrews are set forth in the course of the historical narratives. The people called Philistines were immigrants who came into Canaan from Caphtor (probably Crete). They are probably identical with the *Plst* of the Egyptian inscriptions, who invaded Egypt from the north in the time of Rameses III. and, being repelled, settled on the Syrian coast. Their settlement in Western Palestine presents, therefore, a parallel to the Hebrew conquest of Canaan. In both cases the new comers dispossessed an older population, and adopted the language and to a large extent the customs of the conquered race. But, while the Hebrews and Canaanites belonged to the same Semitic stock, the

Philistines are aliens in a racial sense. At the time of the Hebrew conquests, they were already in Palestine, and their five central cities, Ashdod, Gaza, Ashkelon, Gath, and Ekron, around which their history, as far as we know it, centres, were presumably already in existence. Hebrew tradition contains a reminiscence of an unsuccessful attempt to drive the Philistines out of their settlements (Jud. i. 18-19).

We reach more certain historical ground in the account of Shamgar's stand against the Philistines (Jud. iii. 31), but evidently the latter retained the supremacy, for we find them subsequently in possession of a sacred palladium of the Hebrews—the chest which was the symbol of Yahweh (I. Sam. iii. 10 sqq.). The story of Samson is of value as showing what were the relations between the Hebrews and Philistines. A victory is signalized for the Hebrews at Mizpah (I. Sam. vii. 10), but if the account is historical, the result was not decisive, for we find that Saul was constantly engaged in warding off their new encroachments, and at Gilboa he and his sons fell in a disastrous battle against them. David, however, though in the early part of his reign obliged to pay tribute to the Philistines, succeeded in routing them in several expeditions. Under Solomon they gave no further trouble, though it is doubtful whether they were ever actually tributary to the Hebrew kingdom. The internal troubles of Judea emboldened the Philistines once more to open resistance. Under Joram they invaded Judea and did considerable damage. Uzziah, however, recovered the lost ground; he overthrew them and dismantled some of their most powerful fortresses—Gath, Jabne, and Ashdod—and erected forts in different parts of their country. Under Ahaz, they rose again, and attacked the border cities of the 'plain' on the south of Judah; and a few years later renewed their attacks, in league with the Syrians and the Assyrians. Hezekiah, in the first years of his reign, subjugated their whole country again, by the aid of the Egyptians, whom we find in possession of five cities. The Assyrians were frequently engaged in conflicts with the Philistines, who at times joined the other Palestinian principalities in opposing the advance of Assyrian arms. In the struggles for supremacy which raged between the Neo-Babylonian monarchy and the Egyptians, Philistia was the constant battleground of both—her fortresses being taken and retaken by each of them in turn; so that the country soon sank into ruin and insignificance. In the time of the Maccabees the Philistines were subjects of the Seleucid rulers and had to suffer occasionally from the Jews, although intermarriages between the two nations were of no rare occurrence. Alexander Balas transferred part of the country to Judea; another part was taken by Alexander Jannæus; Pompey incorporated some of the cities with Roman Syria; Augustus transferred another portion to Herod; and, finally, Salome received a small fragment of it as a principality, consisting of Jamnia, Ashdod, and Ashkelon. But by this time the name of the country had long been lost in that of Palestine, which designated all the territory between Lebanon and Egypt.

Of the state of culture, institutions, etc., of the Philistines we know very little. They appear as a civilized, agricultural, commercial, and warlike nation. They traded largely, and their wares

seem to have been much sought after. Their worship was much akin to that of the Phœnicians and Canaanites. Dagon, Ashtaroth, Beelzebub, and Derceto were the chief deities.

Müller, *Asien und Europa* (Leipzig, 1893); id., *Die Philister* (Berlin, 1899); G. A. Smith, *Historical Geography of the Holy Land* (London, 1897); McCurdy, *History, Prophecy, and the Monuments*, vol. i. (New York, 1894).

PHILISTINISM. A term made popular in England and America by Matthew Arnold. The allusion is to the ancient Philistines, the enemies of the children of light; hence Philistinism, in its modern application, means stolid opposition to the higher intelligence of the age, inaccessibility to ideas; plain, humdrum, respectable conventionalism. The German students first applied the term *Philister* to a townsman or to one who had not been trained in a university; it soon found a foothold in German literature, and reached England through Carlyle. The term has now grown hackneyed and its indiscriminate use has almost emptied it of meaning. Perhaps Leslie Stephen's definition of Philistinism, as "a term of contempt applied by prig to the rest of their species," is the only one that is sufficiently comprehensive. Consult Arnold, "Heine," in *Essays in Criticism*, first series (Oxford, 1865).

PHILISTUS (Lat., from Gk. Φίλιστος, (c.435-356 B.C.). A Greek historian of Syracuse. He assisted the elder Dionysius in securing and maintaining supreme power in Syracuse (c.405 B.C.), but in 386 was banished for marrying a niece of the tyrant without the latter's consent. Recalled soon after the accession of Dionysius the younger, he brought about the banishment of Dion and Plato, and according to the latter, employed his talents in defense of the despotic policy of Dionysius. In B.C. 356, however, he was defeated in a naval battle by Dion and the revolted Syracusans, and either committed suicide or was killed by the populace. He left *Sicelica* (Σικελικά), a history of Sicily from the earliest times to B.C. 362, in thirteen books, begun in exile. According to the testimony of the ancients, by whom he is frequently mentioned, he sought in this work to palliate the despotic deeds of Dionysius, in order to secure his own return from exile. In style he was a close, though unsuccessful, imitator of Thucydides. The few extant fragments of Philistus are edited in C. Muller's *Fragmenta Historicorum Græcorum* (Paris, 1841).

PHILLEO, PRUDENCE (CRANDALL). See CRANDALL (PHILLEO), PRUDENCE.

PHILLIMORE, SIR ROBERT JOSEPH (1810-85). A distinguished English jurist, born in London. He was educated at Westminster and Christ Church, Oxford, where he graduated in 1831, and then became a clerk of the Board of Control. Soon afterwards he was called to the bar, where he acquired a large practice, and was made a Queen's counsel. In 1844 he was made Chancellor of the Duchy of Chichester, and later was a member of Parliament. He was made judge of the Cinque Ports in 1855, advocate-general in admiralty, 1862, when he was knighted, and in 1867 judge of the High Court of Admiralty and of the Arches Court of Canterbury. He was

Judge Advocate-General, 1871-73, and made Master of the Faculties in the latter year. In 1875 he resigned his other offices, and was appointed judge of the Admiralty and Probate Division of the High Court of Justice, retiring in 1880. The most valuable of his numerous legal works is his *Commentaries upon International Law*, 4 vols. (3d ed., London, 1879-89). Among his other writings are *Memoirs and Correspondence of George, Lord Lyttleton, 1731-73* (ib., 1845); *The Ecclesiastical Law of the Church of England*, largely taken from the work of Burns upon that subject (2d ed., ib., 1895).

PHILLIMORE, SIR WALTER GEORGE FRANK (1845-). An English jurist, born in London. He was educated at Oxford, where he had a particularly distinguished career, became a barrister of the Middle Temple in 1868, and received the Patent of Precedence there in 1883. He stood high in the Admiralty Court, and in ecclesiastical circles as vice-president of the English Church Union, and chancellor of the Diocese of Lincoln. He wrote a *Book of Church Law*, and edited Robert Phillimore's *Ecclesiastical Law of the Church of England*, and a third edition of vol. iv. of that author's *International Law*.

PHILLIP, JOHN (1817-67). A Scotch genre and portrait painter. He was born at Aberdeen, April 19, 1817. His boyhood was spent in poverty, but his remarkable talent attracted the attention of Lord Panmure, who enabled him to study at the Royal Academy. He at first painted Scotch genre subjects in the manner of David Wilkie, but a voyage to Spain in the summer of 1851-52, made for the benefit of his delicate health, completely changed his style. Influenced by Valazquez and by the bright colors of nature about him, he adopted the rich coloring by which his best works are distinguished. His work having attracted the attention of Sir Edmund Landseer, who introduced him to the Queen, he received a number of royal commissions, among which was a large ceremonial picture, "The Marriage of the Princess Royal with the Crown Prince of Germany" (1860). He visited Spain in 1856-57 and again in 1860, his last visit being a time of great artistic activity. After a journey to Rome and Florence in 1866, for the purpose of studying Titian, he was stricken with paralysis and died at Kensington (London), February 27, 1867.

Among the best paintings of his early period are: "Wallace and His Schoolfellows at Dundee" (1846); "Presbyterian Catechising" (1847); "Baptism in Scotland" (1850); "Scotch Washing" (1851). After his visit to Spain he executed "The Spanish Gypsy Mother" (1853), the "Letter-Writer of Seville," and the "Dying Contrabandista" (1858), all in the Royal Collection. Other important works are: "A Huff" (1859); the "Prison Window" (1857); "La Bomba" (1862-63); and his masterpiece, "La Gloria" (1864), in the National Gallery of Scotland. In the Metropolitan Museum, New York, is his "Gossips at the Well." He also produced a number of forcible portraits, including those of Sir J. E. Millais (1843), the Prince Consort (1858), and the Princess Beatrice (1860).

PHILLIPS. The name of a family identified with the founding of Phillips Academy (q.v.). SAMUEL, JR. (1751-1802), politician and philanthropist, was born at Andover, Mass. He grad-

nated at Harvard in 1771 and was elected in 1775 to the Provincial Congress, of which he continued to be a member until 1780, when he was elected a member of the Massachusetts State Senate, of which for seventeen years (1785-1802) he was presiding officer. From 1781 until 1798 he was also judge of the Court of Common Pleas for Essex County, and in 1891 he was elected Lieutenant-Governor by the Federalists. He is best known, however, as the founder of Phillips Academy at Andover in 1778. In this project he interested his father, SAMUEL (1715-90), who graduated at Harvard in 1734, and afterwards represented Andover in the General Court; his uncles, JOHN (1719-95), who graduated at Harvard in 1735, settled at Exeter and was for many years a member of the Council of New Hampshire, and WILLIAM (1722-1804), who held important political offices in Massachusetts; and the latter's son, WILLIAM, JR. (1750-1827), who was in twelve successive elections chosen Lieutenant-Governor of Massachusetts. Their liberality enabled the academy to take a high position from the day of its opening. A few years later John Phillips, who was childless, founded at Exeter a similar academy, to which at his death he bequeathed two-thirds of his estate, the remaining third going to Phillips Andover. During his lifetime he also endowed a professorship at Dartmouth College, and made liberal gifts to Princeton.

PHILLIPS, ADELAIDE (1833-82). An American opera singer. She was born at Stratford-on-Avon, England, but when she was seven years old her family emigrated to America and settled in Boston. She first appeared at the Boston Museum, in 1843, as "Little Pickle," and played *soubrette* parts in that theatre and at the Walnut Street Theatre, in Philadelphia, until 1852, when, having revealed the possession of a contralto voice of remarkable sweetness and compass, she was sent to Italy for study, an advantage obtained largely through the efforts of Jenny Lind, who organized a subscription for the purpose. She remained abroad two years, and made a successful *début* in Breseia, in 1853, in *Semiramide*. The following year she returned to the United States, and appeared in concert in the Music Hall, Boston, making her American *début* in opera at the Academy of Music, New York, March 17, 1856, in the part of "Azucena" in Verdi's *Il Trovatore*. In 1861 she sang in the Italian Opera House in Paris. She was the leading contralto singer of America for many years. She died at Karlsbad.

PHILLIPS, HENRY (1838-95). An American archaeologist, born in Philadelphia. He was admitted to the bar in that city in 1859, but, because of ill health, devoted himself to the study of numismatics, philology, and archaeology. His publications include *History of American Colonial Paper Currency* (1865); *History of American Continental Paper Money* (1866); *Pleasures of Numismatic Science* (1867); a volume of Spanish and German poetry (1878); Chamisso's *Faust* (1881); and four volumes from the Hungarian, German, and Spanish (1884-87).

PHILLIPS, JOHN (1800-74). An English geologist, born in Wiltshire. After receiving an elementary education he joined his uncle, William Smith, in geological investigations in various parts of England. In 1825 he was made curator of the Yorkshire Philosophical Society, and in 1834 was appointed professor of geology at King's

College, London. Resigning this office in 1840, he served successively as geologist on the survey of Great Britain, professor of geology at Trinity College, Dublin, and at Oxford, and Keeper of the Ashmolean Museum. He was president of the Geological Society in 1859-60. He contributed numerous papers to scientific journals, and also wrote the following separate works: *Illustrative of the Geology of Yorkshire* (1822-36); *Guide to Geology* (1834); *Treatise on Geology* (1837); *Geological Map of the British Isles* (1842); *Memoirs of William Smith* (1844); *Vesuvius* (1869); and *The Geology of Oxford and the Valley of the Thames* (1871).

PHILLIPS, JOHN ARTHUR (1822-87). An English geologist, born at Polgooth, near St. Austell, Cornwall, and educated at the Paris School of Mines. He was appointed chemist to the Admiralty commission engaged in finding the most suitable coal for burning at sea, and afterwards made valuable researches in mineralogy. He inspected gold mines in California and elsewhere, and between 1875 and 1878 he wrote a series of important monographs on the rocks of his native country. He published *The Mining and Metallurgy of Gold and Silver* (1867), and *The Elements of Metallurgy* (1874), but his chief work was *A Treatise on Ore Deposits* (1884).

PHILLIPS, PHILIP (1834-95). A Methodist evangelist and singer. He was born in Chautauqua County, N. Y. After the age of nineteen he devoted all his time to the study and use of music. During the Civil War he sang much for the benefit of the Christian Commission; he became musical editor for the Methodist Book Concern in 1866; and made a musical tour around the world in 1872, holding evenings of song in all lands. On his return he gave 200 nights for the Sunday School Union in England; subsequently he traveled with D. L. Moody. He produced a number of hymn books, such as *Early Blossoms* (1860); *The Singing Pilgrim* (1866); *American Sacred Songster*, prepared for the British Sunday School Union (1868); *Hallowed Songs* (1871); *Our New Hymnal* (1894); and, with his son, *Bright Gems* (1895). Several of these had a very large sale.

PHILLIPS, STEPHEN (1868—). An English poet, born at Summertown, near Oxford, July 28, 1868, son of the Rev. Stephen Phillips, afterwards precentor of Peterborough Cathedral. Having attended the grammar school at Stratford-on-Avon and at Peterborough, he studied for the civil service and entered Queen's College, Cambridge, in 1886, but at the end of the first term he joined F. R. Benson's company of Shakespearean players, with whom he stayed six years. He traveled through the country and played at the Globe Theatre in London. Among his parts were Iago, the ghost in *Hamlet*, Prospero, Brutus, and Sir Andrew Aguecheek. Leaving the stage, he became a lecturer on English history in Wolfram and Needham's classes for army candidates, but soon he adopted literature as a profession. In June, 1890, with three other authors he published in London a booklet of verse entitled *Primavera*. In 1894 followed *Eremus*, which won the praise of Symonds, Jowett, and Stopford Brooke. *Christ in Hades and Other Poems* (1896; fourth edition with additions, 1897), and *Poems* (1897), containing "Marpessa," secured for the author a high rank among

recent poets. The *Poems* won from the London Academy the award of one hundred guineas for the best verse of the year. Commissioned by George Alexander to write a verse tragedy for Saint James's Theatre, Phillips composed *Paolo and Francesca* (1899), a poetic tragedy in four acts. The blank verse of this lyric tragedy recalls the Elizabethans, but its simple structure is more nearly akin to the French classic drama. For Beerbohm Tree Phillips wrote his second play, *Herod* (1900), a tragedy in three acts on an Elizabethan theme. *Ulysses*, a dramatic poem, appeared in 1902, and in the same year a play called *David and Bathsheba*.

PHILLIPS, THOMAS (1770-1845). An English portrait painter, born in Dudley, Warwickshire. He was a pupil of Francis Eginton, a glass painter of Birmingham, and afterwards worked under Benjamin West on the windows of Saint George's Chapel, Windsor. He began to exhibit at the Royal Academy in 1791 and was elected to that institution in 1808. There he succeeded Fuseli as professor of painting and his *Lectures on the History and Principles of Painting* were published in 1833. His portraits include those of the Prince of Wales, William Blake (in the National Portrait Gallery), Napoleon (at Petworth), Lord Byron (two pictures), Crabbe, Lord Brougham, David Wilkie (in the National Gallery), Walter Scott, Hallam, Faraday, and Davy.

PHILLIPS, WENDELL (1811-84). An eminent American orator and reformer, born in Boston. He was educated at Harvard, graduating in 1831—the year of the first appearance of the *Liberator*. After a three-years' course at the Cambridge Law School, he was admitted to the Suffolk County bar; but he was little interested in professional eminence. On October 21, 1835, from his office window he indignantly saw Garrison dragged at a rope's end by a respectable mob; in 1836 he joined the Abolitionists, and thereafter was occasionally heard at meetings of the American Anti-Slavery Society. He came at once into prominence by his Faneuil Hall speech of December 8, 1837. At the instance of Dr. W. E. Channing, a public assembly had convened to protest in a suitable manner against the murder of the Rev. E. P. Lovejoy (q.v.) at Alton, Ill. This purpose seemed likely to be defeated by J. T. Austin, Attorney-General of Massachusetts, who commended the Alton rioters, and affirmed that Lovejoy "died as the fool dieth." To this Phillips made a brilliant and crushing reply, whose eloquence he never surpassed, and which has been ranked by Curtis with Henry's oration at Williamsburg, and Lincoln's Gettysburg address. From that time he was an Anti-Slavery leader, preëminently the orator of the movement. In 1839 he withdrew from the practice of law through scruples against compliance with the attorney's oath to the Constitution, and later he refused to stand for a Congress which he could not enter without swearing allegiance to that same Constitution. He called for the immediate and complete abolition of slavery, declared the Church *particeps criminis* for its attempt to justify slavery by the Scriptures, opposed colonization for the negro, discontinued voting, and regarded disunion as the best means for accomplishing emancipation. He was not, however, like Garrison, a non-resistant. In the Abolitionist

divisions of 1839-40, he with Garrison opposed the organization of the Abolitionists in a political party, and the attempt to bar any from the anti-slavery platform on the ground of religious beliefs. In 1840 he was the representative of the Massachusetts Abolitionists at the London World's Anti-Slavery Convention. Differences arose between himself and Garrison in 1864, in regard to Lincoln's reelection, which he did not favor; and in 1865 these differences were renewed when he advocated and Garrison opposed the continuance of the Anti-Slavery Society. His contention was that the work of the society was not finished until the negro obtained the suffrage. As a result he was elected in Garrison's stead (1865) to the presidency of the society, which was dissolved in April, 1870, upon the passing of the Fifteenth Amendment. Phillips was prominently active in the various controversies of the Reconstruction. Yet his task did not end there. "Let it not be said," he once wrote, "that the old Abolitionist stopped with the negro, and was never able to see that the same principles claimed his utmost effort to protect all labor, white and black, and to further the discussion of every claim of humanity." Accordingly, he spoke in behalf of Ireland, Crete, the Indian, prison reform, the abolition of capital punishment, prohibitory legislation regulating the sale of liquor, the 'greenback theory,' and in connection with the labor question urged that vast combinations of capital with unlimited monopolies and powers tend to make the rich richer and the poor poorer. In 1870 he received about 20,000 ballots as labor reform and temperance candidate for the Governorship of Massachusetts.

Phillips must be compared among American orators to Everett, Clay, and Webster; and his achievement is, perhaps, to be reckoned greater than that of any of these, when it is considered that whereas they represented a strong political organization or powerful conservative opinion, he attacked existing prejudices and institutions, for years spoke to hostile audiences, was denounced by the two great parties, and belonged to none. His manner was that of "simple colloquy," so that Greeley said Phillips made one think it easy to be an orator. His voice was in the baritone register, used largely in what elocutionists call the upper chest notes, and remarkable not so much for its compass, volume, or intensity as for its *timbre*. In gesture or general action he was sparing. He seldom employed the dramatic mode of expression. But in invective or epigram he was unsurpassed, he possessed wit, which most other notable American orators have lacked, and he told an anecdote with much skill. Phillips was not a scholar in the restricted sense, for this the demands made upon his time as a public speaker did not permit. But his reading was considerable, and he could always find illustrative material in the one subject he was accustomed to say he knew thoroughly—the great English Revolution. In addition to his anti-slavery and other reform speeches, he appeared in various lyceum addresses, the most noteworthy of which are *The Lost Arts*, *Toussaint l'Ouverture*, and *Daniel O'Connell*, and in 1881 he made a distinguished oration on *The Scholar in a Republic* at the centennial anniversary of the Phi Beta Kappa of Harvard. During anti-slavery days he always offered to speak without remuneration and pay

his expenses if he might substitute an anti-slavery for a literary subject. He wrote for the *Liberator* and the *Anti-Slavery Standard*, and published a number of pamphlets, including *The Constitution a Proslavery Compact* (1844); *Can Abolitionists Vote or Take Office Under the United States Constitution?* (1845); *Review of Spooner's Unconstitutionality of Slavery* (1847); *Review of Webster's Seventh-of-March Speech* (1850); *Review of Kossuth's Course* (1851); *Defense of the Anti-Slavery Movement* (1853). Collections of *Speeches, Lectures and Letters* have appeared at Boston, the first series, edited by James Redpath, in 1864, the second by T. C. Pease in 1892. These are edited from the best stenographic reports. There are two inadequate biographies, one by Austin (Boston, 1888), the other by Martyn (New York, 1890; American Reformers Series). Consult also works dealing with the anti-slavery struggle.

PHILLIPS ACADEMY. An important boys' school at Andover, Mass., commonly known as Phillips Andover. It was founded and opened in 1778 through the gifts of members of the Phillips family. The school was incorporated in 1780, and in 1807 the trustees were empowered to receive and hold funds for a separate theological institution, and the Andover Theological Seminary was accordingly established in the following year. In 1830 the Teachers' Seminary was established in anticipation of the normal schools, but in 1842 was merged in the parent academy, and is its present scientific department. In 1901 an archaeological department, with valuable collections and an endowment for instruction, research, and publication, was established by two anonymous donors. The Academy, with its sister institution at Exeter, has always been regarded as a typically democratic American school. During the early years of its history it had as students many of the famous men of the country. The equipment has in recent years been largely increased by new buildings, among them several dormitories and a gymnasium. The standards of Yale and Harvard, to which most of the graduates go, form the basis on which the work of the school is arranged. The academy had in 1902 an attendance of 400 and 24 instructors. The endowment was \$400,000, the gross income \$70,000, and the college property was estimated at \$500,000, exclusive of invested funds. The library contained 60,000 volumes.

PHILLIPS ACADEMY. One of the oldest and most renowned of American schools, at Exeter, New Hampshire, commonly known as Phillips Exeter. It was founded in 1781 and opened in 1783. The school was the first educational institution incorporated by the Legislature of New Hampshire, and has its name from John Phillips, its founder, who was a generous benefactor of Dartmouth College and of Phillips Academy, Andover, Mass. It early gained a national reputation, and drew students from all sections of the country. The alumni in 1903 numbered about 7000, among its earlier students being Daniel Webster, George Bancroft, Edward Everett, John A. Dix, and Jared Sparks. In 1902-03 over 300 students were enrolled and the faculty numbered 16. The school buildings, many of which have been built since 1886, include well-equipped laboratories, fine dormitories, an administration building, gymnasium, and a

building designed as a common dining-room and for the entertainment of visiting alumni. The buildings with their equipment are valued at about \$300,000. The endowment in 1902 was about \$400,000, and the annual income \$100,000. Characteristic of the school have been its democratic spirit and its successful application of a system of self-government.

PHILLIPSBURG. A town in Warren County, N. J., on the Delaware River, opposite Easton, Pa., and on the Pennsylvania, the Lehigh Valley, the Lackawanna, and the Central of New Jersey railroads (Map: New Jersey, B 2). It possesses valuable advantages for an industrial centre, the river affording good water-power and the railroads making accessible a supply of coal and iron ore. Its manufacturing interests are extensive, and include shops of three of the railroads that enter the town, also iron furnaces, sheet iron mills, foundries and machine shops, stove works, boiler works, horseshoe mills, drill works, and large silk mills. Settled in 1749, Phillipsburg was incorporated in 1861. It is governed under a revised charter of 1875, by a mayor, annually elected, and a council which controls appointments of most of the subordinate officers. Population, in 1890, 8644; in 1900, 10,052.

PHILLPOTTS, EDEN (1862—). An English novelist, son of Captain Henry Phillpotts. He was born at Mount Aboo, in India, November 4, 1862, and was reared at Plymouth, England. At the age of eighteen he became clerk in the Sun fire insurance office—a position which he held for ten years. A number of earlier novels were followed by two great successes, *Lying Prophets* (1897) and *Children of the Mist* (1898). In these novels Phillpotts depicted Devonshire life with remarkable power and beauty. In their coloring they recall Blackmore, and in their tragedy they are akin to Hardy. There have since followed *Loup Garou* (1899); *The Human Boy* (1899), which is a volume of stories illustrating schoolboy humor; *Sons of the Morning* (1900); *The Striking Hours* (1901), a collection of short Devonshire stories; *The Good Red Earth* (1901); and *The River* (1902).

PHILOBIBLON. A prose treatise by Richard Aungerville, known as Richard de Bury, Bishop of Durham (1345). The author, an enthusiastic collector of books, and founder of a library at Oxford in connection with Durham College, writes in praise of learning, of the value and proper care of books, with advice to students. It was printed first at Cologne in 1473, at Paris in 1500, and at Oxford in 1599. The latest English translation is that of E. C. Thomas (London, 1885).

PHILO BYBLOS. See SANCHONIATHON.

PHILOCORUS (Lat., from Gk. Φιλόχορος). A Greek historian who is said to have lived at Athens between B.C. 306 and 260. According to Suidas, he was one of the bitterest opponents of Demetrius Poliorcetes and of his son, Antigonos Gonatas, and was put to death by the latter after the conquest of Athens (about B.C. 260). He is known chiefly by his *Atthis*, a history of Athens from the earliest times to B.C. 262, in seventeen books. By later writers it is frequently referred to as one of the most thorough and reliable of the special histories of Attica. Important fragments are preserved in Müller's *Fragmenta*

Historicorum Græcorum (Paris, 1841). Consult: Streuge, *Quæstiones Philochoræ* (Göttingen, 1868), and Siebelis's edition (Leipzig, 1811).

PHILOCTETES (Lat., from Gk. Φιλοκτήτης, *Philoktētēs*). A Greek chieftain who inherited the bow and arrows of Heracles. He started with seven ships for the Trojan War, but was bitten on the way by a serpent at Lemnos. On account of the stench of the wound, the other Greeks left him behind and went on to Troy. As an oracle, however, declared that Troy could only be taken by the arrows of Heracles, Odysseus and Diomedes went to Lemnos to fetch Philoctetes. He accompanied them to Troy, slew Paris, and returned safely home. The drama *Philoctetes* by Sophocles is still extant, the legend having been also dramatized by Æschylus and Euripides.

PHILODEMUS (Lat., from Gk. Φιλόδημος). An Epicurean philosopher of the first century B.C. He was born at Gadara in Syria, and studied under Zeno. Besides thirty-four epigrams, mostly erotic, in the Greek anthology, Philodemus wrote works on philosophy, of which copies much mutilated were discovered at Herculaneum. They are: *De Rhetorica*, edited by Gros (1840) and by Sudhaus (1892-95); *De Musica*, edited by Kempke (1884); *De Vitis*, by Götting (1830) and Ussing (1868); *De Ira* and *De Pietate*, by Gomperz (1864-66); and *De Morte*, by Mekler (1886). Martha makes him the editor of Lucretius and many attempts have been made to prove that Cicero got his knowledge of Epicureanism from Philodemus and so from Zeno.

PHILO JUDÆUS (Lat., from Gk. Φίλων Ἰουδαῖος, *Philōn Ioudaios*, Philo the Jew). A Jewish-Hellenistic philosopher, born at Alexandria about B.C. 25. He belonged to one of the most wealthy and aristocratic families—his brother Alexander was the Alabarch or president of the Jewish colony at Alexandria—and he received the most careful Jewish education, consisting largely of a study of the Old Testament in the Septuagint version. He also became acquainted with the writings of the Greek philosophers. He went to Rome, A.D. 39 or 40, as the advocate of his Alexandrian brethren, who had refused to worship Caligula in obedience to the Imperial edict. He has left an account of this embassy, the result of which was not satisfactory. Of his life we know little except what is recorded above.

While strict in all that pertained to ceremonial and ritual, in doctrinal matters Philo was a bold allegorizer. A literal interpretation of the Scriptures he regarded as superstitious and mean. Especially did he explain away all theophanies recorded in the Old Testament, as told in accommodation to the sensuous character of human minds, which needed anthropomorphic representations of supersensible truth.

His writings develop his ideas and his system in the two directions indicated. In that division of his writings principally which treats of the creation (*Kosmopoia*), he allows allegory to take the reins out of his hands; in that on the laws (*Nomoi*), on the other hand, he remains remarkably sober and clear, extolling the Mosaic legislation throughout, at the expense of every other known to him. In a very few instances only he is induced to find fault, or to alter

slightly, by way of allegory, the existing ordinances.

His idea of God is a preëminently theosophic not a philosophic one. God alone is the real good, the perfect, only to be imagined as the primeval light, which cannot be seen by itself, but may be known from its rays, that fill the whole world. He has no attributes, and therefore no name, and reveals himself only in designations expressive of this 'inexpressibility.' He is better than virtue and knowledge, better than the beautiful and the good (*Kalokagathia*), simpler than the one, more blissful than bliss. He is the existing unity or existence itself, self-sufficient, free from pain and fear and participation in evils, and full of happiness. Dynamically God is omnipresent, but not really. Indeed, so far is God really from filling the world with his presence that the world, on the contrary, finds its place in God. And yet the God who comprehends within himself the material universe is so exalted above the world and so remote from it that a point of contact cannot be found between them; hence the need of an intermediate class of beings to stand between them. These were found in the spiritual world of ideas, which are not only 'ideals,' or types, in the Platonic sense, but real, active powers, surrounding God like a number of attendant beings. They are his messengers, who work his will, and by the Greeks are called good demons; by Moses, angels. There are very many different degrees of perfection among them. Some are immediate 'serving angels;' others are the souls of the pious, of the prophets, and the people of Israel, who rise higher up to the deity; others again are the heads and chief representatives of the different nations, such as Israel does not need. The *Logos* comprises all these intermediate spiritual powers in his own essence. (See article *LOGOS* for Philo's views on this part of his system.) Man is a microcosm, a little world in himself, a creation of the *Logos*, through whom he participates in the deity. The ethical principles of Stoicism Philo identified with the Mosaic ethics, in which the ideal is most exalted moral perfectibility or sanctity, and man's duties consist in veneration of God, and love and righteousness toward fellow-men. Philo holds firmly the belief in immortality. Man is immortal by his heavenly nature; but as there are degrees in his divine nature, so there are degrees in his immortality, which only then deserves this name when it has been acquired by an eminence of virtue. There is a vast difference between the mere living after death, which is common to all mankind, and the future existence of the perfect ones. Virtue and sin both have all their rewards within themselves; but the soul, which is 'pre-existing,' having finished its course in the sublunary world, carries this consciousness with it in a more intense and exalted manner. Paradise is oneness with God; there is no hell with bodily punishments for souls without a body, and no devil in the Philonic system. (For the relation between Philo, as the representative of the Judeo-Alexandrian philosophy, and other contemporary philosophic tendencies, see *NEO-PYTHAGOREANISM*). Of the many works left under his name, several have been declared spurious, but in some cases without much show of reason. His writings have been published by Richter (Leipzig, 1828-30) and by Tauchnitz

(ib., 1851-54). See Gfrörer, *Philon und die alexandrinische Theosophie* (Stuttgart, 1831); Dähne, *Geschichtliche Darstellung der jüdisch-alexandrinischen Religionsphilosophie* (Halle, 1834); Wolff, *Die philonische Philosophie* (Leipzig, 1849); Delaunay, *Philo d'Alexandrie* (Paris, 1867); Drummond, *Principles of the Jewish-Alexandrian Philosophy* (London, 1877); id., *Philo Judæus* (ib., 1888); Freudenthal, *Die Erkenntnislehre Philos von Alexandria* (Berlin, 1892).

PHILOLA'US (Lat., from Gk. Φιλόλαος) (c.450 B.C.). A Pythagorean philosopher, born at Tarentum or Croton. Little is known of his life. Some fragmentary writings are attributed to him, in which he sets forth the teachings of Pythagoras. The authenticity of these writings has been the subject of serious study and of dispute among critics. To him is ascribed a knowledge of harmonic ratio, and of the fact that the number of vertices of a cube is an harmonic mean between the number of faces and the number of edges. He seems also to have known with reasonable exactness the periods of revolution of the planets. Consult: Boeckh, *Philolaus des Pythagoräers Lehren, nebst Bruchstücken seines Werkes* (Berlin, 1819); Schaarschmidt, *Die angebliche Schriftstellerei des Philolaus* (Bonn, 1864).

PHILOLOGICAL ASSOCIATION, AMERICAN. A learned society, organized at Poughkeepsie, N. Y., in July 1869, from the Classical Section of the Oriental Society (q.v.), with Prof. William D. Whitney, of Yale, as the first president. Its object is the advancement and diffusion of philological knowledge. It has a membership of about 600, and its annual meetings are held in such cities as the society may, from year to year, select. The publications of the association are annual volumes of *Transactions*, in which are printed in full such papers as the executive committee may select, and *Proceedings*, giving an account of the annual meeting and brief abstracts of all papers presented to the society.

PHILOLOGICAL SOCIETY, BRITISH. A learned society founded in London in 1842, to investigate and promote the study and knowledge of the structure, the affinities, and the history of languages. It added to these objects the publication of the 'New English Dictionary,' work upon which was begun in 1857, under the editorial charge of Dr. James A. H. Murray, assisted by many scholars and men of science in Great Britain and the United States. The first part was published in 1884, and the bound volumes issued to 1903 bring the Dictionary down to the letter M, though some parts in O and Q have also been sent out in pamphlet form. The society has its headquarters at University College, London, and holds its annual meeting in May and monthly meetings from November to June, at which papers are read, the more important ones being afterwards published in volumes of *Transactions*, distributed to members without charge, while summaries or synopses of the other papers are printed in the monthly *Abstract*, also published by the society.

PHILOLOGY (Lat. *philologia*, from Gk. φιλολογία, love of literature and learning, love of language and history, from φίλος, *philos*, dear + λόγος, *logos*, word). In modern English usage,

the science of comparative linguistics. As speech may be studied either in its expression or in its origin, philology may occupy itself with linguistic expression, with literature, or with the genesis and laws of language. French and German scholars usually employ the word in the former sense, and many English scholars prefer to understand by philology the study of literary expression, even including all that is revealed through literature. Nevertheless, although this is perhaps the more legitimate use of the word, yet the tendency of the day, even among French scholars, and still more among English-speaking people, is to confine philology to the study of language, and to divide this study into (a) linguistics proper, including phonetics, and (b) comparative philology, the study of language by a comparison of different languages in the same family. Languages may be divided roughly, and merely for convenience without scientific accuracy, into several types. Of these the most important are the isolating or monosyllabic, the agglutinative, with its subdivision the incorporating or synthetic, the inflectional, and the analytic. The isolating group, formerly supposed to be represented by Chinese, is characterized by invariable monosyllabic roots. The opinion which once considered this group to be the most primitive is now rejected by many who hold that the type represents, on the contrary, the culmination of a long linguistic evolution. The agglutinative type, which includes the majority of languages, such as the Dravidian, Malayo-Polynesian, Uro-Altaic, and African, is marked by the addition of prefixes, suffixes, and infixes to the so-called root (q. v.) or base. These additions have, at least at first, distinct meanings of their own, but in course of time the meanings become obscured, the particles themselves become fused in signification with the base, and lose their individuality. The result is the type of language called inflectional. (See INFLECTION.) In the incorporating or polysynthetic languages, represented by the American Indian groups, the verb absorbs the name, pronouns, adjectives, and adverbs, thus marking a higher degree of agglutination than the agglutinative languages themselves. The analytic languages are a development of the inflectional. In time the inflections tend to become weakened in force, and to require the help of pronouns, prepositions, and auxiliary verbs. When the inflections have in the main disappeared, and their places have been taken by individual words, the language is termed analytic. To this group belong such languages as English, French, Italian, Persian, and Hindustani, as distinguished from the inflectional groups represented by the Semitic and Indo-European families, which include Hebrew, Arabic, Sanskrit, Greek, Latin, and German. It is, however, customary to confine comparative philology to the study of the group of Indo-European languages, though there is no reason why the term should not be applied to any other group as well. The different aspects of philology thus outlined are treated under different heads, to which the reader is referred for special discussion. See the articles on LANGUAGE, for the psychology of language; ALBANIAN, ARMENIAN, INDO-IRANIAN, etc., for special branches; and for classical philology, see the articles on GREEK LANGUAGE and ITALIC LANGUAGES.

HISTORY OF COMPARATIVE PHILOLOGY. Until the discovery of Sanskrit no comparative philology was possible. Sir William Jones in 1786 and Schlegel in 1808 connected Sanskrit with Greek and Latin; but Franz Bopp (q.v.) first correlated the facts observed by others and founded the science. Approaching the subject from the philosophical side, Bopp devoted himself to glottogonic problems, his chief aim being to discover phonetic laws and the genesis of forms. He was at first influenced by Friedrich Schlegel, and opposed the doctrine of mechanical affixes (called agglutination), holding rather to an inner inflection as the index of different relations, though he admitted into the root (in the aorist, etc.) the abstract verb *as*, 'be.' But this view (1816) was soon changed, and Bopp in 1819 himself opposed this philosophy of language and taught that verbal endings, *-ti* for example, are really pronominal in origin. In his *Conjugations-system* and *Vergleichende Grammatik* (1833) he went still further, assuming a pronominal origin for case-endings as well as verbal endings (*-s* of the nominative being *sa*, 'he,' etc.). It is unnecessary to give in detail the mixture of fact and fancy which from a later point of view, alternately adorns and disfigures this first exhaustive attempt to create a science of grammar. His monumental work was followed by the equally important *Geschichte der deutschen Sprache* (1848) of Jakob Grimm (q.v.), who with Rask (q.v.) extended the comparison of forms and discovered phonetic laws of change (see below). After Grimm, the *Etymologische Forschungen* (1836) of Pott (q.v.) established a rationalized system of etymology for the whole group of Indo-European languages. Bopp, Grimm, and Pott may justly be called the creators of the comparative study of language. Agglutination, monosyllabic roots, *a*, *i*, *u*, as the three essential vowels, and a mother-language, these characterize the belief of the first period of the study represented by them. This period extends to the appearance of Schleicher's (q.v.) *Compendium* (1862), which systematized the views of his predecessors, while adding to them his own more stringent but false conception of language as a living organism, which in his opinion should be studied by the methods of natural science. An increasing respect for 'phonetic law' (q.v.) marks the close of this period, in which the names of Schleicher and Georg Curtius (q.v.), the latter being one of the first to insist on phonetic regularity, are most prominent. Different languages now began to be studied more carefully, each for itself, and the laws of each more strictly established. New problems arose, such as that of the parent language and primitive vocalism, but Schleicher stood on the platform of his predecessors as regards the old problems. The parent speech Schleicher represented as the root of a tree, with trunk, branches, and twigs representing descendant languages and dialects (the so-called *Stamm-baum-Theorie*). Like Curtius, he held that the simpler vocalism of Sanskrit was more antique than the variation shown in Europe, and believed that Sanskrit *a* was older than Greek *α*, *ε*, *ο*.

Ten years later, in 1872, Johannes Schmidt (q.v.) published his *Verwandtschaftsverhältnisse der indogermanischen Sprachen*, which put the interrelation of the different Indo-European languages in a new light. Instead of a family-tree with its organic growth and dialect-twigs,

Schmidt set forth the *Wellentheorie*, according to which the different languages had rolled away like waves from a common centre. This view replaced Schleicher's and in a somewhat modified form has been adopted by Leskien, Schrader, and other scholars of the present day. According to it, certain words and forms are explained as being common to one section till that splits up and so leaves the contiguous peoples in possession of a common linguistic property, while those dwelling farther apart possess linguistic property which, although originally practically identical, has become so differentiated as frequently to be mutually unintelligible. The obvious objection is that some wave-segments may have lost material formerly possessed and others made for themselves what is also found in other segments. This change of view is paralleled by that in regard to vocalism. Instead of assuming that the primitive language had only *a*, *i*, *u*, and that Sanskrit *a* was an older phase as compared with Greek *α*, *ε*, *ο*, the scholars of the second period, which began about 1862, Brugmann, Osthoff, Collitz, and others, showed that the varied phase was older. During this period, as for a dozen years previously, much of the best effort of philologists was directed toward individual languages, the publication of texts, lexicons and grammars, which gave much new material in many directions, notably in the Indo-Iranian field. Benfey, Roth, Böhtlingk, Westphal, Curtius, and Max Müller thus furthered the cause of general comparative philology. Moreover, new languages were added to the group, such as Albanian, Armenian, and Phrygian. At this time also began to be discussed afresh the problem of new formations. The answer to this was given in Whitney's enunciation of the theory of analogy (q.v.). By imitation of the old, the new is produced. But especially were the scholars now calling themselves young grammarians insistent upon one principle which became a shibboleth. This was the invariability of phonetic law (q.v.). In the seventies and eighties the various philologists of note in Germany were more or less split up into cliques headed by Georg Curtius, Fick, Schmidt, Brugmann, and others, but this was due less to a radical difference than to personal feeling and may be passed over. In America, Whitney centred his attention upon the fundamental question of the origin and growth of language, and in so doing came into conflict with Max Müller. Müller claimed that language gives conceptions which could not exist without speech. Thought and word were, in his view, convertible terms. Whitney held, on the other hand, that words are only signs associated with conceptions, and that every language known to us is a body of conventional signs for ideas. Müller denied that any man can change a language; Whitney maintained that individuals initiate changes subsequently accepted by the community, which makes the changes parts of its language by the simple employment of them. To Müller, language-study was a physical science, even in his final revision of the views first expressed in 1862. In all this, Müller showed that he was of the school of Schleicher, whom, indeed, he cited as his chief authority in teaching that the study of language is a physical science. Language is, however, a human institution, not a physical science, and the failure to recognize this fact undermines the foundation of Müller's

view. Müller further held that no new roots have ever been made since the original root-making period, and he treated these primitive roots as if they were necessarily non-derivative forms. In point of fact, many of the 'roots' of the primitive tongue may be reductions from compound words comparable to 'preach' and 'cost' in English. (See ROOR.) Such primitive roots in Müller's opinion, however, are ultimate facts, the nuclei in a chaos of interjectional or imitative sounds. Whitney upheld the view that language was composed of a body of conventional signs originally of depictive character of any sort, onomatopoeic or not. In one respect only was there an advance in Müller's system on Schleicher. He accepted the 'physical science' view of language, but he rejected the notion of a primitive Indo-European language from which Sanskrit, Greek, Latin, Germanic, Slavonic, and Celtic were derived, though even here he spoke of the mother-language of the whole family. At the same time he argued that where in two dialectic forms of one word there are two different consonantal sounds they must go back to an indistinct pre-ethnic consonant capable of developing into either, which is, in the premises, an impossible assumption. It is remarkable that German scholarship added little to the discussion of these fundamental questions. An exception, however, must be made in favor of Paul, whose *Prinzipien* (1880) discussed at length and acutely the causes leading to phonetic and morphologic changes. On the other hand, all the great discoveries of comparative philology have been made by Continental scholars.

THE FIELD OF INVESTIGATION. Turning now from this historical outline of the growth of the science of philology to the subject-matter of the science, it will be necessary first to explain the field of investigation. Comparative philology as applied to the Indo-European languages (q.v.) first demarcates those languages from others. The Indo-European family constitutes a single group, separated both by vocabulary and by structure from other groups of languages. Whether the Indo-European group had at any time a common origin with other groups passes human knowledge. Many scholars (Ascoli, Abel, and others) have made abortive attempts to connect Indo-European forms with Semitic, Mongolian, and Egyptian forms, but nothing cogent has been produced to show that there is any radical affinity between them, though there has often been connection. The name Indo-European is only one of many, but at present the usual one, to designate the group called in German quite as often Indo-Germanic, and in English frequently Aryan. The last name is one often used by German scholars to designate the narrower group of Indo-Iranian. The members of the Indo-European group are the sub-groups known as Indie, Iranic, Anatolic, Hellenic, Celtic, Teutonic, Balto-Slavic. Some scholars add Albanian as a separate sub-group and some particularize Armenian as a subdivision on a par with Hellenic (see below). These sub-groups include a great number of languages and dialects, various in themselves and in some cases intricately combined. The chief elements making each group are:

INDIC. Sanskrit and the pre-Sanskrit Vedic language. The former name is often made to cover both divisions, but, like English in relation to Anglo-Saxon, though conveniently used, it is

not accurate. There was no Sanskrit language till after the Vedic period. Whether Sanskrit is derived from the Vedic may be doubted. It is closely connected with that earlier language, but it is quite possible that the two are dialectic variations from the start. Evidence given by the Linguistic Survey of India seems to show that there were two main Aryan invasions of India, entering by two different routes and at different times; that those speaking the Vedic language were the first comers, afterwards pressed to the wall by the ancestors of those who in course of time spoke what we call Sanskrit. Opposed to Sanskrit is Prakrit (q.v.), a general term for various dialects recognized at an early date as being not Sanskrit and yet not foreign. The language of Hinayana Buddhism, Pali (q.v.), was one of these patois. It is closely related to the Vedic language, and may be as old. Corresponding to the patois Prakrit dialects of antiquity are the modern provincial dialects, Bengali, Panjabi, etc., reflecting, however, more or less the effect of Sanskrit. A European offshoot of this division is the Gypsy language of Europe, many of whose words (verbal roots) are still identical with those of Sanskrit. (See GYPSIES.) The oldest literary remains of this group are from B.C. 1000 to 1200, though some scholars assign a much greater antiquity to the Vedas, the earliest Indic literature.

IRANIC. This group, the name of which is derived from Iran (Eran), the great plateau including Persia, Afghanistan, and Baluchistan, can be traced from quarters contiguous with the Indic group, and is closely connected with the latter. In fact, Indie and Iranic (Aryan in the narrower sense) are both dialects of the same language rather than separate languages. Especially is this true of the Old Bactrian (Avestan or Zend) division of Iranic (see AVESTA), the sacred literature of which extends back to about the seventh century B.C. Opposed to this division is the Old Persian (q.v.), sometimes called the Western dialect in antithesis to Avestan as the Eastern. Old Persian is the language of the euneiform inscriptions of the Persian kings, and this alone survived as a spoken language, being gradually modified into Pahlavi (q.v.) and New Persian. See PERSIAN LANGUAGE.

ANATOLIC. This group comprises Armenian (which was formerly regarded as Iranic and is now sometimes accorded a separate division), Phrygian (q.v.), and Scythian, and until lately was supposed to be represented by Lycian and Carian also. Later investigations, however, have shown that the two latter do not belong to the Indo-European group, and Scythian applies only to such remnants of Indo-European origin as are represented by some of the names of nomads in Southern Russia and on the border of Asia Minor. As such the division is maintained by Fick, but it rests on very doubtful evidence. The oldest literature is of the fourth century, unless the recently (1902) interpreted 'Arzawa' language assigned to Cappadocia be regarded as Indo-European (c.1400 B.C.).

HELLENIC. This comprises all the old Greek dialects, Ionic, Doric, etc.; Albanian, a mixture of Greek and foreign elements; also the modern dialects of Greece. (See GREEK LANGUAGE.) The literature goes back to about B.C. 1000.

ITALIC. This division includes Latin, Umbrian, Oscan, and other minor dialects; modern dialects,

in part primitive, in part due to foreign elements, Italian, Provençal, French, Spanish, Portuguese, Ruman, etc., called in general Romance. The literature goes back to the third century B.C. (inscriptions still older). See LATIN LANGUAGE; ITALIC DIALECTS; ROMANCE LANGUAGES.

CELTIC. This group comprises (1) Cymric (Welsh, Breton, Cornish); (2) Gadhelic (Erse, Manx, Gaelic). The literature can be traced to the eighth century A.D. See CELTIC LANGUAGES.

TEUTONIC. Originally Gothic (see GOTHIC LANGUAGE) and non-Gothic were the only divisions. These subsequently, on the basis of one euphonic change, were differentiated into Low and High German. The old divisions, still recognized by many scholars, are: (1) High German (Old, Middle, New); (2) Low German (Gothic, Saxon, Dutch, Frisian); (3) Scandinavian (Norse, Icelandic, Swedish, Danish). Gothic literature (translations of the New Testament) is of the fourth century A.D., but linguistic forms cited by Roman writers are earlier. See TEUTONIC LANGUAGES.

BALTO-SLAVIC (SLAVONIC). It is customary to unite these languages, which, however, stand as far apart as do Indo-Iranic. The Baltic (or Lettic) division, embracing the Old Prussian (q.v.), Lithuanian (q.v.), and Lettic (q.v.), the last-named spoken in Courland and Livonia, forms a unit over against the Slavic division (see SLAVIC LANGUAGES), which is divided into a large number of dialects incapable of being subdivided into different groups, though one division into Eastern, (South) Eastern, and Western, and another into two subdivisions are sometimes made. But phonetics and morphology together prevent such classifications except as a matter of convenience, all the dialects being more or less related, but not in such a way as to show that any of them formed sub-groups. A common and convenient geographical distribution is into the Western group, Polabian (formerly spoken in North Germany), Polish, Sorbian (represented by the Wendish spoken in Lusatia), Czechish (spoken in Bohemia, Moravia, etc.), and the (South) Eastern group, Servian, Croatian, Slovenian, Bulgarian, on the one hand, and Russian, on the other. Literary fragments go back to the eighth century. In the (narrower) Baltic division, however, a catechism of the sixteenth century represents the oldest known form of the dialect.

INNER RELATION. Having thus sketched the geography of these parts of the Indo-European languages, we must next inquire whether any of these parts hold to each other especially close relations. Much that here seems obvious shows itself to be misleading. Thus Latin is often regarded as standing in a peculiarly close relationship to Greek. In point of fact, however, while the Greek and Latin literatures are closely connected, there is no special kinship of the two languages. To detail all the groupings by subdivisions that have been urged by different scholars would take too much space, but the most practical historical differentiation is based on the varying treatment of the gutturals and vowels. In Hellenic, Italic, Celtic, and Teutonic, *k* and *q* represent the *ś* and *k* of the Eastern languages. The Sanskrit tenuis is preserved in the Western group, but the media and aspirate are modified to *j* and *h* (confused with the palatal evolution). The Western group had a pure *k* instead of the *ś*-

series, and *q*-sounds (tending to become labials) instead of the *k*-series. Examples of the *k*-series are Hellenic *ἐ-κατόν*, Italic *centum*, but Indic *śatam*; *δχος*, wagon, but Avestan *vazaiti*; of the *q*-series, Italic *quod*, Indic *kad*. In vocalism the Eastern group has a simpler series than the Western. Now between these extremes lies the Balto-Slavic (and in part the Anatolic) system, which agrees with the Eastern group in having the *ś* and *k* series (as against the *k* and *q* series), but with the Western group in its more varied vocalism. There are no divisions of the languages which are of so marked a character as these of the '*śatam*' and '*centum*' divisions. Latin stands near to Celtic in some forms (future and passive), but near to Sanskrit in others (e.g. the ablative). So in other aspects of morphology, Balto-Slavic, Sanskrit, and Greek are akin, while in others they stand apart, and such resemblances and divergencies are found among the other languages as well. What the inner relation may have been cannot be more nearly established by a comparison of forms, still less of vocabulary, and it seems safest to establish as sub-groups only Eastern (Middle) and Western divisions. That Indic and Iranian lie so closely together may be due rather to their closer synchronism than to an originally greater similitude.

Before proceeding with the discussion of the inner relationship of these groups as shown by sounds, forms, and syntax, it is necessary to revert to the question of the primitive language, which, as was shown above, occupied so large a share of the attention of Schleicher. Since his day the problem has assumed a new form which may be studied under two aspects, geographical and dialectal. It was the opinion of the older Sanskritists that the earliest home of the Indo-Europeans was on the Pamir tablelands. Other sites have been assumed, the plains of Europe, Scandinavia, and many other centres. But on the basis of a comparison of the common vocabulary of all the languages and the state of culture represented by it, present opinion, induced largely by the results of Schrader's studies, inclines to the belief that the original home of the Indo-Europeans was on the plains north of the Carpathian Mountains. A very important contribution to the question was made by Schmidt, who tried to show that the duodecimal system of the Indo-Europeans was derived from Semitic sources. The discovery in 1902 of the Arzawa Letters (see above) would strengthen the belief in an early intercommunication between Indo-Europeans and Semites. These data, if accepted, would show that the Indo-Europeans at a very early period were near neighbors of the Semites, and perhaps in close communication with them. Further, it is known that trade communication between the north of Europe and the southeast, possibly Semitic, took place at an early date, and, finally, it is scarcely to be doubted that Indo-European language and Indo-European race are not terms implying an identity of race and language. In short, language proves nothing with regard to race. This truth leads to a clearer insight in regard to the 'parent speech.' Instead of imagining that there was a racial unity once marked by linguistic unity, we must inquire whether, in giving up racial unity as shown by language, we must not also renounce all attempts to establish a former linguistic unity. The answer will un-

doubtedly be an affirmative, and it is rendered more probable by all that we know of modern languages. The German dialects, for example, show no trace of ever having been identical in form. Still more striking is the illustration given by Slavic as compared with Baltic. In a word, there was no parent speech of the Indo-Europeans; but there were always related dialects. (See DIALECTS.) Thus the smallest dialect, geographically speaking, of Greece or Rome, may preserve forms as ancient as any other. The idea of a language-unity splitting up into dialects and these again into sub-dialects is a false conception. Co-dialectic forms is the only right expression. All efforts made to trace out a parent speech are based largely on doubtful data of the use of words regarded as original, although we do not know whether the words may not have been borrowed. All reconstructions of the parent speech, whether in the form of literature (such as Schleierher indulged in) or in the form of reconstructed hypothetical words, which are supposed to represent the sound of the *Ur-sprache* and are constantly employed in our comparative grammars, are pure fictions of the imagination, and are not to be regarded as representing an actual prehistoric condition of the language. We know the Indo-European languages only in dialectic form, as spoken by various races over a wide area. The dialects are divarications from each other, not, so far as we know, from any unitary parent speech. A universal parent speech is an historical possibility, but an Indo-European parent speech is merely a convenient hypothesis, which, however, leaves more to be explained than it explains, and may best be discarded, however pleasing it be to the mind which prefers unity.

PHONOLOGY. The regular interchange of certain sounds in the different languages of the Indo-European group was generally postulated at an early period without the later insistence on the necessity of regularity. At first it seemed as if there were exceptions which could not be explained by any law. The sounds first compared were consonantal, as these seemed most regular. Their correspondence in certain of the Indo-European languages was formulated by what is known as Grimm's law (q.v.).

The vowel-system took longer to explain and the consonantal system required modification. In the case of the vowels, apart from the determination of the long disputed point whether the *a*, *ε*, *ο* of the Greek, or their equivalents in one *a*-sound, as in Sanskrit, represented the older state, the vowel-system was seen to be more regular as soon as the primitive existence of sonant nasals and liquids was recognized. The chief modifications of Grimm's law and further contributory laws were established during the last quarter of the nineteenth century. At the same time was raised the question in regard to the original vowel-form of roots and that of its changes in *Ablaut* or modified vowels and diphthongs.

The priority of the Western *a*, *e*, *o*, as compared with the Asiatic monotone *a*, was proved by Amelung and Brugmann at about the same time. Next was shown the existence of an Indo-European *e*, that is of a real palatal vowel, in Sanskrit itself. This was proved by Collitz, and independently by Verner, through demonstrating that when a Sanskrit *a* (= *e*) follows a guttural it palatalizes it and hence must itself be palatal.

Thus Sanskrit *ca* = *τε*, *que*. Osthoff and Brugmann, again, pointed out the existence in Greek of the Sanskrit *l* and *r* vowels, as shown e.g. in *παρρῶσι* (= Sk. *pitṛṣu*), *ἔδρακον*, etc. Then, as opposed to the view of the Hindu grammarians and early European scholars, it was shown that in the series *i*, *e*, *ai*, the simple vowel is no more radical than is the *guna* form, *e*, *ai*, or, in other words, we cannot speak of the stem in *φένγω*, to take an analogons case, as being less original than that in *ἔφνγω*.

The chief modification of Grimm's law was made in 1875 by the complementary law of accent, which goes by the name of Verner's law (q.v.).

In discussing consonantism, the designations of other than the guttural series are self-explanatory, but in the guttural series there is great confusion of nomenclature. Thus the Indo-European languages had palatal sounds, *c*, *j*; dentals, *t*, *d*; labials, *p*, *b*, both aspirated and non-aspirated. So they had aspirated and non-aspirated, surd and sonant, gutturals, *k*, *g* (*kh*, *gh*). But these latter, being, as explained above, of twofold form, have different designations. There are two series, the palatal and non-palatal guttural series. These are sometimes distinguished as palatal and velar, but the former is also called the *ś*-series, and even the *k*-series; while the latter is called the *g*-series and also the *k*-series. The velar *k*-series was from the beginning distinguished from the palatal guttural by being a sort of back guttural, with a tendency to develop a half-vowel sound (*q^u* or *k^u*), which was lost in special languages. The two sounds either united or the guttural became more labialized, Sanskrit *ka*, Latin *quo*, Gothic *hva*, a tendency that reached an extreme in Greek, where this guttural is often represented by a labial, as in *πo* (also before nasals and liquids), though sometimes dentalized, as in *τε* (before *ι*, *ε*), while sometimes coinciding with *k* (*κῶς*). Besides gutturals and palatals, the Indo-European group possessed the consonantism just described, but it was defective in friatives and spirants (e.g. *f*, English *th*, *z*). Peculiar to the older language are the aspirated sonants retained in the Indo-Iranic group beside aspirated surds, as well as the modified nasals and sibilants, *n*, *s*, including *ñ*, the final half-nasal, and final half-sibilant. As already explained, Indo-European had as half-vowels *y*, *v*, *l*, *r*. Lingual sounds (found in Sanskrit) appear to be borrowed from the Dravidians.

Before passing on to the subject of morphology it will be necessary to speak of one of the most important topics discussed, though not definitively settled, in the last few years. Verner showed that accent or stress influenced the character of consonants according to the accentuation of the syllable. The effect of stress, however, as already explained, is also patent as regards the vowel, which, as in *οἶδο*, *ἴδμεν* (originally *ἴδμες*), shifts with the accent. But of late it has been shown that another very important law of accentuation has been at work in determining the form of stems. Fick and Möller have emphasized the importance of pitch, that is, musical accent, as contrasted with stress accent. They show that there is a certain relation between the palatal vowel and a high pitch, and a guttural vowel and a low pitch, a relation explicable on physiological grounds; the action of the vocal or-

gans naturally associating the high pitch with the palatal *e* and the low pitch with the guttural *o*. Thus there is a natural connection between the accent or non-accent and the form of the two vowels in λέγω, the *e*-vowel having the high pitch, the *o*-vowel having the low pitch. This matter has not yet been thoroughly investigated, and there are many phenomena not yet explained by it. For example, in λόγος the low pitch has the stress. But at all events, accent is evidently a factor which will, when properly understood, explain much in stem-formation.

MORPHOLOGY. This studies change of form and the cause of change. The chief factors tending to change the form of words are 'phonetic degeneration,' as it used to be called, or phonetic variation and growth, due partly to individual peculiarities, but more to the attrition of speech, force of expression, the law of least resistance, and the interaction of the individual and his environment. Change of stress and change of pitch and the substitution of stressed accent for pitch affect the form as well as the accent of words. Analogy (q.v.), especially false analogy, causes changes, in the endings particularly, and the growth or change of function in one class of words is liable seriously to affect the form and even the existence of words of another class. Imitation due to association may be conscious or unconscious. Complete changes in the pronunciation of a vowel may occur over a wide area in a short time and then remain, or as suddenly disappear. Most of these changes of form are the result of a long series of gradual minute alterations, intervening in time, both in phonetics and in morphology. Difference of meaning may be mentioned last as having had effect on form, a factor more or less connected with accent. Apart from these questions of the philosophy of change, morphology has to do with the forms as presented in language, which may most conveniently be discussed under the head of roots (see Roots), stems, the forms of nouns, and the forms of verbs.

In regard to the stem-complex of root and ending, apart from a vague theory of Westphal that 'near' and 'distant' sounds have something to do with stem-formation, only one theory has been opposed to Bopp's agglutination theory. This is a profound study by Ludwig, marred only by the assumption of absolute lawlessness in phonetics. The points made are that the endings serve different purposes, a first person serves as third, a locative as a genitive, etc., and the further back we go the looser is the language. Ludwig substitutes for agglutination, therefore, the theory of adaptation. Verbal endings are not from pronouns; no personal endings existed; before the verb was the indefinite infinitive used for any person, any tense, and both imperative or indicative in meaning; suffixes acquired definite implication by a gradual adaptation of special meanings, having originally only a demonstrative sense. While containing much truth, this adaptation theory is too exaggerated to be acceptable as a working hypothesis. Another theory, that of Scherer, regards endings of stems of verbs and nouns as indicating a locative sense, while Benfey traced all endings from *anti* (believing that nouns are from verbs); but the two latter views are too fantastic to be discussed.

FORMS OF NOUNS. The same word is noun and verb in its most primitive form, as Sanskrit

dāti, 'a giving' or 'he gives.' Nouns had seven cases, perhaps more, in Indo-European. The same case had different endings, but, on the other hand, it is most likely, despite the fact that this seems to point to other cases, that, had such cases existed, some traces would have been preserved. Different endings may gradually have become restricted in application, and, as in the case of the Greek dative, different functions may have been absorbed by one ending, tending to a loss of another ending. The seven cases have endings more or less uniform, but apart from modifications caused by the form of the stem, some cases are compounds of two case-endings and some cases show different forms according as a word is declined as noun or pronoun. The seven cases are nominative, accusative, instrumental, dative, genitive, ablative, locative. They are found in the singular, dual, and plural, but except for the nominative and accusative dual in *āu* (*dr-āu*, *duo*) the dual endings are not identical in the different languages and are omitted here. The vocative is not a case, but the bare stem in weak form. An apparent ending in the *o*-stems is only a vowel-weakening. The chief endings are:

Nom. sg., *s, m*; pl., *os (es)*, (*o*)*i*, [*ā*].

Acc. sg., *m, d*; pl., *ms, ā*.

Instr. sg., *e, a, bhī (mī)*, *na*; pl., *bhis, o-i-s*.

Dat. sg., (*ai*), *e, bhya (m)*; pl., *bhyas*.

Gen. sg., (*o*)*s, sia*; pl., *om (ām)*, *sām*.

Abl. sg., [*os*], (*a*)*t*; pl., *bhyas*.

Loc. sg., *i*; pl., *su (si)*.

The ablative is lacking in the singular, except in a few nouns and pronouns, and in the plural, borrowing the forms of the genitive singular and dative plural. The plural *os (as)* is the noun-ending in Sanskrit; *ai (oi)* the pronoun ending in Sanskrit and Oscan and the noun ending in Slavic, Greek, Latin, Celtic, and Gothic. As plural signs serve both *i* and *s*, the latter being added to the nominative, accusative, instrumental, and dative. Some endings were independent words, e.g. *i, u, a, āt*, and Sanskrit still has cases made by adding *ā* to *ē*. Adjectives have noun endings (with some restrictions). The comparative *tara* means 'farther' (also *ias, ios*). The superlative, *tata, tama*, and *ishta*, is not clear. Numerals have essentially the same form in Indo-European. *ai-ka (oīnas)*, *duā, tu, śatam-centum*, up to *Χίλιαι* = (*sa*)*hasra*, though the latter identification is doubtful, and in any case may mean 'heap,' or large number, rather than a definite thousand. The duodecimal system is clearly marked in Sanskrit higher numbers alongside of the decimal system (see above). Particles are part of the noun-system and the stems end in *ta, na, m (ā)na* in Sanskrit, Avestan, Greek, and Latin. Prepositions (adverbs) may have case-endings, e.g. *παρα-ί, παρά, πρόσσω*.

FORMS OF VERBS. The Indo-European languages had four tenses, present (imperfect), aorist, perfect, future, and four modes, indicative, subjunctive, optative, and imperative. Only the first three tenses are pure, the future being modal (will), and consequently the future is found only in the indicative, with rare (Vedic) and late (Greek) exceptions. There are two voices, active and middle, the latter serving originally as a passive as well. Secondary conjugations of the pro-ethnic period are numerous. The most clearly defined are causative, denominative, intensive, desiderative, and inchoative. Sanskrit further invented a passive class, and Latin

and Celtic had a special passive voice, while Greek and Sanskrit converted certain aorist forms into passives. There are three numbers, but the dual is weak and even in the oldest Vedic and Greek interchanges with the plural, being lost in Celtic and Latin (save for the ending *-tis*), though preserved in Gothic and Balto-Slavic. Verbal endings are primary and secondary (present and preterite); special endings occur in the perfect. Omitting the dual, these endings in Sanskrit, which has preserved them most fully, are in the active singular, 1, *mī, a;* 2, *si, tha;* 3, *ti, a;* plural, 1, *mas ma;* 2, *tha, a;* 3, *a(n)ti, us;* while the middle changes *i* to *ē* and *mas, tha,* to *mahē, dhvē,* and the preterite tenses drop the final vowel and have *mahi, dhram,* for *mahē, dhvē.* The preterites and the perfect have also certain *r*-forms, *ram, rē,* etc., like the Latin passive. The present stem is divided into many classes, of which ten are recognized by native Sanskrit grammarians. Including secondary conjugations, the Indo-European languages had in all thirty-two ways of varying the stem by infixes, suffixes, and changing the vowel of the root. Many of these verbal stems coincide with nominal stems. They appear originally to have indicated modified forms of action. The aorist stem is formed either by reduplication, like the perfect, or by inserting an *s*-element, like the future, or it may be differentiated from the present class merely by the vowel or by an ending (*βῆ, βάσκω*). The future has primary endings, but in Sanskrit may be augmented with preterite endings, making a conditional. The subjunctive and optative have different formative elements and their endings are originally the primary and secondary, respectively (see below), while the imperative has preterite endings modified, or special forms. It has no modal sign. In some classes of verbs the subjunctive form coincides with the indicative. Hence *ā,* the subjunctive modal sign, Greek *η,* is not locative, as Scherer taught, but probably due to analogy. The optative sign is *ia* when accented, *i* when unaccented, as shown by J. Schmidt; whence *i* is probably a reduction from *ia* (compare *yā,* 'go,' though this derivation is not favored by Schmidt).

As to the personal endings, with the exception of the third plural (and the dual), Delbrück thinks that they are connected with the personal pronouns, but if so they must go back to a period when they were more deictic than pronominal. The singular affixes *mī, si, ti* have been explained (not very convincingly) both as taken from the pronouns and as having originated the pronouns; but the plural *anti* is probably connected with the participle, the *i* being explained by Ascoli and Brugmann as due to analogy with *tī* (a locative in Scherer's opinion). This finite verbal form would then be analogous to *amāmini* (also a participle). The middle endings have been explained as strengthened forms. In Sanskrit the only original strongest form is *āi* (*sāi* and *tāi* being later), a still stronger form of *ē,* which lends color to this (still doubtful) suggestion. Verbal stems were originally not connected with prepositions (most of which are adverbs); hence Latin compound verbs are later than Greek and Sanskrit, and 'tmesis' in the latter is really the older form. New forms have been developed in the separate language, e.g. aorist passives, the future optative and future

infinitive in Greek; a third singular preterite aorist passive and a complete *ya*-passive in Sanskrit; *r*-passive and *bo*-future in Latin and Celtic. Greek, like Sanskrit, is older than Latin in having fuller endings, a middle voice, and an augment. The other Indo-European languages have later verbal forms. The augment may have had a short and a long form, *ε, η,* and survived in Sanskrit, Persian, and Greek, with traces in Avestan.

SYNTAX. Only the chief points can be noticed here. First, as to the syntax of nouns: The old distinction between grammatical and non-grammatical cases cannot be maintained. The nominative designates the active, the accusative the passive relation. The latter is both an object of a verb and an object of thought, *this day, me miserum,* non-verbal objectifications. With space and time the accusative is still a veiled object-case. The instrumental shows accompaniment, means, limit; the dative, 'to' or 'for'; the genitive, any adjectival relation, 'of,' 'belonging to;' the ablative, source and means, 'from,' 'by;' the locative, place or time, 'in,' 'at,' 'within.' The syntactical method of Delbrück assigns to each case a certain narrow function; as either 'in' or 'within' (but not both) to the original locative; 'to' or 'for' (but not both) to the dative, etc. But each (pure) case originally contained in itself all that is ascribed to it; the dative from the beginning was a 'to' and a 'for' case; the locative expressed both 'at,' 'in,' and 'within.' The instrumental survives in adverbial form in Greek, but the Greek dative singular is a locative. The genitive in *sia* is an adjective stem like that of the pronouns, *asmāka(m), nostrum, nostri,* which explains in part the syntax of the case. So the Latin *i*-genitive may be adjectival (preserved in other Italic dialects instead of changing to *oi* or *ei,* which would be the locative form). Other genitive syntax is explained as being due to a sort of adjective-compound effect, in that the sign *as* (*os*) is probably only a nominative affected by sentence accent. So *s* is the sign of the nominative as well as of the genitive. The ablative was probably confined at first to the singular pronoun, where it seems to be from an adverbial affix. Such syntactical growths are common, prepositions (adverbs) being affixed also to completed endings to emphasize the meaning, as *in* is added to the Italic locative, *ā* to the Avestan locative, or *i* to the Latin feminine nominative, *qua-i* (*quæ*). In the last case the meaning is probably only emphatic, just as in English *yes-sir-ee, indeed-y.* The nominative *s* has been associated with the demonstrative pronoun. The *m* of the accusative is identical with the *m* of *aham, idam, ἐγών, idem,* though what shade of meaning it may have had is as impossible to explain, as is the pseudo-ending of the German *mi-ch.* The neuter nominative in *m* has been explained as borrowed from the nominative, on the ground that neuters were originally not subjects of verbs; but this is improbable.

In verbs present tense-stem connotes durative time; the aorist, unrestricted time, either inchoative or resultant; the perfect, repeated present (inchoative or intensive); the future, modally affected future (will). The subjunctive gives the idea of the unrestricted indicative with the addition of a shall or will element (time and mode); the optative expresses

should or might; the imperative, a command. The aorist may be present or preterite in time and differs from the present-stem meaning only in its quality, since it does not express continued or durative time. Thus Sanskrit *gacchati*, present, is 'he continues a-going,' but *gāti*, aorist, is 'he goes.' The present may thus do duty for a future, as in Gothic. The verbal stem being coincident with the noun-stem, the sense of *bharati* is really 'a bearing, that' or 'he is a-bearing,' rather than 'is a bearer.' The reduplication of the perfect connects it with the reduplicated present, desiderative, and intensive forms, and in its first application it connotes present time, afterwards extended to past time, perhaps helped thereto by the pluperfect (with augment), which in Sanskrit is not so much a pluperfect as a reduplicated aorist. The tense of narrative was originally the imperfect, not the aorist. The syntax of the Greek aorist is complicated by the confusion of aorist and imperfect forms. In Sanskrit, future (will and pure future) and optative complement each other and eventually suppress the subjunctive altogether.

The subjunctive, as already stated, has originally primary, the optative secondary endings; but in Sanskrit the former has taken some secondary endings, and in Greek the latter some primary endings. These endings are significant. The optative goes with the imperative and injunctive, modes of wish and command; the subjunctive with the future, shall and may. Delbrück believes that the subjunctive originally expressed will, the optative wish. But his categorical system of syntax is unable to explain the potential sense of the optative and the future sense of the subjunctive. The subjunctive originally connoted a vague shall-will, at the pleasure of the speaker. The primitive subjunctives, *ἔδομαι*, *ero*, are, in fact, simple futures. So the optative expressed both should and might. In Latin the subjunctive is partly optative. The Homeric subjunctive is later limited to half of its functions. Sanskrit has a distinct precative optative to express wish. Here, as elsewhere in grammar, linguistic machinery of a rough sort was slowly adapted to growing needs, and many shades of meaning were expressed under one form. Vulgar English shows continually how people without discrimination get along very comfortably with the same tense and mode and ending for many situations. In regard to the imperative, which has secondary endings, it was originally used only in the present and for commands, not for prohibitions. Hence *μή* is used with the subjunctive aorist, and later with the present imperfect only as an extension. So a subordinate negative clause takes *μή*, as *ὅς μή* *ἔλθῃ*. ('shall not come'). Thence the use was extended (*εἰμή* with indicative). Some scholars claim that the optative was originally potential, for the pure optative is used with *οὐ*, not with *μή* (for wish). It is worth noticing, in connection with the Greek secondary endings, that when used without augment they may always indicate a command, as in the Sanskrit injunctive, which is an unaugmented preterite.

The determination of the meaning of cases, of tenses, and of moods does not exhaust the store of syntactical problems upon which light has been thrown by comparative philology; but these are the most important aspects and they show sufficiently what has been accomplished. The dis-

covery of new cases (instrumental and locative) in Sanskrit, not recognized in the classical languages, laid the basis for a thorough treatment of case-relations; as the discovery of the injunctive and the Vedic values of subjunctive, optative, aorist, and perfect first clarified the problems connected with the verb.

MODERN TENDENCIES. A typical example of the relation between the stages of growth in the study of philology is given by etymology (q.v.). Before Pott there was an utter want of scientific method. Pott opposed this looseness. Curtius again opposed Pott for thirty years on the ground that Pott was not strict enough. The "young grammarians" in their turn attacked Curtius because he refused to admit that phonetic law is irrefragable.

More recent studies have made etymology much stricter still. To cite a famous example, of all the parallels in the names of Greek and Hindu gods utilized by Müller in his mythological studies, only one case, Dyaus-Zeus, is now regarded as certain. On the other hand, in the question of irrefragable phonetic law, the modern tendency has been to claim that the new school went too far. Bechtel, in 1892, and since then other scholars have questioned the validity of the shibboleth of 'changeless law.' Other doubts have arisen in the last decade on other fields. Stress accent has been replaced in part by musical accent in importance. Schmidt's wave theory has been modified. Semitic influence, as shown in numbers, has been replaced by a putative Dravidian influence, but this matter is unsettled. In geography, Lycian and Carian have been definitively removed from the field of the Indo-European languages. The importance and antiquity of Pali (q.v.) has been brought to the fore. The possibility of reconstructing a 'parent language' has been rendered quite doubtful. Syntax has virtually been built up by one great German scholar, Delbrück. It was the latest task of philology. Naturally the principles thus swiftly built into a system by one man are open to revision. Signs are apparent that the categorical method hitherto employed has ceased to be useful in helping to discover the genesis of syntactical change. Delbrück himself has admitted that his results are founded chiefly on subjective impression. Other scholars question, not the value of the facts amassed by Delbrück, but their interpretation, in criticism that began with Whitney and has tacitly been accepted by Brugmann, Speyer, and other interpreters of syntactical data. In like manner the motive of phonetic change as explained by Delbrück has recently been attacked by Wundt, Meyer, and Oertel, who have respectively sought to show that phonetic change depends largely on ease (or speed), strength of expiration, and geographical environment.

But besides laying stress on new points of view of minor importance, such as haplography, philology has recently brought to the fore one principle and elevated it into the dignity of a new branch of the study under the name of semasiology (q.v.). In 1897 Bréal published his *Essai de sémasiologie*, which organized into a systematic whole, under different categories, transfers of meaning in the evolution of words. Contiguity, resemblance, and contrast were shown to cause changes of meaning. Our word 'pike' for 'road,' for example, arose from 'turn-pike road,' with a gradual reduction of the

phrase to its most characteristic element (the pike or pole which turned the stile at a toll-gate) to represent the whole.

PHIL'OMEL (Lat., *philomela*, from Gk. φιλολήλα, nightingale, from φιλῆν, *philein*, to love + μέλος, *melos*, melody). A nightingale, especially the Persian one. See NIGHTINGALE.

PHIL'OME'LA (Lat., from Gk. Φιλομήλη). In Greek mythology, a daughter of Pandion, King of Athens, and sister of Proene. In reward for assistance rendered, Pandion gave Proene as wife to Tereus, King of Thrace, who became by her father of Itys. He then dishonored Philomela, pretending that Proene was dead, and to prevent her from telling her wrong cut out her

tongue. Philomela, however, by weaving words in a robe, revealed the truth to Proene, who, to punish her husband, killed her son and served him up to Tereus. The sisters then fled, but, being pursued by Tereus, were changed into birds; Proene and Philomela to swallows or nightingales, while Tereus became a hoopoe or hawk.

PHILOMELA, THE LADY FITZWATERS' NIGHTINGALE. A romance by Robert Greene (1592). It is founded on an Italian story of jealousy, perhaps *Tito and Gisippo* in the *Decameron*. Philip charges a friend, Lutesio, to test his wife by tempting her. Though innocent, Philomela is divorced and flees to Palermo, where her repentant husband discovers her, but his joy is so great that he chokes and dies.

PHIL'OPÆ'MEN (Lat., from Gk. Φιλοποίμην, *Philopoimén*) (B.C. 252-183). The most illustrious statesman and general of Greece in the period of her decline, the great object of whose life was to establish the independence of his country on a firm and lasting basis. He was born at Megalopolis, in Arcadia, of a noble family. At an early age he lost his father, and was brought up by a wealthy citizen of Mantinea named Cleander, who secured for him a careful education. He received instruction from the academic philosophers Eodemus and Demophanes. His first experience in warfare was gained in the border raids which took place between the Arcadians and Laconians, and in B.C. 222 he with a few others defended Megalopolis against the attack of the Spartan King, Cleomenes. In the following year, when the Macedonian King Antigonos came to the assistance of the Achæans, Philopæmen joined him at the head of a band of horse, and distinguished himself in the battle of Sellasia (B.C. 221), in which the power of Sparta was completely broken. Philopæmen now went to Crete, where he lived for several years; on his return in 210 he was appointed commander of the Achæan horse, and in the expedition of 209 against Elis distinguished himself for his bravery, slaying with his own hand the Elean leader, Demophantus. In 208 he was chosen strategus or commander-in-chief of the Achæan League, a position which he held eight times in all. He at once proceeded to introduce reforms into the discipline and armor of the soldiers, and soon, by these means and by his personal influence, made the army a most effective instrument of war. In 207 he utterly defeated the Spartans under Machanidas, and at the Nemean festival which followed he was proclaimed liberator of Greece. In 201 he defeated Nabis, who had succeeded Machanidas as tyrant of Sparta, and soon afterwards made another voyage to Crete. Returning to the Peloponnesus in 194, he was appointed strategus in 192, and again defeated Nabis. Shortly after he compelled Sparta to enter the Achæan League, and when she revolted in 188 he took the town, razed the walls, and compelled her to adopt the Achæan laws. He was in his seventieth year and sick in bed when news was brought him that the Messenians had revolted from the League; he immediately left his bed and took command of the army. In the battle that ensued he was taken prisoner, and Democertes, the Messenian commander, sent him a cup of poisoned wine, which he drank. Consult: Plutarch's *Life of Philo-*

pæmen; Freeman, *History of Federal Government in Greece and Italy* (2d ed., London and New York, 1893); Mahaffy, *Alexander's Empire* (New York, 1888).

PHILOSOPHER OF FERNEY. A title given to Voltaire, from his Swiss residence.

PHILOSOPHER OF MALMESBURY. A title conferred on Thomas Hobbes, from the name of his birthplace.

PHILOSOPHER OF SANS-SOUCI, sän soo'sé'. A title applied to Frederick the Great.

PHILOSOPHER OF WIMBLEDON. A name used of John Horne Tooke, from his residence in Surrey.

PHILOSOPHER'S STONE, THE. A mysterious compound to which was attributed the power of transmuting metals into gold or silver, and the attempted making of which was the chief occupation of alchemists, at least during the Middle Ages. In reality it bore no resemblance to a stone, being more properly described as an amalgam. It was a universal panacea that was so eagerly sought, for with the function of a universal solvent it combined that of the elixir of life, a renewing influence on the body. The conception of the transmutation of metals was Oriental. The Arabs regarded metals as compounded of mercury and sulphur in varying proportions. To this was added a more philosophic conception of a common basis of all forms of matter, individual forms being due to a force separable from this. If the 'materia prima' could be dissolved from the combining forces and united with the special 'form' of gold and the combination could be controlled, then any bodies could be produced at will. Three forms of the philosopher's stone are mentioned—the great elixir, a red tincture transmuting metals into gold; the elixir vitæ, restoring youth and prolonging life; and the lesser elixir, a white tincture, changing metals into silver. The powers of the philosopher's stone appear to have been first described by Zosimus in the fifth century. Geber (q.v.) was the reputed author of the *Key of Wisdom*, a secret book on the philosopher's stone. The matter was generally shrouded in mystery and not clearly defined until the twelfth century. Salt, sulphur, and mercury, regarded as the elements of matter, were combined to produce the solvent. By the sixteenth century the formula of preparation become more definite. The 'mercury of philosophy,' combined with gold, was placed in a furnace where the gold was dissolved. After a long interval a black powder, called Saturn, was produced. A further heating produced the white tincture, or little philosopher's stone, and a hotter fire produced a red powder, the true stone. Van Helmont asserted that he had seen and handled the stone, which was sulphur-color, heavy, and brilliant as glass. Paracelsus described it as a solid of deep ruby color, transparent, flexible, and brittle as glass; Raymond Lully, as a carbuncle. After the thirteenth century a mystic and esoteric interpretation of the philosopher's stone seems to have been applied to morals, the stone bringing to the wearer wisdom and virtue, and purifying the soul.

PHILOSOPHICAL SOCIETY, AMERICAN. The oldest of American learned societies. Its official name is the American Philosophical Society,

Held at Philadelphia for Promoting Useful Knowledge. Its hall is No. 104 South Fifth Street, Philadelphia, in which are meeting and banquet rooms, an extensive and valuable library, many interesting portraits and busts, one of the latter being Houdon's Franklin, and a collection of relics, including the chair used by Jefferson while writing the Declaration of Independence. In 1893 the society celebrated the sesqui-centenary of its beginning, for on May 14, 1743, Benjamin Franklin published in Philadelphia "A Proposal for Promoting Useful Knowledge among the British Plantations in America," and though his suggestions were not acted upon immediately, he wrote on April 5, 1744, that the society had been formed and had held several meetings, with Thomas Hopkinson as president and himself as secretary. Within a few years regular meetings were discontinued, though before 1758 another society was started in Philadelphia, called the Junto, or Society for the Promotion of Useful Knowledge, which also languished until April 25, 1766, when it was revived, with thirty members, as the American Society for Promoting and Propagating Useful Knowledge. The earlier society renewed its activity in November, 1767, and the union of the two was suggested, but a year was spent in negotiation before the two became one on January 2, 1769, adopting the present name and electing Benjamin Franklin president. He held this office until his death in 1790. The second president was David Rittenhouse, the astronomer and the first director of the United States Mint, and he was succeeded by Thomas Jefferson. In 1785 John Hyacinthe de Magellan, of London, presented two hundred guineas to the society for a perpetual fund, the interest each year to be put into a gold medal, to be given to the author of the best discovery or improvement in navigation, natural history, or astronomy. The Magellanic fund has always been kept as a separate investment, and its medal is considered one of the great honors in the scientific world. Membership in the society is limited to those who are invited to join on account of their contributions to science and knowledge; consequently the honor of an election is highly prized by American scientists. In recent years the society has established a series of annual meetings, to which distinguished men of science of Europe are invited, and these assemblages have become events of international interest. The published *Transactions* of the society begin with 1771, in which year a copy was given to each member of the General Assembly of Pennsylvania, with the statement that "the volume is wholly American in composition, printing, and paper." The society also publishes *Proceedings*, beginning in 1833, issuing them in about two hundred parts, making over forty volumes.

PHILOSOPHY (Lat. *philosophia*, from Gk. φιλοσοφία, love of knowledge, from φιλεῖν, *philein*, to love + σοφία, *sophia*, wisdom, from σοφός, *sophos*, wise). A term originally used, e.g. by Socrates, to mean devotion to the pursuit of truth. In Plato it came to mean knowledge of eternal reality. Aristotle employed the term sometimes as equivalent to critical systematized knowledge, sometimes as meaning the science of ultimate reality. The Stoics considered philosophy to be the endeavor to obtain excellence

(ἀρετή, *aretē*) in knowledge and in morality; the Epicureans regarded the philosopher as the man who pursued happiness in the manner suggested by reason. In the Middle Ages philosophy came to be ancillary to theology, and in large measure the reasoned defense of divinely revealed truth. In modern times various definitions have been given, such as "rational knowledge derived from concepts as such" (Kant), "the revision of concepts" (Herbart), "the science of principles" (Ueberweg), "the totality (*Inbegriff*) of all scientific knowledge" (Paulsen), and "the reduction of the general knowledge obtained by the special sciences to a complete system" (Wundt); while some thinkers have despaired of the possibility of finding any definition that shall cover the whole field historically occupied by philosophical speculation. The conception of the task of philosophy necessarily changes with the course of time. At the beginning, before any special sciences had arisen, it was natural that the unity of knowledge should be insisted on, and that the student should ambitiously take all knowledge for his province. But the scope of philosophy has gradually grown narrower as its original domain has been encroached upon by new sciences. The failure of philosophers of the present to agree on the definition of their work is due to the fact that so much territory has been already occupied by these sciences as to leave the proper domain of philosophy in doubt. These sciences have one and all been experiential in their method. To those who believe in the existence of *a priori* knowledge, a point of departure for delimiting philosophy from science is obtained in this distinction of the inductive from the deductive. But the belief in *a priori* knowledge is less current than it was a hundred years ago, and some other differentiation of philosophy from science must be undertaken by the inductivist. Perhaps no better plan can be adopted than that based upon the specialistic character of present-day science. Each science pursues its own investigations in its own limited field, and will allow itself to be prejudiced as little as possible by what is done in other fields. But after all it is the same universe that furnishes object-matter to all the separate sciences, and one would naturally expect that all the separate knowledges gained by specialists would articulate themselves into a coherent system of knowledge. The hope to accomplish this articulation in detail would be idle; but every science has its concepts, which it uses to organize the facts in its own little field. Do all the concepts tally? Are they compatible with each other? Questions of this sort are reasonable, and an attempt to answer them forms the so-called philosophy of nature, which may be defined as the correlation and criticism of scientific concepts. Among such concepts are those of matter, energy and its conservation, atom, life, evolution, differential, point, line, etc. The philosophy of nature is without doubt the most difficult branch of philosophy, as it demands for its prosecution considerable familiarity with the leading sciences. But while it is not to be hoped that any very general treatment of the subject can be satisfactory, still more detailed work in the way of correlation and criticism of the conceptions employed in a few sciences can be reasonably expected. Such work has been done in English by Stallo in

his *Concepts and Theories of Modern Physics* (London, 1882), and by James Ward in his *Naturalism and Agnosticism* (London, 1899).

Again, all the sciences take for granted that man can know something about the universe. What is this knowledge? Is it really valid, as it claims to be? Is there any way of ascertaining its validity? A scientific treatment of these questions is called epistemology, or the theory of knowledge (q.v.), and forms a second philosophical discipline. Still again, can any light be thrown on the ultimate nature of the reality either of the external world or of the mind? This is the problem of metaphysics (q.v.). Formerly logic, psychology, and ethics were considered as branches of philosophy, but the modern tendency is to establish them as separate sciences. This is accomplished, however, only in a restricted sense. At bottom the question whether this or that discipline is a science or a branch of philosophy is of no great importance, when it is recognized that there is no fundamental difference in method between science and philosophy, the only difference being one of degree, not of kind. The more abstract any systematic knowledge is, the narrower the field it appropriates to itself; the more it neglects other subjects lying outside of that field, so much the more properly is it called a special science. On the contrary, the more comprehensive such knowledge is, the more philosophical it is; for philosophy is an attempt as far as possible to know the world as a whole.

HISTORY. The history of European philosophy is commonly divided into three main epochs, each characterized by a unique development, although at the same time the earlier periods furnish preface and starting-point for those which succeed them, so that the whole development is continuous. The first of these periods is that of ancient or Greek philosophy (q.v.). It extends from the earliest formulations of philosophic conceptions among the Ionian philosophers and continues into the Christian Era, throughout the dominance of paganism. While shared by other nations of antiquity besides the Greeks, as notably by certain Romans, Jews, and Græco-Egyptians, it received its form and lasting bent from the Greek mind, and its later influence proceeds almost exclusively from Athenian culture. The second period is that of mediæval philosophy, or scholasticism (q.v.). It had its rise in the theological speculations of the early Church Fathers, usually educated in Greek thought, and was continued and developed throughout mediæval times as the characteristic philosophy of Catholic Christianity. It had its culmination in the great synthesis of Thomas Aquinas, but has never ceased to be the traditional philosophy of the Church, and in modern times, as neo-scholasticism, is the subject of an energetic revival. During the scholastic period in Christian Europe the tradition of Greek philosophy was kept alive by the Arabs in Spain (see ARABIC LANGUAGE AND LITERATURE), among whom were many important philosophical thinkers. The third period is known as the period of modern philosophy, and is commonly dated from the Renaissance (q.v.), and more particularly from the advocacy of empirical methods of investigation by Bacon and of appeal to immediate reason or intuition by Descartes.

With the revival of learning there was also a

revival of all the important philosophical systems of antiquity. Platonism flourished in the Academy of Florence and found its most important advocate in Ficino. Neo-Platonism blended with Neo-Pythagoreanism, which was represented by Pico della Mirandola. Aristotelianism renewed its vigor in the two rival schools of Averroism and Alexandrism, and among the Protestants in Melancthon. Skepticism was defended by Montaigne, Sanchez, and Charron; eclecticism, virulent in its opposition to scholasticism, was propagated by Valla, Vives, de la Ramée, and Zwingli, while scholasticism found its champion in Suarez. Natural philosophy, a rehabilitation of one phase of Aristotle's system, but blended with Neo-Platonic mysticism, was developed by Cardano, Campanella, and especially by Bruno. Paracelsus and Böhme elaborated the mystical side of this line of thought, while Galileo and Kepler remained more true to an empirical study of nature, and formed the starting point of a mechanistic and materialistic conception of the universe. In Kepler, however, with his insistence on the harmony of the world order, we have a distinctively Pythagorean touch. Political philosophy took an entirely new start with Machiavelli, who threw aside the work of Aristotle and the authority of the Church, and worked out an anti-moral theory in which the State and civic freedom were all-important. But though the philosophers of the Renaissance thus bridged over the chasm that separated the ancient from the modern world of thought, it was reserved for Bacon and Descartes to lay the foundations of modern philosophy in empiricism on the one hand and in rationalism on the other; and the real problem of modern philosophy has been to rear a superstructure which should rest on both these foundations. As was to be expected, the foundations had first to be laid independently, and as a result we have two great modern schools, each equally one-sided, but each equally standing for a fundamental truth—the one, the truth that all secure knowledge rests on experience; the other, the truth that in all satisfactory knowledge the demands of reason are met.

Modern empiricism came to articulate expression first in Francis Bacon, who insisted upon the abandonment of the deductive, *a priori* speculation of the schoolmen, and on the necessity of studying nature without bias. Hobbes followed Bacon in urging the necessity of a philosophy of experience; but being especially interested in human nature, and yet lacking the data for an inductive study of society, he allowed himself to construct society out of imaginary isolated human beings and to palm off this fiction for fact.

Modern rationalism began with Descartes, who is often called the father of modern philosophy. He likewise emphasized the necessity of beginning anew, but, unlike Bacon, he looked to the inner nature of self-consciousness for the principles that can build up the structure and furnish the certainty of knowledge. The Cartesian system is rationalistic; the method for advancing our knowledge was thought to consist in letting the light of reason shine forth. This was accomplished by the application of mathematical method to metaphysics, with the result of bringing out the innate truths and principles of reason. In this way we become assured, so Descartes

argued, of our own existence, of the existence of God, and of that of the material universe. Descartes sharply separated mind and matter; mind is thinking, unextended substance; matter is unconscious, extended substance. Two great problems are therefore handed down to his immediate followers. What is the relation between mind and matter in general, and the soul and body in particular? And what is the relation between the soul and God? Geulinx, the founder of Occasionalism (q.v.), answers the former question by saying that God acts in the individual, intervening on each occasion, to maintain the parallel between mind and body. God is the real subject of human acts, the individual being but a nominal subject. The second problem is taken up by Malebranche, who maintains that God thinks in the individual. The individual is nothing but the mode of God's being. The mind is in God, and in Him views everything in its eternal significance. Spinoza carries out Cartesianism to its logical conclusion. Substance is that which exists independently. Hence the infinite alone, God, is true substance. Mind and matter are two attributes of the one divine substance. They are known to us as the parallel manifestations of the hidden substantial identity in God. Spinoza develops his system by pure deductive reasoning, following the procedure of geometrical demonstrations. He thus exhibits the ideal method of rationalism, which regards reason, working solely on its own inner principles, as capable of discovering the true nature of reality. The moral and physical parts of the universe follow from these principles with the same rigid necessity as the *demonstranda* of geometry follow from its axioms. Joyful resignation to this rationalistic determinism is the essence of morality. Spinozism reduces the dualism of mind and matter to a common principle and results in pantheistic monism (q.v.). Leibnitz endeavors to solve the paradox of Spinozism that unextended and extended substances are ultimately identical. As a rationalist he sides with Spinoza; as an individualist he sides with Locke. Leibnitz's substance is not that which *exists* through itself, but rather that which *acts* through itself. Reality consists of an infinite number of monads (q.v.), which are unextended, ideal activities, centres of original forces, or *formal* atoms. Each atom is self-contained and cannot be modified from without. Spinoza surrenders the reality of individuals to the principle of unity. This unity Leibnitz breaks up into a plurality of independent, self-active monads. But the multiplicity is synthesized by the Leibnitzian principle of continuity and the law of preëstablished harmony (q.v.). All the monads belong to an organized system, and each mirrors or represents the universe. The individuals are not isolated, but belong to an organic whole. God, the supreme monad, is pure activity, while finite monads are in a state of imperfect realization. They are not completely active. It is the passivity of finite monads that gives rise to confused perceptions, which cause the appearance of an extended, material world. These fundamental principles of Leibnitz's system are sacrificed by his follower, Wolff, who adopted merely the rationalistic method of his master and reduced philosophy once more to scholastic form. This was the culmination of dogmatic rationalism on the Continent.

In the meantime the empiricism begun by Bacon and the rationalism begun by Descartes became curiously intermixed in Locke's theory of knowledge. Locke supported the Baconian appeal to experience. The sole sources of our knowledge are empirical facts, since the mind has no innate ideas. All the materials of knowledge are externally impressed upon the mind, the sole activity of which consists in linking together the given ideas. Upon this sensationalistic basis, however, Locke built up a rationalistic ideal of knowledge. We attain certainty in our intuitive knowledge of the existence of the self, and in the demonstrative knowledge of the existence of God, and of mathematical and moral truths as well. Our knowledge of the external world, being dependent upon sense-perception, reaches only the level of probability. In this, Locke violated his own fundamental principle that our knowledge extends no further than our sensationally given ideas, and that truth consists in the agreement of ideas among themselves, not in their correspondence with things or external reality. Berkeley took Locke's definition of knowledge in a strict sense, and insisted that we never get beyond the circle of our own ideas. We know nothing about the agreement of our subjective ideas with external things. All knowledge, he contended, is purely individual, and all ideas are merely particular. The mistaken belief in the existence of self is due to the confusion of taking an abstract or general name as representative of a real thing. The reality of sense-objects consists in their being perceived. The assumption of an object apart from the idea is as useless as its existence would be. Ideas signify nothing but modifications of the conscious subject. Hume carried empiricism to its inevitable logical consequence. There is nothing knowable, he argued, but conscious experiences—'impressions' and their copies, 'ideas.' These we cannot transcend. They are externally connected by 'gentle forces,' called relations or associations. We cannot prove the existence of God, of the self, or of matter. All these are fictions of the imagination, and have no basis in actual experience. Thus, step by step, empiricism ends in skepticism.

Kant, the founder of the critical philosophy, consciously and critically attempted what Locke had naïvely achieved, the arbitration of the controversy between empiricism and rationalism. His decision was that rationalism is right in its determination of scientific method; empiricism, in limiting scientific knowledge to the sphere of possible experience or phenomena. Knowledge, he maintained, is a joint product of two factors, one furnished by the conscious subject, the other given in the raw material of sensation. The former is *a priori*; it antedates experience and is the condition which makes experience possible. The latter is *a posteriori*, given from without. The *a priori* would be devoid of content without the sensible material; the *a posteriori* would be nothing at all were it not shaped and transfigured in the mold of consciousness. Theoretical reason may not transcend the bounded domain of experience, but practical reason asserts the necessity of the belief in a world of transcendent reality, in which the moral order is the natural law. God, freedom, and immortality, though undemonstrable, are the necessary postulates of our moral being. Thus reason gives way to

faith. Fichte, starting from a Kantian basis, objected to Kant's failure to show how the *a priori* principles of consciousness are necessarily involved in the nature of consciousness, as well as to the Kantian separation of the phenomenal world and the real world of things-in-themselves. By exhibiting the process in which consciousness unfolds itself, we see that the phenomenal world is meaningless unless organically connected with its intelligible essence. Knowledge is neither in whole (Hume) nor in part (Kant) the product of sensation. It is the creation of the ego. Voluntary selves freely choose to assert themselves and thus construct their whole organized world. The moral law is the prior condition of all we theoretically know, and the outer world exists simply for the sake of our moral self-realization. The speculative method, the exhibition of the progressive nature of consciousness, is the only possible method, since knowing does not begin with facts passively received by the ego, but with a spontaneous act of the ego's creative energy. Jacobi also objected to the Kantian separation between the thing-in-itself and the phenomenal world. Without the thing-in-itself, he said, no one can enter the Kantian system, and with it no one can remain in that system. The only solution of this antinomy was to exalt faith, to which even Kant had recourse, to the supreme place in philosophy. Not knowledge, but feeling, is the organon whereby we can attain certainty of reality. Thus results a philosophy of supranatural sensualism. Schelling reached much the same result, but by a different method. He regarded the world as the embodiment of intelligence, an objective fact, indeed, but one that exhibits in its progressive forms the same principle that is found in man. But the character of that absolute principle which thus manifests itself in external nature and in man cannot be apprehended by reason. Intuition alone brings us into contact with ultimate reality. In Hegel German rationalism vigorously reasserted itself: the real is the rational and the rational is the real. All reality is but a manifestation of reason. The world is a development of thought. But thought and reason are not abstractions. The word thought is used with a width of meaning that includes in it the concrete content of the world of sense organized into an all-inclusive universe. The life and stir of the universe is the life of thought. The development of this concrete thought is a dialectical development, hence philosophy must employ the dialectical method to exhibit the nature of reality. The motive force of this development is opposition and negation. Everything is what it is by virtue of what it is not; that is, by virtue of its relation to other things. These various things taken apart are self-contradictory; only when seen in their interconnection are they seen to be real. The contradictions are not annulled in their mutual relations; they are conserved, but thus conserved no longer are they contradictory. The tracing of this process of negation is the Hegelian dialectic. With the death of Hegel, Hegelianism broke up into warring schools and became utterly discounted in Germany, only to be resuscitated later in England and America in the so-called Neo-Hegelian School.

Schleiermacher took up the philosophical problem where Fichte, Schelling, and Jacobi had left

it. He agreed with Jacobi that thought cannot grasp the essence of reality; hence philosophy is not a complete science; but while it is not complete, it is ever growing and reaching out toward the goal of the identity of thought and being. This goal, however, can be reached only in religion, the communion of the finite with the infinite upon which it feels itself dependent. In Herbart and Schopenhauer there is a twofold opposition to Hegelianism; the former opposed his doctrine of real qualities to Hegel's idealism; the latter directed his pessimism (q.v.) against the idealistic estimate of the value of existence, and maintained that the real is an irrational principle of blind impulse. Beneke attempted to synthesize the results of previous philosophical activity by developing a psychological philosophy, based on inner experience. Self-consciousness reveals directly to us the psychic constitution of man; sensation is only mediate knowledge of the outer world, which must be interpreted after the analogy of psychic life. Lotze combined the Hegelian and Herbartian positions, while Hartmann aimed at a synthesis of Schopenhauer and Hegel. Among recent German thinkers the cry of "Back to Kant" is especially prominent; this Neo-Kantianism is represented by such men as Lange, Cohen, Volkelt, Riehl, and Paulsen. Another vigorous German school at present is that of the so-called immanent philosophy of Schuppe, Rehmke, and Schubert-Soldern, who deny the antithesis of idea and object, and assert an identical unitary consciousness in all beings. The immanent content of this consciousness is the world of space and time. Allied to this immanent philosophy is the empiriocriticism of Avenarius, who, like Schuppe, begins, not with the opposition of subject and object, but with the pure experience of the unsophisticated man free of all preconceived theory. In this experience the so-called object of consciousness is an integral part; and of this experience philosophy is an exact description. Materialism had a temporary revival in the middle of the nineteenth century in Germany; its champions were Vogt, R. Wagner, Moleschott, Büchner, Czolbe, and Dühring. Sometimes identified with materialism is the monism of Haeckel, who, however, is not a materialist, but an animist, holding all matter to be instinct with life; but inasmuch as the material, not the conscious, side of being is emphasized, the doctrine is closely allied to materialism. Fechner had some years before Haeckel advocated an animism, which, however, had emphasized the conscious side of being. Wundt's philosophy is related to Fechner's, inasmuch as he holds that the mechanical universe is "the outer wrapper behind which is hidden a spiritual creative activity, a striving, feeling, sensing, like that which we experience in ourselves." Holding that conation is the most fundamental essence of this activity, his view is voluntaristic.

Returning now to French philosophy, we may say that after the time of Descartes there have been no epoch-making thinkers in France except Rousseau and Comte. Deserving of mention are Bayle, the skeptic; Voltaire, more positive in his attitude and with a leaning toward mechanism; Rousseau, the political philosopher, believing with Hobbes in a state of nature preceding society, but emphasizing the social nature of man, which Hobbes had ignored; La Mettrie and

Condillac, sensualists; Rochefoucault and Helvétius, egoists; Bonnet, a rationalistic sensualist; Diderot and d'Alembert, pantheists. The last three, along with minor thinkers, are known as the Encyclopædists, because of their coöperation in the issue of the great *Encyclopédie*. During the French Revolution the predominant philosophy was sensationalism, going under the name of ideology, given it by Destutt de Tracy. Cabanis emphasized the physiological basis of sensationalism; a little later Maine de Biran, starting with the psychological fact of self-consciousness, reached a view similar to Beneke's, in which the spiritual nature of self-activity received recognition. He was thus the forerunner of spiritualism (q.v.), which was championed by Jouffroy and Royer-Collard, and had in Cousin its most prominent exponent. Spiritualism lived through the nineteenth century, being later represented by Ravaisson, Secrétan, and Vacherot. Opposed to ideology were the traditionalists, who, while reaching spiritualistic results, were hostile to the method of the spiritualists. Accepting the Catholic doctrines as unimpeachable, they emphasized the supremacy of faith above reason. Reason inaugurated the Reformation and issued in the Revolution; it is the source of nothing but evil. Faith resting on inspired authority is alone able to reach the truth. So wrote De Maistre, Frayssinons, and Bonald. But reason would not down, and turned its attention to the social nature and relations of human beings. Saint-Simon, the founder of the French Socialistic School, was not himself so much a philosopher as a reformer; he practiced rather than theorized; but he interested many speculative minds in social problems. The greatest of his disciples was Auguste Comte. Comte contended that the only true and final philosophy is positive; true philosophy is an accurate description of facts and their experienced relations. He brushed aside all pretence of knowledge of anything more ultimate than the phenomena of experience. Positivism, however, according to Comte, is only the third stage of philosophical reflection. Man's first attitude toward nature was theological; he attempted to explain phenomena by referring them to supernatural powers. Then man became metaphysical, using abstract conceptions, like force, as principles of explanation. Finally as the third stage came positivism, the insight into the futility of previous explanations, and the recognition of facts and their relations as philosophical ultimates. About the middle of the nineteenth century, in protest against Comte, a revival of Platonism occurred in certain Catholic circles; Cartuyvels, Hugouin, and Graty maintained that ideas are modes of God's essence. Positivism passed over into agnosticism in Littré, Taine, and Renan. With the development of experimental psychology a psychological philosophy has been cultivated by Ribot, Delbeuf, and Bernard. After Darwin's *Origin of Species* appeared, evolutionism was eagerly taken up by French thinkers, chief among whom have been Fouillée and Guyau. But Kantian principles maintained their ground in the philosophy of Renouvier and his followers. Laehelir attempted a combination of Kantianism and spiritualism. Against the determinism (q.v.) of positivism, psychologism, and evolutionism, Boutroux advocates a philosophy of contingency and freedom.

Since Bruno's time Italy has made little original contribution to philosophy, although she can boast of many brilliant expositors of already existing systems. Vico and Beccaria can lay the best claim to originality, both working in the realm of the philosophy of law. Genovesi, the empiricist; Galluppi, the sensationalist; Rosmini and Gioberti, objective idealists; Mamiani, a modified Platonist; Vera and Spaventa, Hegelians; Testa and Cantoni, Kantians; Villari and Dominici, positivists; and Bonavino, Thomist, deserve passing mention.

For the last two centuries Great Britain has shared with Germany the honor of having distinctive national philosophies. English thought has been predominantly empiricist and associationistic until the last half century. Hartley gave associationism (q.v.) its modern form, and James Mill applied it to all the life of mind. J. S. Mill, best known popularly by his utilitarianism (q.v.), did his greatest philosophic work in logic. True to empiricism, he introduced induction into the place it now occupies in logical theory, and yet he builded better than he knew. His empiricism did not furnish an adequate basis for his logic, and subsequent logicians, as Sigwart in Germany and Bosanquet in England, have succeeded in effecting a reconciliation between empiricism and rationalism in logic; but this they could not have done without Mill's pioneer work. Darwin's great discovery has been extremely fruitful in philosophy. Spencer has worked out an evolutionary philosophy in elaborate detail, but with a strong individualistic bias. It is, however, marred by a lack of historic perspective. Lowes represented positivism; Martineau has been the most prominent advocate of intuitionism (q.v.), applying intuitionistic principles especially to ethics and theology. Green, Bradley, and Bosanquet, under the influence of German idealism, have sought to stem the tide of empiricism. Ward, from a psychological starting-point, has likewise reached an idealistic result. Under the leadership of these men and of the two Cairds, of Scotland, English philosophy has almost left its empiricist moorings.

The typical philosophy of Scotland since the time of Hume has been intuitionism. Hutcheson may be regarded as its founder. Reid and Stewart gave it classical expression. This Scotch thought was a protest against the Lockean doctrine that knowledge is only a correspondence between ideas, and stoutly maintained that we have immediate knowledge of objective reality. Hamilton, in his natural realism, sought to reconcile intuitionism with Kantianism. The two Cairds and Stirling broke away from the intuitionistic tradition and gave Hegelianism a vogue which makes it rival intuitionism in Scotland and empiricism in England.

In America the greatest original philosopher was Jonathan Edwards, who, starting from Lockean premises, elaborated under Calvinistic influences a most uncompromising determinism (q.v.). Franklin, while not technically a philosopher, gave an impetus toward empiricism. Witherspoon and McCosh brought strong support to Scotch intuitionism, also taught by Upham and Wayland. Among the educators who early aroused interest in philosophy were Noah Porter, Mark Hopkins, and Daniel Coit Gilman. Hiecock was mildly Kantian; Bowen was

eclectic; Bowne and Ladd are Lotzeans. The Concord School of Philosophy, headed by Emerson, popularized German idealism, which has been strongly defended technically by Harris; while Royce and Dewey have given it a more independent and original statement. James is a brilliant advocate of empiricism and seeks to rescue philosophy from agnosticism by asserting the right of a will to believe in face of doubt; and George Stuart Fullerton is a keen critic, whose studies in epistemology are of special importance.

In the last century the significance of the history of philosophy has been brought out by a long line of historians, beginning with Hegel. The result is that the continuity of philosophic development, and the genuine advance made by philosophic thought, in spite of an apparently merely back-and-forth movement, have been appreciated.

PHILOSOPHY, MORAL. See **ETHICS**.

PHILOS'TRATUS (Lat., from Gk. Φιλόστρατος). The name of four sophists of the Roman Imperial period. According to Suidas the first three were all natives of the island of Lemnos. (1) The first PHILOSTRATUS lived in Nero's reign (A.D. 54-68). The only extant work of his is the dia-

logue *Nero*, a conversation between the Lemnian Menecrates and the banished philosopher Musonius Rufus on the Emperor's proposed canal across the Isthmus of Corinth and on his great cruelty.

(2) **FLAVIUS PHILOSTRATUS** flourished under Septimius Severus (A.D. 193-211) and his successors. At the request of the Empress Julia Domna, he wrote a remarkable *Life of Apollonius of Tyana*, in which he laid especial stress on the miracles ascribed to this pagan saint. The work was used later to oppose the teachings of the Christians. The same Philostratus is the author of the extant *Lives of the Sophists*, written soon after A.D. 229. (3) The third **PHILOSTRATUS**, son of Nervianus and son-in-law of Flavius Philostratus, was a young man in the reign of Caracalla (A.D. 211-217). He composed a work entitled *Imagines* (*Eikónes*), which is still extant and describes 64 paintings in Naples. (4) The last **PHILOSTRATUS** was a grandson on his mother's side of the third Philostratus. He also wrote an *Imagines*, after the manner of his grandfather's book. This work is inferior to its model, and in its present form breaks off in the description of the seventeenth painting. The *Imagines* of the third Philostratus at least have now been proved to be descriptions of actual works of art, and so are of great value to the archaeologist. The dialogue *Heroicus* probably belongs to the third sophist, while the second apparently was the author of the interesting collection of *Letters*. The standard edition of all these works is by Kayser in the Teubner Collection (2 vols., Leipzig, 1849). The *Imagines* of the third Philostratus have been separately edited by the members of the Vienna Classical Seminary (Leipzig, 1893).

PHILO'TAS (Lat., from Gk. Φιλώτας). A Macedonian general. See **PARMENION**.

PHILOXENIAN VERSION. See **BIBLE**, section on *Text of the New Testament*.

PHILOXENUS (Lat., from Gk. Φιλόξενος) (B.C. 435-380). A famous dithyrambic poet, born in Cythera. When the Spartans recaptured the island from the Athenians, probably after the Sicilian Expedition, he became a slave. Eventually he passed into the hands of the poet Melanippides, who, attracted by his talent, educated and freed him. He lived some time at the court of the elder Dionysius in Syracuse. There he forfeited the tyrant's friendship either on account of his frank criticism of his patron's verses or because of his love for a beautiful flute-player, Galatea, the mistress of Dionysius, and was imprisoned in the quarries. Philoxenus subsequently took vengeance on Dionysius by composing the most famous of his dithyrambs, *The Cyclops*, in which he represented himself as Odysseus winning from the Cyclops the affections of his sweetheart, the nymph Galatea. This was the model for Theocritus's eleventh idyl. After leaving Syracuse, Philoxenus lived at Tarentum, and later in Greece, and died at Ephesus. He wrote 24 dithyrambs in all, which were greatly admired in antiquity. Of these only insignificant fragments remain. The poem entitled *The Banquet* (*Δείπνον*), of which much is extant, is generally ascribed to this Philoxenus; but it is probably the work of a Philoxenus of Leucas. The fragments are published by Bergk, *Poetæ Lyrici Græci*, vol. iii. (Leipzig, 1882).

PHILTER, or **PHILTRE** (Lat. *philtrum*, from Gk. φίλτρον, *philtron*, φίλητρον, *philetron*, love

charm, from φίλειν, *philein*, to love). An artificial means of inspiring and securing love. A belief in such charms seems to have been generally prevalent from an early age. Among the Greeks and Romans (among the latter in the later days of the Republic, and under the emperors), love charms, and especially love potions, were in continual use. Probably certain poisonous or deleterious herbs and drugs were among their chief ingredients, to which other substances, animal as well as vegetable, are said to have been added, coupled with the employment of magic rites. Thessaly was famous for producing the most potent herbs, and her people were regarded as the most skillful practitioners of magic arts, whence the well-known *Thessala philtra* of Juvenal (vi. 610). These potions were violent and dangerous, producing madness and death, instead of merely serving the purpose for which they were intended. The use of philters seems to have been not unknown during the Middle Ages; and in the East, belief in the power of love potions has never died out.

PHINEAS (fin'é-as) **FINN**, THE IRISH MEMBER. A novel by Anthony Trollopé (1869). It is the first of a series of political tales, *Phineas Redux*, *The Prime Minister*, and *The Duke's Children*, in which Finn and most of the characters of the story reappear. The hero, a handsome young Irishman, goes to London and enters Parliament. Much of his success is due to the Standish family, particularly Lady Laura. At the close he throws up his political career, retires to Ireland, and marries his former sweetheart, Mary Flood-Jones.

PHINEUS, fin'é-üs or fin'ūs (Lat., from Gk. Φινεύς). A blind soothsayer, the son of Agenor, and King of Salmydessus in Thrace. Because of his cruelty to his children by his first wife, when his second wife accused them falsely, he was punished with blindness and was tormented by the Harpies, who seized or defiled all the food placed before him. He was delivered from the monsters by Zetes and Calais, and in return directed the Argonauts in their expedition. Other traditions represent him as being slain by Heracles or by Boreas.

PHIN'TIAS (Lat., from Gk. Φιντίας). A friend of Damon. See **DAMON** AND **PHINTIAS**.

PHIPS, or **PHIPPS**, Sir WILLIAM (1651-95). The first royal Governor of Massachusetts. He was born at a border settlement, since called Woolwich, on the Kennebec River, in Maine, and was one of a family of twenty-six children, all of the same mother. Till eighteen years of age he was employed in keeping sheep, but dissatisfied with this occupation, he became a ship-carpenter, and removed to Boston. There he learned to read and write, and also married a widow with some property. Some years later he conceived the idea of fishing up treasure stored in a Spanish galleon that had been wrecked fifty years before in the West Indies. The English Admiralty fell in with this plan and gave him command of a frigate, but after a long search he returned unsuccessful. A little later he was sent out again in a vessel provided by the Duke of Albemarle and others, and this time he found a wreck and took from it treasure to the value of about £300,000. As a reward for his success, he received as his share £16,000, the honor of knighthood, and the appointment as sheriff of New England. In

1690 he was sent by Massachusetts with a fleet of eight vessels against the French settlement of Port Royal in Acadia, and succeeded in capturing it. Later in the same year he commanded a larger expedition, consisting of 34 vessels and more than 2000 men, against Quebec. So active, however, were the French under Count Frontenac that the attempt failed, and on the way back to Boston nine of the vessels were wrecked. In 1692, through the influence of Increase Mather, the agent of the colony in England, Phips was appointed Governor of Massachusetts, under the new charter. One of his first official acts was to commission a special court for the trial of those accused of witchcraft, but some months later he suspended its sittings. As Governor he displayed many of the bluff and choleric traits of a sea captain; among other things, he cudged Brinton, the collector of the port of Boston, and caned Captain Short of the Royal Navy. In 1694 he was summoned to England to answer complaints made against him, and while there died suddenly of a malignant fever. Phips was a man of great energy and determination, but possessed no remarkable intellectual capacity; and he appears to have been strictly honest in his private dealings, though he deemed it no sin to steal from Frenchmen. There is a curious life of him in Cotton Mather's *Magnalia* (London, 1702), but more trustworthily is that by Francis Bowen in vol. vii. of the first series of Sparks's *American Biography* (New York, 1834-37). Consult, also, Hutchinson, *History of Massachusetts*; Parkman, *Count Frontenac and New France Under Louis XIV.* (Boston, 1877); and Myrand, *Sir William Phipps devant Québec* (Quebec, 1893).

PHIZ. The pseudonym of the English caricaturist and illustrator Hablot Knight Browne (q.v.).

PHLEBITIS (Neo-Lat., from Gk. φλέψ, *phleps*, vein), or **INFLAMMATION OF THE VEINS.** Although seldom an original or *idiopathic* disease, it is a frequent sequel of wounds, in which case it is termed *traumatic* phlebitis, and is not uncommon after childbirth. (See PHLEGMASIA ALBA DOLENS.) It commonly arises by the extension of an inflammation from contiguous structures, as in phlegmonous erysipelas or cellulitis, or by the plugging up of a vein by an embolus or thrombus. If severe, the disease begins with a chill or chilly sensations, and a rise in temperature. There is great tenderness and pain along the course of the affected vessel, which feels like a hard knotted cord, and rolls under the fingers. If the vessel is small the consequences of its obstruction may be of little importance, but when a large vein is affected the consequences are always dangerous, and may be fatal.

Phlebitis may terminate in one of several ways. The most favorable is by simple resolution—the clot is absorbed, the vein becomes permeable, and circulation is reestablished. In other cases organization of the clot takes place, little blood vessels growing into it, from the walls of the vein, and the latter finally becomes a fibrous cord. The circulating blood is diverted to other channels which gradually dilate to accommodate the increased flow. Again, the clot may become infected, if it is not so from the beginning, undergo purulent softening, and the pus either discharged by the formation of abscesses, or emptied into the blood current to be carried by

the general circulation to all parts of the body. These purulent particles find lodgment in the large viscera, such as the liver, spleen, kidneys, and give rise to multiple abscesses. In the liver this frequently happens from inflammation of the portal veins. This general distribution of septic material is known as *pyemia* (q.v.). An organized clot may in rare instances become calcified by the deposition in it of lime salts, and form a *phlebolite*.

The treatment of phlebitis comprises rest in bed, elevation of the part, and the local application of antiphlogistics—lead water and opium at first, hot fomentations later. If abscesses form, they must be opened and drained. In certain cases it is possible to ligate the vein above and below the clot, open the vessel, and wash out the purulent material. The internal treatment varies with the symptoms, but in general must be stimulating.

PHLEBOLITE (from Gk. φλέψ, *phleps*, vein + λίθος, *lithos*, stone). A calcareous concretion formed by the degeneration of coagulations in veins. It is not infrequently to be felt as a nodule varying in size from a pinhead to a small bean along the course of chronically inflamed veins of the lower extremity, and phlebolites have been known to attain considerable size.

PHLEBOTOMY. See BLEEDING.

PHLEGETHON, φλεγέθων (Lat., from Gk. φλεγέθων, from φλέγειν, *phlegein*, to burn). In Greek mythology, a river of the lower world, along with Acheron, Coeytus, and Styx (qq.v.). In Homer it unites with Acheron, as does Coeytus, a branch of the Styx. Later writers described its fiery torrent and scorched and desolate shores.

PHLEGMASIA ALBA DOLENS (Neo-Lat., painful white inflammation), or **MILK-LEG.** A painful general swelling of a limb, due to the obstruction of the veins; a plastic phlebitis. It is due to pressure, general disease, sepsis, or thrombosis. Milk-leg occurs principally as an affection of women in childbed, occasionally during typhoid fever. The first symptom is a rise of temperature, which may be overlooked. Pain first attracts attention, felt on the inside of the thigh, in the groin, and in the calf, of a very severe character. There may be numbness, tingling, cramps, or creeping sensations. The limb swells early from a soft œdema, the skin being white and shining, often waxy. Blue veins may stand out prominently on the posterior part of the limb. Fibrinous coagula may be detached and carried along in the circulation to some other part, as the lung, forming embolism. Paralysis of motion, disorders of sensation, and wasting of the limb may occur. The treatment consists of supporting the limb on a higher level than the trunk; punctiliously avoiding any jarring of it; maintenance of the recumbent position for at least a month; fomentations to the limb, which must be wrapped, in the intervals, in cotton; support of the heart with appropriate drugs; control of pain with analgesics and of insomnia with hypnotics. The great danger is from pulmonary embolism, which is almost invariably fatal.

PHLEGRÆAN PLAIN (Lat. *Phlegræi Campi*). A region west of Naples, embracing the volcanic plain on the Campanian coast from

Cumæ to Capua. There legend placed the scene of the combats between the gods and the giants. The Romans filled it with palatial villas, and their poets celebrated its charm and productiveness. The volcanic disturbances to which the region has been subject have left of the magnificent buildings of the Romans only confused ruins, in part submerged under the sea.

PHLEGYAS, φλεγῆϊ-ās (Lat., from Gk. φλεγῆϊας). The son of Ares, and father of Ixion and Coronis. His daughter became by Apollo the mother of Æsculapius. Phlegyas was so incensed that he set fire to the temple of the god, and for this was condemned to everlasting fear in Tartarus, where an overhanging rock constantly threatened to fall on him.

PHLOEM, phlō'ēm (from Gk. φλοιός, *phloios*, bark), or **BAST**. That portion of a vascular bundle in plants including the sieve tissue, parenchyma, and bast fibres, and in ordinary trees forming the inner bark. See **STEM**.

PHLOGISTON. See **CHEMISTRY**.

PHLOGOPITE (from Gk. φλογώψ, *phlogōps*, flaming-red, from φλόξ, *phlox*, flame + ὤψ, *ōps*, face). A magnesium mica, similar to biotite, but differing from it in composition by usually containing fluorine and less iron. It crystallizes in the monoclinic system, has a pearly lustre, and is usually of a light yellow to brown and red color. The phlogopite occurs in serpentine rocks and frequently in association with limestone or dolomite. Phlogopite often exhibits asterism, especially when seen by transmitted light, as when a candle flame is viewed through a thin sheet. This property has been shown to be due to minute needle-like inclusions arranged chiefly in the direction of the rays of the pressure figure, producing a distinct six-rayed star. Phlogopite is found in Finland, Sweden, Switzerland, and in the United States at various localities in New York, New Jersey, and also in Canada.

PHLOX (Lat., from Gk. φλόξ, sort of flower, flame, from φλέγειν, *phlegcin*, to burn; connected with Lat. *flagrare*, to burn, Skt. *bhraj*, to shine brightly). A genus of mostly tall, erect, spreading perennial herbs belonging to the order Polemoniaceæ, natives of North America. The

CULTIVATED FORM OF MOSS PINK (*Phlox subulata*).

species, nearly all of which have a wide natural distribution within the United States, have entire leaves, and generally very showy flowers either solitary or in terminal clusters. Owing to their hardiness, easy cultivation, and the size and beauty of their flowers, many hybrid varieties with single and double flowers, in many colors, forms, markings, and long period of bloom, and a few of the pure species, are grown in gardens,

being well adapted for planting on rockeries and in borders and groups. The best known annual species of this genus is *Phlox Drummondii*, a native of Texas, from which all annual phloxes now in cultivation have been derived. *Phlox pilosa* is a somewhat variable species which flowers from May to August. *Phlox reptans* is native to the Allegheny Mountains. *Phlox Stellaria* is much prized as an ornamental plant on account of its numerous white flowers. The ground or moss pink commonly grown in gardens is *Phlox subulata*. The wild sweet William (*Phlox divaricata*) has pale lilac or bluish flowers appearing in spring and early summer. All the species of phlox grow readily in ordinary rich soil; the annuals from seeds and the perennials from seeds, division of the stools, or cuttings of the stems and roots. The seeds are sown early in the spring, given gentle heat, and after the seedlings are large enough they are transplanted, hardened under glass, and later set out in the open. The stem cuttings are made in summer and placed in fine sandy soil under cold frames or in greenhouses. The root cuttings when slightly covered with soil and placed in gentle heat sprout readily. After the cuttings have rooted they may be treated like the seedlings.

PHOCÆA (Lat., from Gk. Φώκαια). The northernmost of the Ionian cities of Asia Minor, about twenty miles northwest of Smyrna. It was said to have been originally settled by Phocians. It was included in the Ionian confederacy, and was one of the most flourishing and powerful of the Asiatic Greek cities. Its sailors were famous for the daring with which they pushed their fifty-oared war-vessels (not the heavy merchant craft) into the western seas. The westernmost colony of the Phocians was in Mænaca, in Spain, and they were on close terms of friendship with Arganthonius, King of Tartessus. Their most famous colony, however, was Massilia (Marseilles). Unable to defend themselves against Harpagus, the general of Cyrus, they abandoned their city and sailed to Chios (c.540 B.C.). Part of them subsequently decided to return and accept the Persian rule, but the majority sailed to Corsica and settled in Alalia. Attacked by the Carthaginians and Etruscans, who resented Greek entrance upon these lands, they were victorious in a great naval battle, but thought it wiser to abandon their settlement and move to Southern Italy, where they founded Hyele, or Elea (Velia). Phocæa seems to have continued to exist, though it is scarcely mentioned till it was captured and plundered by the Romans in the war with Antiochus. New Phocæa was founded by some Genoese about 1420, and this spot is now occupied by a little village, Phokia, while the site of the old city is still called Palæo-Phokia.

PHOCAÏS, fōk'ā-īs. An epic poem ascribed to Homer, and said to have been composed by him in Phocæa.

PHOCAS (Lat., from Gk. Φωκᾶς, *Phōkas*) (?-610). Byzantine Emperor from 602 to 610. He was an obscure centurion in the army, which was fighting the Avars on the Danube, when in 602 the soldiers rose in rebellion against the Emperor Maurice (q.v.), and Phocas was chosen their leader. He invested Constantinople, and after the forced abdication of Maurice was chosen and crowned Emperor. His first act was to cause the

public execution of Maurice and his five sons, and throughout his reign he was notorious for his cruelty. In Europe an ignominious peace was maintained, while in Asia unsuccessful war was waged against the Persian King Khosru II. (q.v.). He gave his only child in marriage to the patrician Crispus, and the images of the couple were indiscreetly placed by some of their friends in the circus, which was a privilege of royalty only. After this Crispus no longer felt secure, and he conspired with the rebellious exarch of Africa, Heraclius, to dethrone Phocas. This was accomplished in 610, and the tyrant was tortured and beheaded.

PHOCAS, COLUMN OF. A famous column in the Roman Forum, erected in 608 by the exarch Smaragdus in honor of the Eastern Emperor Phocas, and once surmounted by a gilded statue of Phocas. The column is 54 feet in height, and is of a better style than that which prevailed at the time of its dedication. It is therefore supposed that it may have been taken from some earlier edifice, or that an already existing monument was rededicated by Smaragdus. It was covered by the accumulated rubbish of centuries till 1813, when it was unearched by the Duchess of Devonshire.

PHOCION, fō'shī-ōn (Lat., from Gk. Φωκίων, *Phokiōn*) (c.402-317 B.C.). *An Athenian general. He was of humble origin, but received a good education and studied under Plato and Xenocrates. His first public service was performed under Chabrias at Naxos in B.C. 376. About 349 he was sent into Eubœa to quell a disturbance that had been fostered in Eretria by the partisans of Philip of Macedon, and won a victory at Tamynæ. Some years later he led a body of Athenian hoplites to Megara, crushed Philip's faction there, and reestablished the long walls to Nisæa; and also again conducted a force to Eubœa, where he liberated Oreus and Eretria from Macedonian influence. In 340 he was sent to the Propontis to act against Philip, who, besides suffering a number of minor reverses, found himself forced to abandon the siege of Byzantium and Perinthus. In politics, however, Phocion was a supporter of Philip and an adversary of Demosthenes, though not from mercenary or traitorous motives. When, after the destruction of Thebes in 335, Alexander sent to Athens demanding the surrender of Demosthenes and the other leaders of the anti-Macedonian party, Phocion advised compliance with the King's wishes. The proposal was rejected by the people, and an embassy was sent to Alexander to deprecate his resentment, but not until a second embassy had been sent, at the head of which was Phocion, was the King induced to remit his terms. After the death of Antipater Phocion became implicated in the intrigues of Cassander, the rival of Polysperchon, and was forced to flee to Phocis, but was surrendered to the Athenians and by them condemned to drink the hemlock. His body was carried out of Attica into the Megarid and there burnt. Shortly after his death there was a revulsion of feeling in his favor among the Athenians. They then celebrated his funeral obsequies at the public expense, and erected a statue in his honor. Consult Plutarch's *Life of Phocion*.

PHOCIS (Lat., from Gk. Φωκίς, *Phōkís*). In ancient geography, a division of Greece, in Hellas, bordered on the west by Ozolian Locris and Doris,

on the north by Epienemidian and Opuntian Locris, on the east by Bœotia, and on the south by the Gulf of Corinth. The greater part of the country is mountainous, with Parnassus filling the central and western portion, and only a section in the northeast, through which the Bœotian Cephissus flows, is fertile. The chief town was Elateæ, which commanded the entrance into Bœotia from the north. Other towns of some importance were Daulis, Abæ, the seat of an ancient oracle, and Hyampolis, but the most conspicuous place, to which the fame of the land was chiefly due, was Delphi, whose inhabitants, however, always claimed that the control of the oracle did not belong to the Phocians. The State was a league of 22 cities, most of which were of small size. The Phocians seem to have been akin to the Dorians, though there were elements derived from earlier settlers in those regions, and there is some evidence for colonization in the southern portion from Crete and the Peloponnesus. They do not play a prominent part in the earlier history of Greece, though we hear of a desperate defense against the advance of the Thessalians, and in general they appear as enemies of the Thessalians and Bœotians and friends of the Athenians, who supported their claim to control Delphi. In B.C. 357 the Amphictyonic Council, apparently through Theban influence, imposed a heavy fine on the Phocians for cultivating some land belonging to the Delphic oracle. The Phocians resisted the sentence and were favored, but not actively assisted, by Athens and Sparta, who were at that time on bad terms with the Council and hostile to Thebes. The Phocians seized Delphi and 'borrowed' the temple treasures with which to maintain their army. For ten years the war was waged with no decisive results, though in general to the advantage of the Phocians. Even the growing power of Philip of Macedon did not check them, for while he was victorious in Thessaly, he could not pass Thermopylæ, which was held by a Phocian army and an Athenian fleet. The Peace of Philocrates (B.C. 346) between Athens and Philip left the Phocians helpless, and the sentence of the Amphictyons, which expelled them from the Council, condemned them to an enormous fine and dispersed them into small villages, thus practically removing them from future history.

PHOCYLIDES, fō-sil'ī-dēz (Lat., from Gk. Φωκυλίδης, *Phokylidēs*) (c.560 B.C.?). A Greek poet of Miletus, contemporary with Theognis. He wrote chiefly didactic poems in two or three verses of hexameters or elegiac metre, the eighteen extant fragments of which have been included in almost all of the collections of the lyric and gnomic poets. Ποιήμα νοσητικόν, the admonitory poem, in about two hundred and thirty hexameters, which has been preserved under his name, is now supposed to have been the work of an Alexandrine Jew of the first century B.C. Consult: Bergk, *Poeta Lyrici Græci* (5th ed., Leipzig, 1900 et seq.); and Bernay, *Ueber das phokylideische Gedicht* (Berlin, 1856).

PHEBE. (1) A name applied to the goddess Artemis or Diana (q.v.). (2) In Shakespeare's *As You Like It*, a fickle shepherdess who falls in love with the disguised Rosalind, but at last marries the shepherd Silvius, her former lover. (3) A New England girl of strong common sense in Hawthorne's *Marble Faun*.

PHENIX PARK. A public park of 2000 acres in Dublin, containing a granite monument in honor of Wellington. The park became famous through the assassination within its borders, on May 6, 1882, of Lord Frederick Cavendish, Chief Secretary for Ireland, and Thomas Burke, the Under Secretary.

PHENIXVILLE. A borough in Chester County, Pa., 28 miles northwest of Philadelphia; at the junction of French Creek with the Schuylkill River, and on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, F 3). It has a public library and a hospital; and is an important manufacturing centre, well known for its great iron mills, boiler works, silk mills, underwear and hosiery mills. There is also a match factory. The government is vested in a burgess, chosen triennially, and a council which elects all municipal officials excepting the school directors, who are independently chosen by popular vote. The borough owns and operates the water-works. Phoenixville was settled in 1792 and was incorporated as a borough in 1849. Population, in 1890, 8514; in 1900, 9196.

PHOLAS (Neo-Lat., from Gk. *φωλάς*, a lurking mollusk which makes holes in stones). A genus of bivalve mollusks having much roughened, file-like shells with which they excavate cavities in soft rocks, in other shells, etc., for their own occupancy. See DATE-SHELL.

PHOLUS. A centaur, son of Silenus, by whom Hercules was entertained on his journey in quest of the Erymanthian Boar. When the other centaurs were attracted to the cave of Pholus by the odor of the wine with which he regaled the hero, Hercules scattered and pursued them, but on his return found Pholus accidentally killed by one of the arrows which he had withdrawn from the body of a slain centaur, and which had dropped from his hand and stuck in his foot.

PHONAUTOGRAPH. See PHONOGRAPH.

PHONETIC LAW (Gk. *φωνητικός, ρηδνῆτικός*, relating to sound, from *φωνή, ρηδνῆ*, sound, voice; connected with *φήναι, φηναί*, Lat. *fari*, to speak, OHG. *ban*, Ger. *Bann*, AS. *bann*, Eng. *ban*). In comparative linguistics, a formula which sums up a certain phonetic correspondence or a certain number of such correspondences. The term law in this sense is, therefore, essentially different from its application in mathematics or chemistry, and approaches rather the usage of the word as it is employed in psychology. A given phonetic law, moreover, is required to be operative only under given conditions in a given dialect or dialect-group during a given period. As an example of such a law we may take the representation of the Indo-Germanic *ā* which becomes in Germanic *ō*, which remains unchanged in Gothic, Icelandic, Old Saxon, and Anglo-Saxon; as Sanskrit *bhrātar*, Greek *φράτηρ*, Latin *frāter*, 'brother,' but Gothic *brōþar*, Icelandic *brōþer*, Old Saxon *brōthar*, Anglo-Saxon *brōþor*. Further, it is a phonetic law in Old High German that such an *ō* becomes *uo*, which is changed in New High German to *ū*, so that we find corresponding to Gothic *brōþar*, Old High German *bruoder*, New High German *Bruder*. On the other hand, Indo-Germanic *ā* becomes *a* in Old Church Slavic and *ō* (written *o*) in Lithuanian, as Sanskrit *bhrātar*, 'brother,' Old Church Slavic *bratrū*, Lithuanian *brōlis*. As the science of comparative linguistics

developed, it was found that sound-changes followed certain rules. The very earliest investigators, however, seem to have paid little attention to the problem whose enunciation and discussion was destined to mark an epoch in the history of the science, the question as to the invariability of phonetic law. Yet even then it was realized that etymology (q.v.) without strict adherence to phonetic law was capricious and unscientific. The existence of such law was emphasized by the famous discovery known as Grimm's law (q.v.), which was in its turn supplemented and accentuated anew by the enunciation of Grassmann's law (q.v.), Verner's law (q.v.), and the palatal law, which postulated the existence of *e* in Pre-Indo-Germanic. In 1876 the logical result of phonetic investigations up to that time was given by Leskien, when he stated the theorem that phonetic laws know no exceptions. This was the keynote of the neo-grammarians movement. (See PHILOLOGY.) Osthoff and Brugmann two years later stated the principle in its definite form as follows: "All sound-change, in so far as it operates mechanically, is carried out according to invariable laws." By this modification of Leskien's statement the necessary scope was given for analogy (q.v.) in controverting the action of the laws. Exceptions were, therefore, only apparent, not real, and they were to be explained either by the operation of analogy or as the results of laws yet undiscovered. This latter point had already been emphasized by Leskien, as Whitney had laid stress on the importance of analogy in explanation of many difficult linguistic phenomena. The point at issue was unfortunately shifted, and the gulf between the old and new schools of grammarians widened almost hopelessly. The contention became not the nature of phonetic law, wherein all might, it would seem, be in harmony, but whether the laws were invariable or not, a problem which is yet unsolved. Without going into the details of the long discussions which followed after 1878, where Georg Curtius and Brugmann were the protagonists for the old and new schools respectively, it may be said that the net result has been a distinct gain for the neo-grammarians movement. Phonological and etymological investigation at present tacitly accepts the invariability of phonetic law. At the same time, it is not as rigidly bound by dogmatic adherence to this principle as was the case when the enthusiasm of its novelty was potent. The influence of the doctrine has, then, been most beneficial in enforcing accuracy in the application of the laws, and compelling exact and full explanation of any deviation, however slight, from their normal action. On the other hand, sufficient attention has not yet been devoted to the explanation of the laws themselves. Why, for instance, to revert to the example already given, does Indo-Germanic *ā* become *ō* in certain languages, *a* in others, and in others still remain unchanged? Phonetic changes, instead of being absolutely invariable, are only relatively uniform and obey only general tendencies. These tendencies are governed to a large extent by physiological requirements, and further by psychological processes, especially the associative faculties of analogy, imitation, and the like. Initially the changes are individualistic. If the phonetic change in question is physiologically possible and pleasing to a speech-community, however small, it may be adopted imitatively, and may then be extended analogi-

cally, and being accepted by a widening range of speakers, it may develop into a general tendency, become relatively uniform, and thus be made a phonetic law. These conclusions are confirmed by the study of living, spoken dialects, where the artificial uniformity of script does not mislead the investigator, as is too often the case with languages which have been preserved only in literary forms.

See GRASSMANN'S LAW; GRIMM'S LAW; PHILOLOGY; PHONETICS; VERNER'S LAW.

PHONETICS. In its broadest sense, a study of the whole range of sounds, articulate, musical, and otherwise. It is, however, usually confined to the articulate sounds of human speech. Even in this restricted sense, it is still broad enough to include the subject of the purely acoustic or mechanical side and the anthropological or philological side. It may discuss simply the vibrations that cause any particular sensation on the human ear, or it may include an investigation of the manner and causes of the change of one articulate sound in one language at one time, into another sound in another language or at another epoch. In the first case it should consider the mechanism and methods by which the sounds are produced, and also the way in which they are made effective in the ear, and impress the brain.

The question of the variations of articulate sounds and of the symbols which from time to time may be used to represent them belongs to the sphere of comparative philology (q.v.), and is not, therefore, discussed in this article.

Confining the attention to the physics of phonetics, the subject naturally falls under three heads, or questions: What is tone quality, or the mechanical difference between two sounds? How are sounds produced in the human voice? and How are they perceived in the ear? The divisions may best be treated in the order given.

One sound differs from another in three factors, pitch, intensity, and quality. (See SOUND.) The pitch and intensity, or loudness, are of but little importance in this connection. The controlling factor is the quality. In articulation the sounds are divided into two broad classes: the vowel sounds, or those which are maintained in more or less uniform quality for an appreciable length of time; and the consonants, or those sounds which are more essentially a peculiar stopping or starting of a vowel sound, and which are apt to form the transition from one vowel to another, by some one of an infinite variety of ways.

Taking up the discussion of the vowel sounds first as being the simpler case, it is evident that these sounds, which last with a uniform character for an appreciable fraction of a second, or at least may be so prolonged, must depend for their distinguishing peculiarities upon the same factors as any other sound. As the pitch of a sound depends upon the length of the wave, and the intensity upon the height of the wave, so

does the quality of the sound depend upon the shape of the wave. It has been demonstrated that any wave motion, no matter how complex, may be considered as made up of a series of simple waves of differing lengths and heights. Therefore, any quality of sound, no matter how complex, is made up of simple components, differing in pitch and intensity. By a simple sound is meant one in which the vibrating particles move in a simple harmonic motion, similar, for example, to that executed by a clock pendulum. When a violinist plays a particular note, it differs from the same note on the organ or the piano or the wind instruments only in the relative number, intensity, and pitch of the 'partials' or 'overtones' which accompany the fundamental, or 'pitch-tone.' In a manner entirely analogous the maintained sounds of the human voice differ one from another, when the same fundamental tone is being produced, only in the relative number, pitch, and intensity of the accompanying partials. It is believed by some that the 'phase-relation' of the components also affects the quality of the sound, but this is still an open question and certainly does not affect the case of articulation.

The question, then, is to determine just what are the particular combinations of elements which form the various vowel sounds. In the first place, it has been shown conclusively that the same relative components will not produce the same vowel sounds on different pitches. For example, a certain combination, bearing a definite relation to a fundamental of 256 vibrations per second, will produce a certain vowel quality, but if the rates of all these components are raised by the same interval of a fifth, the vowel quality will be quite different. In other words, that combination which is recognized as giving a perfectly satisfactory *a*, as in *father*, on a pitch of middle *c*, is entirely different from that which is similarly recognized on a pitch an octave higher.

There are two conceptions at present as to what constitutes the essential characteristic of a particular vowel sound. Some hold that each vowel sound always contains in its complex a certain characteristic tone component of definite pitch, and that the presence of this element makes that vowel. For example, *a*, as in *father*, has its essential vowel tone, and *ee*, as in *meet*, would have a different tone. This theory holds that the pitch of the characteristic elements is constant, irrespective of the pitch of the fundamental, or main tone. Others believe that there is no difference in the question of tone quality in vowels from the same question as applied to any tone. Under this conception there would be no essential component, but all would be essential and the total would be characteristic. This would mean that the difference between *o* and *a* pronounced on treble *c* is of exactly the same character as that between the two sounds when that note is played upon a flute and upon a violin. In other words, vowel quality is no different from tone quality.

The actual solution of this question is enormously complicated by the fact that habit allows the greatest possible variation in what may still be called a particular vowel. For example, the *a* in different individuals may differ more radically than the *a* and *o* in the same individual.

Helmholtz seems to hold to both theories, and gives the following as the pitches of the characteristic tones of the vowels: $U = 175$; $O =$

466; A = 932; Å = 1568; Em = 1976; I = 2349. In like manner he gives the composition of those vowel sounds as made up of a characteristic combination of overtones, as follows:

VOWEL	1	2	3	4	5	6	7	8
U.....	f	pp	pp
O.....	mf	p	p	f	p
Ä (as o in not).....	p	p	p	p	ff	ff	ff	ff
A.....	p	pp	p	f
E.....	p	pp	f	p	p	p	p	p

The letters *p*, *pp*, *f*, *ff*, and *mf* have the usual musical significance.

Nevertheless the greatest difference of opinion exists as to the exact pitch of the characteristic tone, and also as to the particular combination of partials which form the particular vowel sounds. In general it seems well established that in the sound of *a*, as in *father*, the complex consists of the fundamental and the first eight or ten overtones with intensities decreasing as they rise in pitch. *E*, as in *meet*, has not the higher overtones, and is characterized by a relative strengthening of the third and fourth in the series. *O*, as in *moat*, has number four rather strong; and finally *U*, as *oo* in *boot*, is little if anything besides the fundamental and a little of the first overtone. It is to be understood that these overtones are in the series present in a string, or an open pipe, i.e. the rates of vibration of the fundamental and overtones are in the ratio of 1 to 2, 3, 4, 5, etc.

The question of the exact composition of any vowel on any pitch cannot be definitely and finally determined, for the simple reason that the character of the sound differs with every individual, and no one can be said to be right and all the others incorrect. General conclusions can be stated or specific analyses in particular cases.

As to the quality of the sounds in the pronunciation of the consonants little can be said at present, as the case is much more complex than that of the vowels. On the one hand, the quality is rapidly changing from instant to instant, thus offering new and especial difficulties to the analyst; and on the other hand, the simple more or less musical tones are often accompanied by a number of irregular noises like the hiss, the aspirate, etc. There are also the peculiar methods of stopping and starting the sounds, as in *p*, *b*, *d*, *g*, etc., in initials or finals. A class exists where a neutral sound is produced in the larynx, and formed into *m*, or *n*, or *th*, etc., according to the way in which the air is permitted to escape, by the nose or mouth.

Thus far no rigid analysis of the consonants has been possible, although the individual variations may be less than in the vowels.

The second branch of the subject is the apparatus and method of production of human articulate sounds. This function is performed by the joint action of the lungs, larynx, mouth, and nose. The lungs are simply the wind box, and serve to supply the air to actuate the vocal cords and produce the various sounds; they supply the raw material, and are the source of energy.

In the larynx (q.v.) is to be found the original source of all the sustained sounds that bear any resemblance to musical tones. Whisperings, hisses, aspirates, etc., are formed independent of the larynx. In the larynx is to be found a pair

of cords or membranes, which may be so drawn together over the top of the windpipe that they practically close it. If air from the lungs is forced against the cords under the above condi-

tions, they are set into vibration and produce a sound. The pitch of this sound is regulated by the length, weight, and tension of these cords, there being present in the larynx sets of muscles for the involuntary control of these three factors which determine the pitch of a vibrating cord. Confining the attention again to the vowel sounds, it may be said that the function of the larynx is to produce a sound which can be molded into any one of the vowels, and that its action is not determinative as to which vowel shall be produced. Articulation is not performed by the larynx, but by the agencies between it and the outer air. The particular variation of tone that is produced by an individual depends upon the cavities of the mouth and nose, the position of the various movable parts, as the tongue and palate, and the size and shape of the opening at the teeth or lips. In the flute and clarinet it is the number and location of the openings which determine the pitch to a large extent, but in the human voice it is the larynx which determines the pitch of the fundamental, and the size, shape, and openings of the cavities of the mouth and nose determine the quality of the sound, i.e. the vowel sound produced. Resonance as applied to this subject means that property of a mass of air by virtue of which it can pick up and intensify the vibrations which fall upon it when those vibrations are of a frequency bearing the proper relation to the size, shape, and opening of the air mass. The vocal cords produce a complex sound composed of a fundamental and a more or less complicated series of over tones; this sound passing out through the cavities of the mouth and nose has certain tones reinforced by virtue of the resonance of the cavities, while other components are practically smothered out from finding no means of reinforcement.

Cases are on record where the whole larynx has been removed and a silver one substituted, so arranged that a simple reed could be inserted, and the patient could articulate just as well as before, with the sole difference that he spoke always on the same fundamental pitch. The system of phonetic writing devised by Alexander Melville Bell, by means of which an expert can represent perfectly any sound, articulate or inarticulate, by simply using a set of symbols that tells the speaker how to place the parts of the mouth, and how to use the breath and voice, is a practical proof that articulation proper is done above the larynx. Evidence in this case is also furnished by the methods of teaching deaf mutes to speak and to some extent by their ability to tell the meaning from the motions of the lips. Individual or race peculiarities of pronunciation may, of course, be due to peculiarities in the dimensions and character of the vocal cords and larynx, as well as to the cavities of the mouth and nose,

etc., but these elements are persistent and affect the voice accordingly.

The third and last element that must be considered under the physics of phonetics is the sound receiving apparatus of the human being. The ear (q.v.) consists of three essentially different parts: the interior ear, where are situated the nerves which perform the actual hearing; the intermediate ear, consisting of a series of little bones which transmit the vibrations of the ear drum to the nerves within; and finally the drum and external ear. The drum takes up the vibrations which fall upon it, and transmits them to the nerves. All of these parts have little or no effect upon the quality of the sound perceived, provided the ear is well and normal. The external ear, however, acting as a collector of the air vibrations and concentrating them upon the drum, does to some extent act as a resonator and distort the quality of the sound produced. This is practically constant for an individual and is not noticed, but it may vary considerably in different individuals, and hence the same sound complex may seem really different to two individuals by the time it reaches the real hearing mechanism.

PHONETIC SPELLING. Spelling according to sound. See **ORTHOGRAPHY**; **SHORTHAND**; **SPELLING REFORM**.

PHONETIC WRITING. Writing according to sound. In the case of languages which have not previously been reduced to writing and thus acquired a stereotyped orthography, phonetic writing is necessarily regularly employed. In

this way many Polynesian, African, and American Indian dialects have received a written form. In languages which already possess an established orthography, phonetic writing is employed either in shorthand or in so-called spelling reform. In the former case the phonographic shorthand signs are afterwards transliterated into the conventional orthography. In the latter instance the sound as heard by the writer is preserved at the expense of the etymology and very frequently of consistency, the same word often being variously written in phonetic spelling by different writers, and with a more or less cumbrous system of arbitrary diacritical letters. In indicating the exact pronunciation of words whose orthography does not represent the sound, some exact system of phonetic writing is usually employed. See **ORTHOGRAPHY**; **SHORTHAND**; **SPELLING REFORM**.

PHONOGRAPH (from Gk. *φωνή*, *phōnē*, sound, voice + *γράφειν*, *graphōin*, to write). The first mechanical device for the registering and reproduction of speech or other sound was the invention of Leon Scott, known as the phonautograph and constructed in 1855. It consisted simply of an ellipsoidal barrel. In this apparatus the sound receiver was open at one end and closed at the other. From the closed end projected a

EDISON PHONOGRAPH.

small tube, across which was stretched a flexible membrane, to the centre of which by means of sealing wax was affixed a bristle, which acted as a stylus, and vibrated with the membrane. In front of the membrane was placed a horizontal cylinder, which was wrapped with a sheet of paper, covered with a thin layer of lampblack, against which the bristle rested lightly. Any sound vibrations entering the ellipsoid were transmitted by the membrane to the stylus, which, when the cylinder was made to revolve, and to advance slowly, described on the lampblack surface a zig-zag line which was thus practically a phonographic record of whatever vibrations had been produced.

The invention of Leon Scott embodies the essential principles on which recording and reproducing instruments of the present day are based. If now we substitute a receiving funnel for the clipsoid, a more rigid or metal stylus for the bristle, and a tin-foil covered cylinder for the lampblack one, we have the phonograph of Thomas A. Edison, as it was originally constructed in 1877; with this essential difference, however, that the sound vibrations were now indented instead of being traced. By reversing the machine—that is, causing a blunt stylus to travel over the indentations made, the original sound was reproduced. Great expectations were entertained of this invention at the time; but it

the wax, the cutting stylus advancing horizontally as the cylinder revolves. In reproducing, another diaphragm, which differs from the first in that it has a different tool and is made of sheets of mica, is employed. The cutting or recording stylus consists of a sapphire with a cup-shaped front which is ground to a fine edge. The reproducing stylus, on the other hand, has a ball-shaped point. This stylus follows the track cut out by the recording stylus. Its motion causes the diaphragm to vibrate, and thus to reproduce the original sound. The machine gets its power from a small electric motor or spring. The sound thus reproduced is not at all equal in volume to the original, but may be strengthened by means of a funnel attached to a reproducer, and by adjusting the speed of the machine sounds may be given out with sufficient loudness to be heard by all in a room. In using a cylinder that already contains a phonographic record, a sharp knife precedes the cutting stylus, thus removing the previous record. A record once made can be reproduced several thousand times without perceptible impairment of its quality, and a record made on one machine can be reproduced on another, thus admitting of the cylinder's being used for mailing, as in ordinary correspondence. There is no limit to the speed with which sounds can be recorded, nor to the number and variety of sounds. The difficulty of concentrating the sounds upon the diaphragm is surmounted in factories where musical and other records are constructed by grouping together the persons or instruments whose sound is recorded. By increasing the speed of the cylinder the pitch is raised, and by lessening it the pitch is lowered. See GRAMOPHONE.

SECTION OF REPRODUCING APPARATUS OF EDISON PHONOGRAPH.

was found that after a few repetitions the record became effaced from the tin foil and the invention proved to be scarcely more than an interesting toy.

During the year 1888 Mr. Edison placed upon the market a phonograph which was a far more elaborate machine as well as more practical than any of its predecessors. The tin-foil gave place to a wax cylinder, which, as shown in the illustration, is slipped over and held on a mandrel. The recording and reproducing devices differ slightly and are shown in the accompanying figures. In operating, the wax cylinder is made to revolve. In talking into the funnel, the malle-

SECTION OF RECORDING APPARATUS OF EDISON PHONOGRAPH.

able glass diaphragm, with a cutting stylus on its under surface, is made to vibrate, and a register of the sound is thus cut vertically into

PHONOGRAPHY. See SHORTHAND.

PHONOLITE (from Gk. φωνή, *phōnē*, sound, voice + λίθος, *lithos*, stone). An igneous rock of porphyritic texture which has a chemical composition essentially equivalent to nephelene syenite (q.v.), and generally contains porphyritic crystals of feldspar (sanadine) and nephelene. Most phonolites have been poured out at the surface of the earth as lavas; as, for example, in the Auvergne of Central France, and in the Cape Verde Islands. Many phonolites possess a platy parting or separation by cracks into a series of parallel plates, so that they give out a peculiar sound when struck with a hammer. On this account they were formerly known as clinkstones. More subject to alteration from atmospheric agencies than most other rocks, they soon lose their fresh appearance, and frequently show the development of crystals of the zeolite minerals.

PHORADEN'DRON. An American plant. See MISTLETOE.

PHOR'BAS (Lat., from Gk. Φόρβας). (1) A son of Lapithes and Orsinome, who freed Rhodes from snakes and was honored by the inhabitants as a hero. He was called *ophiuchus* (the snake-holder) and given a place among the stars. In another legend, Alector, King of Elis, secured his assistance against Pelops, and gave him his daughter, sharing the kingdom with him. (2) A companion of Aeneas. The god of sleep assumed his form in order to deceive Palinurus.

PHOR'CUS, PHORCYS, or PHORCYN. In Greek mythology, an aged divinity of the sea. Hesiod and others make him the son of Pontus and Gaea, and brother of Nereus and Ceto. By

the latter he became the father of the Graces and Gorgons, who are hence called Phoricides or Phorceydes. He was also the father of the nymph Thoosa, who became the mother of Polyphemus, the Hesperides, and the Sirens.

PHORMIO. A lively and interesting comedy by Terence, produced in B.C. 161. It takes its name from the parasite in the play, which was modeled on the *Ἐπιδικαζόμενος* of Apollodorus. From this comedy Molière drew the plot of his *Fourberies de Scapin*.

PHORONIS (Neo-Lat., from Gk. *Φορωνίς*, relating to Phoroneus, from *Φορωνεύς*, *Phorōneus*, Phoroneus, an ancient Greek King of Argos). A marine worm-like animal recently decided to be in a class by itself (Phoronidea). It lives socially, each worm inclosed in a membranaceous or leathery tube. The body is long, slender, not segmented, and around the mouth is a crown of long delicate ciliated tentacles borne on a horseshoe-shaped lophophore. It is hermaphroditic, developing from eggs, and never asexually from buds. The larva is very remarkable; it is a modified trochosphere, and is called an 'actinotrocha.' It may be recognized by the large hood-like lobe overhanging the mouth, while there is a post-oral circle of large ciliated finger-like tentacles; it rapidly metamorphoses into the polyzoön-like adult. It occurs on the coasts of Northern New England and in Europe, while another species inhabits the Australian seas. Consult Harmer, *Cambridge Natural History*, vol. ii. (London, 1899).

PHORORHACHOS, *fō'rō-rā'kōs* (Neo-Lat., from Gk. *φορά*, *phora*, motion, from *φέρειν*, *pherein*, to bear + *ῥαχός*, *rhacos*, brier). A gigantic extinct running bird of prey, skeletons of which are found in the Miocene deposits of Patagonia. It was about 8 feet in height and its skull was larger than that of a horse and armed with a strong hooked beak like that of an eagle. The wings were small and useless, and the legs long and strong and provided with powerful talons. It appears to have been a swiftly running bird, like the ostrich, though actually related to the herons. Consult Lucas, *Animals of the Past* (New York, 1901).

PHOSGENE GAS (from Gk. *φῶς*, *phōs*, light + *γενής*, *-genēs*, producing, from *γίγνεσθαι*, *gignesthai*, to become), CARBONYL CHLORIDE, or OXYCHLORIDE OF CARBON, COCl_2 . A colorless suffocating gas which is formed by exposing equal volumes of carbonic oxide and chlorine to the action of sunlight. If brought into contact with water, phosgene gas rapidly decomposes into carbonic and hydrochloric acids. It may be readily condensed to a liquid, boiling at 8° C. It is largely used in chemical laboratories, as it readily reacts with various substances, so that many organic syntheses can be carried out with the aid of it. It is also employed in the manufacture of certain coal-tar dyestuffs. Phosgene was first prepared by J. Davy in 1811, its name indicating that it was formed under the influence of light.

PHOSPHATES (from *phosphorus*) (in physiology). The following phosphates play an active part in the chemistry of the animal body.

Phosphate of soda occurs in three forms, NaPO_3 , Na_2HPO_4 , and in NaH_2PO_4 , called respectively the basic, neutral, and acid salts. These are all

soluble in water. By exposing the second of these salts to a red heat *pyrophosphate* of soda, $\text{Na}_2\text{P}_2\text{O}_7$, is formed, and by similarly treating the third, *metaphosphate*, NaPO_3 , results. Phosphate of soda in one or the other of the above forms is a constituent of all the fluids and soft tissues of the body, and is especially abundant in the urine and bile. Pyrophosphate and metaphosphate of soda are found in the ashes of animal tissues after incineration, but they result merely from the action of heat on the neutral and acid salts. The salts of sodium are always associated with the corresponding salts of potassium, and what is said of the derivation, elimination, and physiological importance of the one is equally applicable to the other. The alkaline phosphates obviously are derived from the food, being either ingested as such or converted within the organism from other alkaline salts. Elimination is effected chiefly through the kidneys and intestinal canal. In the carnivorous animals, whose blood is much richer in phosphates than that of herbivora (the ash of the blood of the dog, for example, contains from 12 to 14 per cent. of phosphoric acid, while that of the ox or sheep does not contain more than from 4 to 6), these salts are carried off by the urine; but in consequence of the formation of free acids as products of the disintegration of the tissues, a portion of the base is abstracted from the originally alkaline phosphates, and a corresponding portion of phosphoric acid is liberated. The originally alkaline salt is thus rendered neutral or even acid; and the occurrence of the acid phosphate of soda, NaH_2PO_4 , in the urine is thus explained. In the herbivorous animals, on the other hand, the urine contains no phosphates, the whole of the phosphoric acid taken in their food being eliminated by the intestinal canal in the form of the insoluble phosphates of lime and magnesia. Although the general distribution of the phosphates of the alkalies in the nutrient fluids (there is 40 per cent. of them in the ash of the blood-cells; 28.4 per cent. of phosphoric acid and 23.5 of potash in the ash of cow's milk; and about 70 per cent. of phosphoric acid in the ash of the yolk of egg) is in itself an indication of their importance, the exact nature of their functions is not completely understood. Liebig has specially drawn attention to the peculiar grouping of the acid and alkaline fluids of the animal body. The permanence of this grouping is chiefly maintained, especially in herbivorous animals, by the conversion within the body of alkaline and neutral phosphates into acid phosphates by the means already described. Moreover, all tissue-forming substances (the protein bodies) are so closely connected with phosphates that they remain associated during the solution and subsequent re-precipitation of these substances; and the ash of developed tissues (such as muscle, lung, liver, etc.) always affords evidence that acid phosphates existed in the recent tissue; and, further, no exudation from the blood-vessels can undergo transformation into cells and fibres, or, in other words, become organized, unless phosphates are present. Another proof of the share taken by the phosphates in the formation and functions of tissue is the fact that, although herbivorous animals take up a very small quantity of phosphates in their food, and although their blood is very poor in these salts, their tissues contain as large a proportion of phosphates as the corresponding parts of car-

nivora. Lastly, the fact that one equivalent of the alkaline phosphate of soda, Na_2HPO_4 , possesses the property of absorbing as much carbonic acid as two equivalents of carbonate of soda, leads to the belief that the power of attracting carbonic acid, which the serum of the blood possesses, is due as much to the phosphate as to the carbonate of soda, and that, consequently, phosphate of soda plays an important part in the respiratory process.

Phosphate of lime occurs in the organism in three forms, viz.: as the normal calcium phosphate, $\text{Ca}_3(\text{PO}_4)_2$, the monocalcic calcium phosphate, $\text{Ca}(\text{H}_2\text{PO}_4)_2$, also called acid phosphate, and the dicalcic phosphate, $\text{Ca}_2(\text{HPO}_4)_2$. The normal phosphate occurs in all the solids and fluids of the body, but is most abundant in the bones, in which it amounts to about 57 per cent.; and in the enamel of the teeth, in which it ranges from 80 to 90 per cent. It may at first sight appear inexplicable how a salt so perfectly insoluble in water as normal phosphate of lime can be held in solution in the animal fluids. In some fluids, as the blood, it is probably, in part, at least, combined with albumen, with which it forms a soluble compound; while in other fluids, as the urine, it is held in solution by a free acid or by certain salts (as, for example, chloride of sodium), whose watery solutions are more or less able to dissolve it. When too small a quantity of this salt is taken with the food, the bones lose more or less of their hardness and firmness, and fractures do not readily unite. Phosphate of lime, like the phosphates of the alkalis, is indispensable to cell-formation; and in the mantle of the mollusks (where new cells for the formation of shell abound) this salt is far more abundant than in any other part of the body. Although by far the greater quantity of the phosphate of lime found in the body has doubtless preëxisted in the food, yet it is unquestionable that a part of it is formed within the organism by the action of carbonate of lime on the phosphoric acid that is formed during the disintegration of the phosphorus-containing tissues, such as the brain. In man and carnivorous animals, a certain portion of the phosphate of lime is eliminated by the kidneys, and the rest is carried off in the excrements; while in herbivorous animals the whole is carried off in the excrements. The acid phosphate of lime is occasionally found in the urine of man and carnivorous animals, but is of no practical importance. For the amount of earthy phosphates daily eliminated by the kidneys, see URINE.

Normal phosphate of magnesia, $\text{Mg}_3(\text{PO}_4)_2$, is analogous, both in its chemical and physiological relations, to the corresponding salt of lime, with which it is always associated. The abundance of this salt in cereals and vegetables explains its presence in the system. A far less amount of this salt than of the corresponding lime-salt seems to be required by the organism, as is shown by the relative quantities in which they occur in bone (57 of the former to 1.3 of the latter), and as is further indicated by the fact that, relatively, far more of this than of the lime-salt escapes intestinal absorption, and appears in the excrements.

The only phosphates remaining to be noticed are the *phosphate of ammonia and magnesia*, or, triple phosphate, $\text{MgNH}_4\text{PO}_4 + 6\text{H}_2\text{O}$, which occurs in beautiful prismatic crystals in alkaline

urine and urine that is beginning to putrefy, and the *phosphate of soda and ammonia*, which is occasionally found as a crystalline sediment in putrid urine.

PHOSPHATIC DIATHESIS, or PHOSPHATURIA. The excretion in excessive amounts of the earthy salts of phosphoric acid in the urine. Phosphoric acid is excreted in combination with the alkaline bases, sodium and potassium, and the earthy bases, calcium and magnesium. The alkaline phosphates form about two-thirds of the whole, and are always held in solution; the earthy phosphates form about one-third and are spontaneously precipitated under certain circumstances as phosphatic deposits and calculi. One of the causes of such deposition is an alkaline condition of the urine. The urine in health may be temporarily alkaline from eating much fruit or vegetables containing citrates, tartrates, or malates of potassium and sodium. These are converted into carbonates in the intestines and absorbed as such into the blood, and diminish the acidity of the urine or render it alkaline. The urine is sometimes turbid from a white deposit of the amorphous calcium phosphate ($\text{Ca}_3\text{P}_2\text{O}_8$). This may be mixed with a crystalline phosphate ($\text{CaHPO}_4 + 2\text{H}_2\text{O}$), the so-called stellar phosphate, or a phosphate of magnesia ($\text{Mg}_3\text{P}_2\text{O}_8$). A more common condition, however, is that observed when a feebly acid or neutral urine is heated and a thick white deposit or turbidity occurs. In urine which has undergone ammoniacal fermentation there occurs a precipitate of the ammonio-magnesium or triple phosphate ($\text{MgNH}_4\text{PO}_4 + 6\text{H}_2\text{O}$), in the form of minute triangular prisms.

It has been thought that there is a relation between the activity of the nervous system and the excretion of phosphoric acid. An increased amount is seen in the urine after excessive mental work or worry. This phenomenon is also observed in many diseases characterized by wasting and debility, such as phthisis, leucocythæmia, acute yellow atrophy of the liver, and severe anæmias. The old term 'phosphatic diathesis,' signifying a constitutional tendency or habit of body that produced or promoted a deposition of the phosphates from the urine, is no longer recognized.

PHOSPHATIC FERTILIZERS. See MANURES AND MANURING.

PHOSPHINE. See PHOSPHORUS.

PHOSPHOR-BRONZE. An alloy consisting of copper, zinc, and tin in various proportions, with a small quantity of phosphorus which has been introduced in the form of phosphor-tin. The addition of phosphorus has the effect of eliminating the oxides, and, by causing the tin to assume a crystalline structure, increases the homogeneity of the alloy, and thereby its elasticity and absolute resistance. In consequence, phosphor-bronze has met with considerable demand where special strength or power of resisting wear is required, as in the case of bearings for quick-running machinery.

PHOSPHORESCENCE. It has been observed that many bodies continue to emit light in a darkened room after having been exposed to sunlight or some other strong source of light. This phenomenon is called phosphorescence. Although the name is evidently derived from 'phosphorus,'

it should be noted that the cause of the luminosity of phosphorus is a slow oxidation, and is not due to its having been previously exposed to light. Phosphorescence itself is a special case of fluorescence (q.v.), and cases where there are permanent chemical changes are excluded. Those substances which phosphoresce most brilliantly are the sulphides of barium, calcium, and other alkaline earths, diamonds, sugar, etc. It has been found that the phosphorescent light is often brilliantly colored, and also that the color of the light to which the body is exposed in order to excite phosphorescence has a very important influence upon the intensity of the phosphorescent light itself. It is observed that the same law connecting the exciting light and the phosphorescent light holds true as was noted in the case of fluorescence, namely, that the phosphorescent light is of a longer wave-length than the exciting light. A distinction has been drawn between phosphorescence and fluorescence from the fact that only fluids exhibit fluorescence, while only solid bodies exhibit phosphorescence. Nearly all bodies which show fluorescence will show phosphorescence when in the solid state, as, for instance, if when liquid they are dissolved in gelatin and then dried. One of the earliest and most important investigations of phosphorescence was made by E. Becquerel, who made a special study of the interval of time phosphorescence would continue after the phosphorescing body was removed from the light. He invented an instrument known as the phosphoscope, which enabled him to measure with the greatest exactness the small intervals of time involved in the phenomena. He observed that many bodies in which by ordinary means of observation there was no trace of phosphorescence can be shown to phosphoresce for minute fractions of a second. For instance, after exposure to sunlight, calcite shines with orange-colored light; aragonite gives a greenish light, as does lead glass also; uranium glass shines with a greenish light which lasts for about one-thirtieth of a second, although it has its maximum intensity at about one three-hundredth of a second after the sunlight has been withdrawn. Sapphires and rubies give a brilliant pure red light, as do almost all the minerals which contain aluminum.

One most interesting feature of phosphorescence is that if a body is phosphorescing, as for instance a piece of paper covered with Balmain's paint, the application of heat at any one point will destroy the phosphorescence there. This evidently furnishes a method for the study of those portions of the spectra which lie in the infra-red region; i.e. those wave-lengths which are too long to affect our sense of sight. For if a strip of paper covered with Balmain's paint is exposed to sunlight for a short time and then taken into a darkened room and so placed that the infra-red spectrum coming from any source falls upon the paper, those places where there is radiation will be made manifest by the disappearance of phosphorescence owing to the heating effect of the rays of the spectrum. This procedure has been improved by Draper and Lommel, and now forms one of the best methods used in spectrum analysis. See LIGHT; FLUORESCENCE.

PHOSPHORESCENCE OF THE SEA. See LUMINOSITY OF ANIMALS.

PHOSPHORIC ACID, H_3PO_4 . An acid compound of phosphorus, hydrogen, and oxygen, first

obtained by Scheele in 1777. It may be prepared by cautiously heating yellow phosphorus with dilute nitric acid for several hours and driving off the excess of nitric acid by heat. Pure phosphoric acid is a colorless crystalline substance melting at about $41^\circ C$. It is a tri-basic acid, the three hydrogen atoms in its molecule being replaced gradually and the result being three series of salts, like NaH_2PO_4 , Na_2HPO_4 , and Na_3PO_4 . The 'neutral' salts of the alkali metals have a strongly alkaline reaction. When heated above $300^\circ C$. phosphoric acid is converted into pyrophosphoric acid, $H_4P_2O_7$, which was first prepared by Gay-Lussac in 1829. Several of the salts of phosphoric acid are used in medicine. The most important phosphates are described under the names of the metals. See also PHOSPHORUS.

PHOSPHORITE. The massive, concretionary, and mammillary form of apatite, especially the variety found in Estremadura, Spain. The name was first used by Kirwan in describing the phosphates found in Spain, which occur in veins and in pockets in the Silurian schists.

PHOSPHOROSCOPE (from Lat. *phosphorus*, Lucifer, phosphorus + Gk. *σκοπεῖν*, *skopein*, to behold). An apparatus invented by Becquerel for measuring the duration of phosphorescence in different bodies. See PHOSPHORESCENCE.

PHOSPHOROUS ACID, H_3PO_3 . A di-basic acid formed by the action of water on trichloride of phosphorus. It is a crystalline substance melting at $70^\circ C$. Its salts are termed phosphites.

PHOSPHORUS. One of the non-metallic chemical elements. It was discovered by Brand, a Hamburg alchemist, in 1669, while experimenting with urine with a view to preparing a liquid for the transformation of silver into gold. Kunekel, on learning of the discovery, without, however, knowing the method, invented a process of his own for the extraction of phosphorus from urine, and in 1678 published a work entitled *De Phosphoro Mirabili*. The existence of phosphorus in bones was discovered either by Gahn (about 1769) or by Scheele (1771), and subsequently phosphorus became a well-known and cheap substance, variously called Brand's phosphorus, Kunekel's phosphorus, Kraft's phosphorus, Boyle's phosphorus, and English phosphorus, while the name phosphorus, unqualified, was applied to phosphorescent substances in general until the antiphlogistic nomenclature introduced the present usage. The elementary nature of phosphorus was first recognized by Lavoisier. See CHEMISTRY.

Phosphorus does not occur free in nature, but is found abundantly in the form of phosphates. The minerals of the apatite group (combinations of calcium phosphate with calcium chloro-fluoride), struvite, vivianite, wavelite, and many other minerals contain considerable amounts of chemically combined phosphorus. But the principal source of phosphorus is still the substance of bones, which consists chiefly of the neutral phosphate of calcium. Calcium phosphate is also the chief constituent of coprolites and guanos, and calcium and magnesium phosphates are found in the ashes of plants. Ammonium-magnesium phosphate is the chief constituent of urinary sediments, while in combination with carbon, hydrogen, oxygen, and nitrogen, phosphorus is found in

the yolk of eggs, in the blood and other animal fluids, and in the substance of the brain and nerves.

To obtain phosphorus, bones are burned to destroy their organic matter and are treated with sulphuric acid, which converts the neutral phosphate $\text{Ca}_3(\text{PO}_4)_2$ into the soluble acid phosphate, $\text{CaH}_2(\text{PO}_4)_2$. The solution of the latter is evaporated to dryness, charcoal is added to the residue, and the mixture is strongly heated, when two processes take place in immediate succession, the first consisting in the transformation of the acid calcium phosphate into calcium metaphosphate, $\text{Ca}(\text{PO}_3)_2$, the second in the partial decomposition of the metaphosphate by the charcoal, resulting in the formation of free phosphorus, some neutral calcium phosphate, and carbonic oxide gas. The phosphorus vapors are condensed under water in suitable vessels of clay. The crude product thus obtained may be somewhat purified by melting under water and pressing through porous plates. Arsenic, an impurity usually introduced with the sulphuric acid employed in the manufacture of phosphorus, may be removed by means of nitric acid. When pure, the phosphorus is melted and cast in the form of sticks by sucking it into glass tubes and allowing to solidify.

The chemical symbol of phosphorus is P; its atomic weight is 31. The properties of free phosphorus are not always the same, the element being capable of existing in several different allotropic forms. (See ALLOTROPY.) The vapor of phosphorus has invariably the same density, leading to the molecular formula P_4 . (See MOLECULES—MOLECULAR WEIGHTS.) Experiment leads to the view that when dissolved in benzene phosphorus has a similar constitution. But the remarkable differences between the liquid and the several solid modifications of the element are by no means understood. Common or yellow phosphorus, which is ordinarily obtained by the manufacturer, is a transparent waxy substance that may be prepared in the form of crystals of the regular system by sublimation or by crystallization from solutions in carbon disulphide, in which the other varieties of phosphorus are insoluble. Its melting-point is 44.5°C . and its specific gravity at 0°C . is 1.837. It phosphoresces in the dark, and although it has been shown to exhibit this phenomenon when kept in gases incapable of reacting with it, it is quite certain that in all such cases the phosphorescence is caused by the presence of traces of oxygen, which oxidizes yellow phosphorus very readily. As a matter of fact, when kept in a vacuum or in gases which have been thoroughly freed from oxygen, phosphorus gives off no light. In the air, at ordinary temperatures, yellow phosphorus undergoes slow oxidation (see OZONE), and may readily take fire even if carelessly rubbed. It may be caused to burn under water by gently warming the latter and passing a current of oxygen into it. Besides, yellow phosphorus is extremely poisonous. It must therefore be handled with great care. The use of phosphorus for matches is well known. (See MATCHES.) *Red phosphorus* was discovered by Schrötter, of Vienna, in 1845. It is gradually formed by the action of light, especially violet rays, on common phosphorus, but may be conveniently prepared by simply heating the latter to about 250°C . (450°F .), in an atmosphere of carbonic acid, nitrogen, or some other inert gas. If heated to about 300°

C ., red phosphorus is reconverted into the common yellow modification. The specific gravity of red phosphorus is about 2.14, and it does not melt. It does not phosphoresce in the dark, is not poisonous, and is in every way perfectly harmless. (See MATCHES.) *Crystalline* ('metallic') phosphorus is formed during the solidification of molten amorphous phosphorus. It may be obtained in the form of long red tabular crystals having a distinct metallic lustre. Its specific gravity is 2.34. *Black phosphorus* is formed when melted yellow phosphorus is rapidly cooled. Two other allotropic varieties of phosphorus have been described, but deserve no mention here.

COMPOUNDS OF PHOSPHORUS. Phosphorus forms at least three different compounds with hydrogen: viz. a solid hydrogen phosphate, P_4H_2 ; a liquid phosphide, P_2H_4 ; and a gaseous phosphide, PH_3 , called phosphine. The last-named compound, analogous to ammonia (NH_3), is usually prepared by heating phosphorus with a strong solution of caustic potash. When thus prepared, however, it contains some vapor of the liquid phosphide, P_2H_4 , and as the latter takes fire spontaneously in the air, the impure phosphine, too, is inflammable. But under the influence of light, or by the action of strong hydrochloric or sulphuric acid, and certain other substances, the vapor of the liquid phosphide is decomposed; and if pure phosphine is prepared, say, by passing the impure gas through concentrated hydrochloric acid, it is found not to take fire in the air. The odor of phosphine resembles that of garlic and of rotten fish. The oxides of phosphorus include phosphorus trioxide, P_2O_3 , and phosphorus pentoxide, P_2O_5 . The latter, usually termed 'phosphoric' anhydride, is formed when common phosphorus burns in the air. It forms a white, exceedingly hygroscopic powder, taking up water with great energy to form phosphoric acid. With the halogens phosphorus forms a trichloride, PCl_3 ; a pentachloride, PCl_5 ; a tribromide, PBr_3 ; a pentabromide, PBr_5 ; and a triiodide, PI_3 . All these compounds are formed by the direct union of the elements. A tri-fluoride, PF_3 , and a pentafluoride, PF_5 , are also known.

Phosphorus is a constituent of many tissues, especially the nerve-centres, and its physiological action is that of a tonic. It is chiefly used in medicine in nerve exhaustion, myelitis, neuralgia, osteomalacia, and rickets. It has been used with success in lupus, acne, and psoriasis. It may be given in pill or in solution, the latter being preferable. It may be exhibited dissolved in oil or in chloroform. Phosphide of zinc has been used as a substitute for phosphorus. See ANTIDOTES.

PHOSPHORUS (Lat., from Gk. φωσφόρος, light-bringer). A name of the planet Venus as the morning star, also called Lucifer. As an evening star it is called Hesperus and Vesper.

PHOTIUS, fō'zhī-ūs (Lat., from Gk. Φώτιος) (c.820-c.891). Patriarch of Constantinople, one of the greatest theologians and scholars of the Greek Church. He was a member of a patrician family of Constantinople, and during the first period of his life filled various important public offices. In 857 Bardas, minister of the young Emperor, Michael III., undertook to remove the Patriarch Ignatius (see IGNATIUS, SAINT) from his position, and Photius, after being hurried through all the clerical offices in a few days, was put in his place. Pope Nicholas I. (q.v.) espoused the

cause of Ignatius and excommunicated Photius in 863. The latter maintained his position, supported by the Court, and in 867 assembled a council at Constantinople which excommunicated the Pope and his partisans, and withdrew from communion with the See of Rome. (See GREEK CHURCH.) The same year Basil I. succeeded Michael as Emperor, Photius was deposed and Ignatius reinstated. Ten years later, after the death of Ignatius, Photius was restored, and the Pope, John VIII., was induced to acquiesce; but in 881 he also excommunicated the Patriarch, whose relations with Rome continued unfriendly the rest of his life. In 886 the Emperor Leo banished Photius to an Armenian cloister, and he died there about five years later. Photius is revered by the Greek Church, while the Western Church accuses him of craft, violence, and perjury. His theological works include the *Amphilochia*, which not only discusses doctrinal and exegetical questions, but treats also of philosophy, science, medicine, grammar, and history; commentaries on the Gospels and Epistles; and a treatise in favor of the Greek doctrine of the procession of the Holy Spirit. The *Nomocanon* ascribed to Photius is of doubtful authorship. His chief literary and scholarly work is the *Myriobiblion* or *Bibliotheca*, a summary review of nearly 300 works which he had read, most of which are now lost. He also wrote a *Lexicon*, for use in reading the classic authors and the Scriptures. A number of Photius's letters are preserved, as well as sermons of much merit. His works are in Migne, *Patrologia Græca*, ci.-ev. Consult: Hergenröther, *Photius, Patriarch von Constantinopel* (3 vols., Regensburg, 1867-69); id., *Monumenta Græca ad Photium Spectantia* (ib., 1869).

PHOTO-CHEMISTRY. The branch of general chemistry that deals with chemical changes immediately producing or caused by light. In interpreting this definition it must be borne in mind that the combustion of illuminants cannot properly be classed as a form of photo-chemical changes, for the reason that combustion transforms the chemical energy of the illuminant, primarily not into light, but into heat, the latter then giving rise to the production of light. The chemical changes immediately producing light include those undoubtedly taking place at ordinary temperatures in the fireflies and other luminescent organisms, as well as in the eye. All such changes are as yet very imperfectly understood, and photo-chemical research has been confined almost exclusively to the opposite phenomenon, i.e. to chemical changes caused by light.

ACTINOMETRY. That light is capable of causing chemical transformations was not unknown in the eighteenth century. That silver chloride turns dark under the action of light was known to Schultze as far back as 1727. In the latter part of the century it was recognized that sunlight enables plants to decompose carbonic acid gas and set free its oxygen, and about 1840 Liebig grasped the full importance of this process in the economy of nature. But all photo-chemical knowledge remained qualitative until John W. Draper, of New York University, about 1842, introduced the quantitative measurement of the chemical action of light, by constructing the first 'actinometer.' Gay-Lussac and Thénard had

observed in 1809 that a mixture of equal volumes of chlorine and hydrogen, which may be preserved indefinitely in the dark, reacts with explosive rapidity if exposed to intense light, and slowly if the light is weak. The product of the reaction is hydrochloric acid gas, which is freely soluble in water, while hydrogen and chlorine are soluble only sparingly. To measure the effect of light in causing the reaction, Draper introduced a mixture of precisely equal volumes of hydrogen and chlorine into a glass bulb (a) half

DRAPER'S ACTINOMETER.

filled with water and joined to a glass tube (b) likewise filled with the gaseous mixture, provided with a scale, and in its turn joined to a wide vessel (c) filled with water. He then exposed the upper part of a to light, whereupon part of the hydrogen and chlorine combined into hydrochloric acid, the latter was absorbed by the water, and the consequent diminution of the gaseous volume was shown by the length of the column of water entering from c into b. Draper's actinometer was improved in 1862 by Bunsen and Roscoe. But even the improved form of the apparatus did not permit of sufficiently rapid experimentation, and consequently the method was soon abandoned. Instead, Bunsen and Roscoe employed an actinometer which measured the chemical intensity of light by the time required to darken a photographic film to a certain standard degree.

In 1879 Eder devised a new method of actinometric measurement. If a mixture of mercuric chloride (corrosive sublimate) and ammonium oxalate in aqueous solution is exposed to the action of light (especially the ultra-violet rays), a chemical change takes place resulting in the precipitation of mercurous chloride (calomel), the quantity of which measures the chemical intensity of the light. Account must of course be taken of the fact that the amount of calomel precipitated not only depends on the intensity of the light, but is also influenced by the varying concentration of the solution during the experiment.

In 1897 Rigollot constructed an actinometer by immersing into a solution of common salt two copper plates whose surfaces were previously oxidized in the flame of a Bunsen burner, and exposing one of the plates to the light. If the two copper plates of this apparatus are connected by a wire, an electric current is found to flow from the dark plate toward the illuminated one, the intensity of the current being proportional to the intensity of the light, and hence being capable of serving as a measure of the latter. It may be observed that the principle of electrochemical actinometry was discovered as far back as 1839, by Becquerel, who found that a current passed between two silver plates covered with films of chloride of silver and immersed in dilute sulphuric acid if one of the plates was exposed to the light.

GENERAL PRINCIPLES. Passing now to the few known general principles of photo-chemistry, it must be observed first of all that while it was formerly believed that light of certain colors only ('actinic rays') was capable of chemical action, it is now generally admitted that chemical

changes can be produced by light of any wavelength whatever, including the infra-red and the ultra-violet rays. It is further generally admitted that if a substance is at all incapable of absorbing light, it is also incapable of undergoing photo-chemical changes of any kind. It is often possible, however, to increase the capacity of a substance for absorbing light, by mixing it with other substances which absorb light freely.

When light produces a chemical change, it naturally loses more or less of its original intensity, part of its energy being transformed into chemical energy. When, therefore, light passes through a medium in which it causes some chemical change, its intensity is diminished, first through purely optical absorption, and secondly through 'photochemical extinction.' Thus, for example, if light is passed through a given volume of chlorine gas, it is partly converted into heat and its intensity is found to have diminished by a corresponding amount. If now, in a second experiment, light of the same original intensity is passed through a mixture of chlorine and hydrogen, the intensity is found to have diminished by a greater amount than in the first experiment, owing to the photochemical combination of chlorine and hydrogen into hydrochloric acid. The absorption of light by the hydrogen gas present in the second experiment is small and may be left entirely out of account. In either experiment, the diminution of intensity may of course be measured by means of one of the actinometers described above.

In conclusion, it may be pointed out that if a given substance is capable of undergoing a chemical change both under the influence of light and without this agency, the change in the two cases need not necessarily be quite the same. Thus it has been proved that the decomposition of hydriodic acid takes place, under the influence of light, according to the equation.

i.e. molecule after molecule of hydriodic acid is primarily decomposed into single atoms of hydrogen and iodine. On the other hand, if hydriodic acid is decomposed by heat, without the intervention of light, the decomposition takes place according to the equation

i.e. the molecules are decomposed in pairs, each pair yielding a molecule of hydrogen gas and a molecule of iodine.

See PHOTOGRAPHY; PHOTOSYNTHESIS; PHOSPHORESCENCE; ACTIVITY.

PHOTO-ENGRAVING. The art of preparing, by means of the chemical action of light upon certain bodies, an engraved plate or block for printing. There are two forms of this as there are of manual engraving; namely, engraving in intaglio, in which the ink for printing enters the incised lines and remains there while the rest of the plate is cleaned off; and relief engraving, in which the ink is deposited upon the projecting parts of an engraved block or plate.

In either case the paper takes the ink from the surface as in the printing of ordinary manual engravings. Photo-lithography, or the preparation by chemical effects of light of plane surfaces for printing, is treated under LITHOGRAPHY.

INTAGLIO PHOTO-ENGRAVING. This is known by the general name *photogravure*, a French term generally accepted in all languages. Heliogravure is a term which may be taken as the equivalent of photogravure, varying in meaning as does that more general term; but at different times the name heliogravure has been given to special patented or secret processes. Photogravure may have the appearance of pure line work, exactly as in manual line-engraving (q.v.), and it may have the appearance of tint or shade without line, nearly as in the case of mezzotint (q.v.). This form of the art has been carried to such perfection by some workmen, especially in France, that it is to be compared only to the finest and most artistical hand work, having in addition to that artistic charm an accuracy of reproduction which the manual work cannot pretend to. Thus in the large books on painting and monographs of special painters issued during the last twenty years, and especially the more recent ones, such as De Beruete's *Velasquez*, Yriarte's *Mantegna*, Lady Dilke's *French Painters of the Eighteenth Century*, Armstrong's *Gainsborough*, *Turner*, and other volumes, and the splendid catalogues of public and private collections, photogravures alternate with half-tone prints and other prints from photo-engraving plates, but the photogravures are distinguishable at once by the fineness of their texture (pure line in the one case and grain or texture in the other), in which no other process can approach them. In the case of line photogravure the facsimile of a drawing or of a print from an engraved plate may be so perfect as to be so indistinguishable from the original except by the most minute examination of an expert. Thus in the published work of Amand-Durand of Paris, the facsimiles of fine prints from the plates of Dürer, Rembrandt, Claude, Paul Potter, and other celebrated etchers and line engravers caused astonishment and doubt among collectors of prints when those facsimiles first appeared about 1870. Here was an unquestioned original Rembrandt, not a copy, as any student of Rembrandt would know, and yet it was printed upon modern paper. In all these processes, however, hand work has to be called in to complete the plate; and it is a general truth that the most artistic workmen produce the most perfect photogravures. In the case of Amand-Durand there was the peculiar advantage that the director himself was a skilled engraver before he undertook the photo-engraved process.

Gelatin treated with bichromate of potash is made insoluble under the action of light. Instead of gelatin some other form of albumen may be used, or asphaltum, which is found to answer equally well and to be cheaper. In making a photogravure in line a photographic transparency, or positive, of the drawing or print or picture or object which is to be reproduced is placed in contact with a copper plate coated with asphaltum or albumen mixed with a bichromate, and strong light is allowed to pass through the negative to the sensitized surface. Only those parts where the light passes through the negative with-

out interruption will be marked by complete insolubility of the gelatin; elsewhere the surface remains soft and capable of being dissolved away by washing. In this way the surface of the prepared plate affected by light is turned into a relief copy of the original. The plate is then etched by an acid, perchloride of iron, which eats it away exactly as in the case of ordinary etching (see ETCHING). When it is a line plate which is being prepared no other important steps are necessary; but when the plate is to be a tint plate or gradation plate without line and producing prints much like those taken from a mezzotint, it is usual to prepare the surface of the copper plate in the first place, by precipitating upon it a fine powder of resin or of resin and asphaltum in combination. This powdered surface prevents the complete access of the mordant to the metal exactly as in the case of aquatint (q.v.). The granular surface so obtained may be either coarse or indefinitely minute, this depending upon the character of the subject to be reproduced. In this way the reproductions of portraits by the greatest master of refined execution or landscapes of minute detail of most varied character may be reproduced with a perfectness of gradation equal to that of hand work in its highest perfection.

As it has become customary to illustrate costly books by means of large photogravure plates, so it has become usual to employ living artists of celebrity to make original monochrome pictures for such reproduction. These are sometimes produced in the more usual fashion by means of water-color work in bistre, sepia, India ink, or other one-colored pigment, but they are also made on a very large scale by oil painting upon canvas, exactly as in the case of paintings intended for exhibition or sale, except that they are worked in such gray or brownish-gray pigment as the painter and the photographer agree upon as convenient for the one and most easily adapted to the work of the other. Such monochrome paintings are often of considerable importance, and those collectors of works of art who have purchased them at the time of their production have considered them an important part of their possessions. It may be stated, also, that the improvements made in orthochromatic photography have made it possible to obtain very accurately the relative color values of the most difficult subjects, elaborate oil paintings, and the like.

The difficulty with the employment of photogravure in book work is the great cost, not alone in the production of the plates (for it is not uncommon to take two or three months in the perfection of a large plate), but of the printing, which has to be done on a hand press, and slowly, so that every separate impression, of which fifty may be bound up in a folio volume, will have cost a definite sum of money over and above the cost of the plates. It is on this account that modified processes are continually brought forward intended to produce plates from which the printing may be done more rapidly. There is, however, always the difficulty in printing from intaglio-engraving, that in order that the paper shall take the ink from the incised lines perfectly, leaving none behind, so that the design is reproduced in every minute particular by the raised pattern of ink on the paper, only a slow and painstaking process will serve.

A kind of photogravure has been introduced in which a screen is employed to make the grain exactly as in the case of the half-tone process described below. This, of course, if perfected, will tend toward much greater ease in rapid printing.

RELIEF PHOTO-ENGRAVING. This covers all those processes by means of which a surface is prepared like that of a wood engraving, the lines, points, and small surfaces which are to be reproduced upon the paper standing up in low relief from the background which is cut away. The level surfaces of these lines and points must be exactly true and uniform, all in one plane, except where it is deliberately lowered in one place or another in order that the block at that point shall press the paper less firmly and the ink impression show pale in contrast with other and blacker parts.

One of the most difficult of these processes is that called commonly the Gelatin Process, or, to distinguish it from others also depending upon gelatin, the 'swelled gelatin process.' It is an expensive process and one requiring the greatest care to employ it successfully, but its results are not very markedly inferior to that of photogravure which is not in distinct line. In fact, a good print made by this process may be often taken for a photogravure print of somewhat inferior excellence, without clear black and white, with a too uniform texture and a cloudy rendering of details. A sheet of glass is coated with a film of gelatin sensitized with bicromate of potash and exposed under a black and white negative. The film is then soaked in water and swells up where the opaque lines corresponding to the whites of the design protected the film, while the surface of the film corresponding to the black lines of the design do not swell. From the surface so produced a matrix is made, and from this another in a material such as wax, and, again, an electrotype of copper is made and mounted upon a block to give it the requisite stiffness and thickness.

The Woodbury type, the collotype, the artotype, the heliotype, the albertype, and many similar processes are all based upon the properties of certain resinous and glutinous substances, and their changes when submitted to light. Asphaltum, albumen, and gelatin are the three used.

The Half-Tone Process has resulted from the invention of the mechanical art of ruling lines of extreme fineness, of perfect uniformity in width, and at absolutely equal distances from one another. This, which was not practicable until within comparatively recent years, has now been developed so that plates of glass can be ruled in this way with minutely incised lines, two hundred or even three hundred to an inch. When two glass plates, each ruled with lines of this sort, for instance, diagonally across the plate, are brought together in such a way that the two sets of lines cross one another, the result is, as seen by transmitted light, a fine network of square or diamond-shaped mesh. The half-tone process depends upon this 'screen,' as it is called. The photographic negative is made by light passing through this screen, placed at a suitable distance in front of the sensitive plate, and the result is an image broken up into minute dots, easily seen with a magnifying glass. There is no absolutely continuous gradation of tint; but everywhere a

series of very small dots which constantly increase and decrease in darkness or intensity, conditioned upon the relative lights and darks of the subjects to be reproduced, and which are small enough to produce a general effect of uniform gradation. This negative reversed is placed in contact with a carefully prepared copper plate, the zinc is also used that has been coated with a preparation of fish-glue, bichromate of ammonia, albumen, and water. It is then exposed to the light and afterward washed in water, and those parts protected from the light by the dense portions of the negative will be washed out of the half-tones in due proportion. After burning in—that is, heating over a gas stove—the plate is all ready for etching, which is done in the case of a copper plate with perchloride of iron, or with zinc nitric acid.

The half-tone process requires less artistic sense and ability than, for instance, photogravure, but it requires the neatest handling, the most perfect delicacy of treatment, and it is often necessary for a good block that the acid should be applied in several consecutive 'rebitings' before the surface is perfect. In much of the finest work of to-day the highest lights and delicate tone gradations are very skillfully retouched by an experienced wood-engraver. Much of the re-engraving by hand, however, is clumsily done, and adds to the shortcomings of poor plates.

The special utility of the half-tone block is in this, that it can be printed with type. In order that this may be done, the metal plate is backed up by a block of wood of the right thickness, so that the surfaces of the prepared metal shall be exactly even with the front of the types. With reasonably careful work in the preparation of the stereotype plates and the like, a page may be printed of typography with pictures of full light and shade incrustated in it; the whole printed together, and that even on the power press.

The Line-Cut Process gives an exact facsimile of a drawing in solid or dotted black lines. Any drawing which an artist will make with a point, as of a pen, or a brush, and which does not include tints or half-tones, can be reproduced in exact facsimile. The process is similar to those described above. The light passing through the negative hardens the prepared surface, and the unsoftened stuff is washed away. In fact, this may be considered the original process from which the half-tone process has been produced by natural evolution, that is by the development along obvious lines. The line-cut block can be used in connection with type exactly as half-tones at a very much less cost and with greater facility and less care in the manipulation.

COLORED PRINTING FROM PHOTO-ENGRAVED SURFACES. The most important process of this kind is that known as the Three-color Process. This has become a very familiar and widely used process and promises well. The system is based upon the scientific fact that all the colors of the spectrum may be obtained from the three primaries, red, blue, and green. The rays of light are separated by means of what are called photographic filters, which are partly transparent substances which allow particular rays to pass while they stop or restrain others. Thus one of the three filters will allow only blue rays to pass. By this appliance used in connection with

the half-tone process there may be produced a perfect blue picture, and again with the use of other filters a green and a red, or approximately red picture. The printing of all these, one upon another, approximates very closely the complete chromatic result desired, that is to say, a picture in full color. The chief difficulties of the process are in the making of correct negatives, accurate registration in printing, and appropriately colored inks. The result so far may be said to approximate to the reproduction of fine manual painting. One obvious reason for this imperfection of the result is found in the inferior effect of colors superimposed to those which are laid side by side. Every student of painting knows how much more brilliant a gradation can be procured by putting touches of color close together, side by side, than by laying those colors over one another. It is true that much work, especially in oil painting, is done by superimposed color, but this is when the upper coat of pigment is more or less translucent, as when the yellow below shows through the thin glaze of blue to produce a certain quality of green. Commonly the juxtaposition of color is more brilliant than the superimposition of color; and this fact causes an indefinitely great amount of thought and experiment among those who are trying to improve the three-color process.

Another and more complex process of photographic color work has been introduced in the United States within the last four years, and some of the results are surprisingly accurate reproductions of the originals. The greatest successes in the color work have been obtained in the reproduction of colored textiles, notably in imitating the richness of color and texture of Oriental rugs. This is a secret process, and the methods employed are very carefully guarded. It is something more than the ordinary three-color work, and apparently as many as seven colors are employed in some cases. It is as yet costly.

PHOTOEPINASTY (from Gk. *φῶς*, *phōs*, light + *ἐπι*, *epi*, upon + *ναστός*, *nastos*, solid, from *νάσσειν*, *nassein*, to press close). The action of light in accelerating the growth of the upper sides of dorsiventral organs, such as leaves. See GROWTH.

PHOTOGRAPHIC SURVEYING (from Gk. *φῶς*, *phōs*, light + *γράφειν*, *graphēin*, to write). In recent times the art of photography has found its way into surveying, an application due chiefly to the French. Its advantage was at once recognized for military and topographical purposes, but its usefulness for accurate and extensive surveys is still quite limited, owing to the imperfections of the photographic lens. The chief instrument is a view camera provided with cross-wires and an apparatus for leveling. A survey is effected by selecting at least two stations, and measuring the base-lines between them. Then at each station a series of plates are exposed, the camera being turned at each successive exposure sufficiently to obtain for the series a continuous photograph of the area to be surveyed. The method of executing a map and of calculating heights and distances from photographs is best obtained from works on the subject, but a general idea may be gained from the following. Since the images of the cross-wires are photographed on the plate, every point of the field

appears in its proper position in relation to the four quadrants of the plate. Thus in Fig. 1 III'

FIG. 1.

is the image of the horizontal wire, VV' the image of the vertical wire, and P the image of a church spire. The lines a and b can be measured in the photograph, and the focal distance f being known, line d can be computed, and when the distance OA has been determined from the map, the height of the spire above the level of the instrument is given by similar triangles. To plot a survey, the angular distance of any point from the base-line is determined by a photograph taken at each end of the base. In Fig. 2, P represents the plate of the camera at station A; B', C' being the images

FIG. 2.

of station B and the point C; the angle $B'OC'$ can be determined from $B'C'$ and the focal length f . Then any point of the map may be plotted as follows: Lay off the base-line to a desired scale, and draw lines making angles with the base equal to those computed. These will intersect in a point on the map corresponding to the point in the field. Consult Deville, *Photographic Surveying* (Ottawa, 1895). See SURVEYING.

PHOTOGRAPHY. The art of producing the appearance of objects and fixing them by means of light on a previously sensitized surface, and the reproduction of the image thus obtained, by various processes, on glass, paper, and other materials. The first photographic camera was in reality a darkened room to which light was admitted through a single small hole in the window shutter. This was the camera obscura of Giambattista della Porta, an Italian philosopher, invented by him in the last half of the sixteenth century. When the sun shone brightly, a faint inverted image of a landscape could be seen on the whitened surface of the wall within. The camera obscura of the present time differs very little from Porta's invention except that it contains a lens in the apex of the roof, with a reflecting mirror above it, in order to throw the light from all the surrounding landscape down through the lens and thus form a panorama on the surface of a table placed in the middle of the room. J. H. Schultze, a German, who has been called 'The Columbus of Photography,' obtained the first actual photographic copies of writing as early as 1727, by placing the written characters upon a level surface previous-

ly prepared with a mixture of chalk and silver nitrate. The rays of light passing through the translucent paper blackened the silver compound underneath, except where it was protected by the opaque ink forming the letters themselves, and thus a white copy upon a black ground was obtained.

Scheele in 1777 demonstrated that silver chloride became black quickest by the action of the violet rays of the solar spectrum, thus showing that the rays of light were not equally active. A few years later Professor Charles projected the shadow of a head by means of strong sunlight on a sheet of white paper which had been made sensitive by chloride of silver and obtained a white profile on a darkened surface; but he was unable to fix the image upon the sensitive paper. Meanwhile the members of the Lunar Society, including Samuel Parr, James Watt, Josiah Wedgwood, and others, met regularly at the house of Matthew Boulton at Soho and discussed their experiments, some of which were on the action of light, and it has been shown that an artist named Eginton, in the employ of Boulton, made and sold numerous copies of well-known paintings at very low prices. Thomas Wedgwood, to whom is due the honor of being the first to produce pictures by the action of light on a sensitive surface, published his paper giving "an account of the method of copying paintings upon glass, and of making profiles by the agency of light upon nitrate of silver, with observations by H. Davy," in the *Journal of the Royal Institute* for June, 1802. To Davy credit is due for his discovery that silver chloride was more sensitive than the nitrate; but, notwithstanding his continued investigations, Davy was unable to find a means by which the fading out of the pictures could be prevented. Other investigators took up the subject later, among whom may be mentioned Joseph Niepce and Daguerre in France, and William H. F. Talbot in England. The first-named, in 1814, succeeded in producing permanent pictures by a process which he called *heliography*. It consisted in coating with bitumen a piece of plated silver or glass, which was then exposed in a camera obscura during 4 to 6 hours. Those portions of the bitumen which were acted on by the light became insoluble, and by removing the parts unacted upon by certain essential oils in which bitumen was soluble, the shadows of the image were removed, and the lights were represented by the insoluble bitumen that remained on the plate. This process was therefore the forerunner of our modern photo-mechanical methods. In 1824 Daguerre began his experiments, which led to the invention of his celebrated process. He formed a partnership with Niepce in 1829, and ten years later they announced the invention of the daguerreotype process, the principle of which had been discovered by Daguerre in 1832. The process consisted in exposing a metal plate covered with silver iodide for twenty minutes in a photographic camera, after which the plate was transferred to a dark room and exposed to the vapor of mercury, which developed the latent image, the latter being then made permanent by means of a solution of sodium chloride. Sir John Herschel, who devoted considerable attention to this subject, soon after announced the greater suitability of sodium hyposulphite for dissolving the haloid salts of silver and consequently the hyposulphite was adopted as a

fixing agent. Daguerre received a pension of 6000 francs from the French Government on August 10, 1839, in consideration of which the details of his process were given to the world. Information of this invention reached the United States in 1839 through Samuel F. B. Morse, who communicated it to his colleague in New York University, John W. Draper (q.v.), by whom the first sunlight picture of a human face (that of his sister Dorothy Draper) was made in 1840. Meanwhile Talbot, in England, had been pursuing investigations from a different view-point, and on January 31, 1839, he presented before the Royal Society a paper on "Pathogenic Drawings." These he produced by dipping writing paper in a solution of sodium chloride, drying, and then transforming the sodium chloride into silver chloride by passing the paper through a solution of silver nitrate. With this paper, which was extremely sensitive to light, he was able to produce a negative that became black by the action of sunlight except where it was covered by some opaque object, which he desired to reproduce, and in turn from this negative, by another exposure, a number of positive prints could be obtained, which were fixed by potassium bromide. Two years later Talbot patented his 'calotype' process, in which the negative was obtained by coating the surface of the paper with silver iodide, then washing it over with a mixture of silver nitrate with gallic and acetic acids, after which it was exposed in a camera to the object he wished to copy. The invisible picture thus obtained was developed by silver aceto-nitrate and gallic acid, and fixed with potassium bromide. Minor inventions and improvements followed the introduction of Talbot's process, among which the most important was the use of albumen, recommended by Niepee de St. Victor as a film containing haloid salts which he flowed upon the surface of the glass.

The development of the modern rapid processes of photography may be said to have begun with the introduction of the dry collodion process by Scott Archer in 1851. This process consists in coating glass plates with a film of collodion containing soluble iodides or bromides, which form a sensitive silver compound when dipped in a solution of silver nitrate. The soluble collodion is prepared by the action upon cotton of a mixture of nitric and sulphuric acids with a little water, or of a mixture of potassium nitrate with sulphuric acid, the resulting substance being dissolved in a mixture of alcohol and ether. On evaporation, the viscous solution leaves a film of collodion. The exact proportions of the ingredients used must be varied at different seasons of the year, and must be suited to the character of the objects to be photographed, one variety being suitable for landscape views, another for portraiture, etc. The collodion is flowed over the glass plate, which must be perfectly clean, and when partially dry sensitized by dipping into a bath containing silver nitrate in the proportion of from 35 to 50 grains of the salt to an ounce of water. A very small quantity of potassium iodide is added to the bath. The sensitized plate is then exposed in the camera to the object to be taken. The action of the light on the sensitive silver salts changes them in such a way as to produce a latent image on the film, which is then developed by pouring over the plate a solution of ferrous sulphate or pyrogallie acid, to either of which are added some

alcohol and acetic acid, after which the image on the plate is made permanent or fixed by immersion in a solution of sodium hyposulphite, potassium cyanide, or some other liquid capable of dissolving the portion of the silver salts that has not been acted upon by the light. For the protection of the collodion film it is common to coat the negative with a clear and hard varnish.

As the wet process required that the plates be prepared at the time of exposure, that process naturally found its most extensive employment for indoor work, and continual efforts were made to devise portable plates. Finally plates were introduced which were sensitized, washed, dipped in some organic preservative, such as a solution of tannin, and then dried.

In 1871 Maddox introduced the earliest form of the 'gelatin-emulsion process,' which has since been considerably improved, and is now used very largely. In this process the sensitive silver salt is held in suspension in either collodion or gelatin. The collodion emulsion may be made by dissolving in one portion of collodion a solution of zinc bromide, in another a solution of silver nitrate, and then thoroughly mixing the two portions. The gelatin emulsion may be prepared by bringing into solution the gelatin with potassium bromide, while a solution of silver nitrate to which some ammonia is added is gradually poured into the liquefied solution of gelatin. These emulsions are floated on plates and dried. Modern plates of this nature are found to be from ten to a hundred times more sensitive than the older wet plates, and have thus made possible the photography of moving objects and of those which are only dimly lighted. They also make possible the flash-light pictures by means of which instantaneous views are taken of a dark interior during the burning of a small quantity of magnesium. A large variety of developing agents are employed with the modern dry plate. Pyrogallie acid in connection with an alkali is perhaps the most common. Sodium hyposulphite is almost entirely used as the 'fixing' agent.

The camera consists of a box, either of wood or a framework of wood with a bellows-expanding body of leather, so that when closed the camera may occupy but little space and be conveniently carried. In the front of the camera is the lens, and at the back a piece of ground glass on which the image of the object to be photographed may be focused, together with an arrangement for lengthening or shortening the body of the camera. The camera should be placed so as to insure perfect rigidity when fixed, and for indoor work should be strong and steady, while for outdoor photography the camera stand should be made light so as to be easily portable, or the stand or tripod may be dispensed with altogether.

The lens is of very ancient origin. There is a lens in the British Museum which was found in the ruins of Nineveh, and during the Middle Ages the manufacture and properties of simple lenses were well understood in Europe. In general use now, four varieties of lenses are common: (1) A single lens consisting usually of a combination of two converging meniscus lenses separated by a diverging meniscus, arranged as a combination in the tube of the lens at the end nearest the camera, the convex side of the combination being toward the plate; (2) a rapid rectilinear lens consisting of a converging meniscus lens cemented to a diverging meniscus, the latter occupying the

outside position in the tube; (3) a wide-angle rectilinear lens of somewhat similar construction, having two combinations formed of meniscus lenses, but of much deeper curvature than those employed in other combinations, and placed closer together in the lens tube; and (4) the portrait lens, consisting of a back and front combination, arranged at some little distance apart, the front combination containing a double convex and a plano-convex lens cemented together, the double convex lens taking the position next the object, while the back combination consists of a double convex and a diverging meniscus lens, which are frequently mounted so as to leave a small space between the two.

In photographing an object the camera is set up, and, after the image is properly focused on the ground glass plate, the holder containing the sensitized plates, which are carried in double-backed dark frames arranged to carry two plates, each back to back, is inserted in the camera and the cover of the slide is withdrawn, exposing the sensitized plate so that it receives the picture. The shutter is then closed and the cover of the dark slide placed over the plate, which is later taken to the dark room for development.

For the bringing out or 'developing,' as it is called, of the latent image that has been produced on the sensitive plate, it is treated with various solutions; thus, in the daguerreotype the vapor of mercury is the agent used, and in the wet collodion process, as has already been mentioned, the development is effected by ferrous sulphate or pyrogallie acid. In the case of the dry plates, a developer, prepared by adding one part of a saturated solution of ferrous sulphate to four parts of a saturated solution of potassium oxalate, to which has been added a very small quantity of a solution of potassium bromide, is sometimes employed. A ferrous citro-oxalate is frequently used instead. As the plates are exceedingly sensitive, they must be developed in a dull ruby light, and the operation is accomplished by laying the plate in the developing tray, face upward, after which the liquid is run gently from one end of the plate to the other. Excellent results have also been obtained by the use of hydroquinone, eikonogen, metol, etc. These substances, when mixed with potassium bromide and sodium sulphide to act as reducing agents, produce very clear negatives. But pyrogallie acid is still most largely used as a developing agent.

For the reproduction of printed copies from the negative, a paper sensitized by dipping in a solution of silver nitrate is employed, and is then exposed to the sunlight, under the negative. The paper, which should be of some light and moderately strong quality, is first coated on the surface with a smooth layer of albumen to which either ammonium or sodium chloride has been added, and then floated in a solution of silver nitrate of varying strength, according to the condition of the negative, and of which 50 grains of the salt for every ounce of water is an average proportion. The exposure to light also varies according to the brightness of the light and the character of the negative. The print thus obtained is toned by immersion in a neutral solution of gold containing certain metallic salts, and finally the image is fixed by immersing the print in a solution of sodium hyposulphite which removes the unaffected silver salt. The final opera-

tion consists in thoroughly washing the print, after which it is ready for mounting.

The gradual disappearance or fading out of prints made with silver salts led to numerous attempts to find satisfactory substitutes, and various metallic salts have been employed for the purpose of producing permanent prints, some of which are described in the following paragraphs:

CYANOTYPE OR BLUE PRINTS. The earliest of these is perhaps the one first described by Sir John Herschel, and consisting in the reduction of ferric salts by light. Solutions of 1 part each of ammonium ferric citrate and potassium ferrieyanide in 8 parts of water are made separately and then mixed in a dark room. The paper or cloth is floated on this solution and exposed under a negative to the action of sunlight, and then thoroughly washed. This process is employed largely for copying plans by builders and architects, and the lines of the drawing appear white on a blue ground. It is much used on account of its cheapness and simplicity. A somewhat similar process, in which the ammonium ferric citrate is substituted by a solution of 1 part of uranium sulphate in 4 parts of water, yields a beautiful rich brown print.

FERROTYPE, OR TINTYPE. In this process a piece of sheet iron is japanned with black varnish and baked, after which it is sensitized with a collodion solution and exposed in a camera to the object, then developed and finally covered with some protective coating. See **FERROTYPE**.

PLATINOTYPE. The substitution of platinum for silver, originally introduced by W. Willis, has found considerable favor, owing to the fact that the prints are both richer and more permanent than those made with silver salts. The original process consisted in sensitizing the paper with a mixture of ferric oxalate and a platinum salt. Exposure to light resulted in the reduction of the ferric salt to the ferrous state, and when the ferrous salt was in solution the platinum salt was reduced by it. By floating the exposed paper on a solution of neutral potassium oxalate, which is a solvent for ferrous oxalate, the platinum salt in contact was immediately reduced to the metallic state and the image built up. Such prints were fixed by immersion in dilute hydrochloric acid, which dissolved any ferric oxalate or calcium oxalate that might be present. A second process has been introduced in which the paper is simply coated with ferric oxalate containing a small quantity of mercuric chloride, which after exposure is developed by a solution of potassium oxalate with the platinum salt. A still more recent method is one in which the paper is sensitized with a mixture of the platinum salt with sodium-ferric oxalate and sodium oxalate, and under the influence of light and the moisture of the air the reduction of the platinum salt takes place in the printing frame. Excellent results have been obtained by toning silver prints with platinum, which yields rich brown and black tones.

PHOTO-MECHANICAL PROCESSES. Methods by which photographic impressions could be reproduced by mechanical means, and so used directly on the printing press, have naturally been sought for, and have been invented. Such processes depend for the most part upon the action of light on a gelatin film impregnated with a bichromate, generally of potassium or ammonium. The processes in question may be divided into two groups.

In processes of the first group, the picture is molded in gelatin and colored by a pigment. The group includes the Woodburytype or Photoglyph and the Stannotype. In the Woodburytype a sheet of bichromatized gelatin, a highly sensitized mixture of gelatin and potassium bichromate, is prepared and a thin film exposed under a negative to a strong light and then washed to remove the unchanged gelatin that was protected from the light by the negative, and finally dried. This film is placed upon a sheet of soft metal, usually lead, and forced into it by hydraulic pressure, producing a mold of the picture, in which the dark parts are in intaglio and the light ones in relief. This mold is then inked with a solution of warm gelatin colored with pigment, and a sheet of paper laid upon it, a strong pressure exerted in a horizontal press, the excess of ink being forced out by pressure. The print is then immersed in a solution of alum, which renders the picture insoluble. The Stannotype, which is a modification of the foregoing process, consists in substituting for the lead plate a thin sheet of tin-foil properly strengthened in the back by electrotyping material. In the photo-mechanical processes of the second group, the picture is printed with ordinary printing ink from a gelatin surface, from stone, from metallic relief surface, or from an intaglio copper plate. The 'collotype' or 'phototype' processes of this group, in which the picture is printed from a gelatin surface, are represented by the *Albertype*, invented by Joseph Albert, of Munich, in 1869. This process consists of coating a sheet of plate glass with a thin film of chromatized albumen and gelatin, which is then laid face down on black cloth and exposed to light. The insoluble gelatin next to the plate adheres firmly to the glass and serves as a foundation for a second film, which consists of chromatized gelatin. The dry film is placed under the negative in a printing frame and exposed to the light until the shades of the image are visible through the glass. Next the plate is washed in water to remove the soluble bichromate, and the film hardened with chrome alum and dried. The plate is fastened to the bed of a printing press by means of plaster of paris. The *Artotype*, which is similar to the foregoing, was invented in 1878. A mixture of albumen and soluble glass is used for the foundation on which the sensitive film is afterwards placed. As such a film does not require to be hardened by light, opaque metallic plates may be used instead of a glass plate, as in the previous process. *Indotints* or *autoglyphs* are produced by processes similar to the foregoing, except that the support for the gelatin film is usually of copper slightly roughened in order to cause the sensitive film to adhere firmly. The addition of alcohol to the chromatized gelatin is said to increase the toughness and tenacity of the film. After exposure under the negative the unchanged bichromate is washed out and the plate is dried. Prints from such plates can then be taken on a power press. The heliotype process differs from the foregoing by the hardening of the gelatin film with chrome alum and the detaching of it from the support upon which it was first prepared; thus yielding, when completed, a thin sheet or skin of gelatin that is both tough and flexible, and which may be placed on a plate of zinc or attached to a cylinder when used for printing.

Excellent results in color have been obtained

in the foregoing processes by preparing several gelatin plates, each of which corresponds to a different color in the original, and these are then used for printing with colored inks. Prints have been produced in which as many as seven successive distinct colors have been used. In those processes in which the picture is printed from stone, a sensitive mixture of albumen and ammonium bichromate in water is passed over a lithographic stone which has been thoroughly polished and cleaned. The excess is carefully rubbed off and the surface of the stone dried so as to remove all traces of moisture. It is then exposed under a negative, and wherever the light penetrates to the chromatized albumen it becomes insoluble. After sufficient exposure the surface of the stone is covered with lithographic ink and washed with water so as to remove the soluble parts of the film, and then treated with the acid and gummed and printed as in ordinary lithography. The difficulty in handling the heavy stones soon led to the invention of an improved process, in which a sheet of paper, sensitized with a solution of albumen, gelatin, and potassium bichromate, was placed face down on a sheet of smooth copper, and then exposed under a negative, after which it was coated uniformly with the usual lithographic transfer ink. The paper was then floated on boiling water in order to coagulate the albumen on the film, and the unaltered gelatin which was protected by the opaque portions of the negative absorbs moisture and swells, leaving the unaltered gelatin depressed. This print, again washed and then dried, is transferred to stone by simply placing it upon that material face downward and passing it through the press.

Processes in which the picture is printed from a metallic relief surface include the ordinary photo-engravings or photo-electrotypes. In the former a plaster mold is taken of the gelatin film and a cast reproduced in type metal, when it is called a *photo-engraving*, or in copper, when it is known as a *photo-electrotype*. Among these should be included those processes of photo-etching in which the pictures are printed from zinc plates to which the design has been transferred in adhesive transfer ink from paper, similar to the transfer process referred to under PHOTOLITHOGRAPHY. The zinc plate thus obtained is then treated with acid in order to lower the white portions, producing a low relief.

Processes in which the picture is printed from an intaglio copper plate had their origin in France, and were known variously as *photo-gravures*, *photo-aquatints*, etc. These consist of gelatin relief films similar to those of the Woodburytype (see above), with certain modifications which caused the production of a grain in the relief film; thus in the case of the photogravures of Goupil, the material producing this effect is said to be pulverized glass. A mold is then made from the gelatin relief, from which a copper plate is obtained by electrotyping, from which the prints are then carefully made.

The invention of a transparent and flexible film pellicle for supporting the sensitized photographic surface was made by Hannibal Goodwin, and his application for patent was filed May 2, 1887, but the patent was not issued until September 13, 1898. The substance itself was entirely new, and the manufactured article consisted of a film support of a dried and hardened cellulosidal solution of nitrocellulose. The film must be

non-greasy, insoluble in developing fluids, insensible to heat and moisture, hard, smooth, brilliant of surface, exceedingly thin and light, and absolutely transparent. It was no easy matter to obtain all these properties in the new support, and it is only after many years that the film has succeeded in supplanting, to any great extent, glass as a supporting substance. It was a very important invention and has made possible the widespread modern employment of photography by amateurs. The roll holder, by means of which a long strip of film can be carried in a comparatively small space, was first suggested by W. J. Stillman, and has led to the modern hand camera for films, and later to the so-called system of 'daylight photography,' which still further increased and simplified the use of photography by amateurs.

APPLICATIONS OF PHOTOGRAPHY. In addition to the production of pictures of persons and scenery, photography finds extensive application in reproducing paintings and thus popularizing famous works of art. Photography is further employed in many branches of science. The micro-photographs of minute forms of life have added much to our knowledge of such organisms, and the photographs of the heavens are furnishing innumerable data that will doubtless lead to astronomical generalizations of the greatest importance. (See **ASTRO-PHOTOGRAPHY.**) The application of photography in legal matters for the purpose of showing forged signatures and establishing facts that were disputed has been of the utmost value. Photographs taken from balloons during the Boer War furnished information that proved of great value. The biographic pictures in which the effect of motion is reproduced in consequence of the successive exposure, occupying but a 250th part of a second, has brought about a revision of the opinion in regard to many forms of motion, the details of which can now be studied. And the employment of photography is constantly growing.

PHOTOGRAPHY IN LAW. The courts have generally recognized that an accurate likeness of an object or place can be reproduced by means of the art of photography, and photographs are now often an efficient means of demonstrating a fact in the trial of a cause. They are admitted in both civil and criminal cases as an aid to the jurors in their efforts to understand descriptions of places and objects which might not otherwise be presented in an intelligible manner.

By the general weight of authority a photographer has no right to print copies from a negative likeness of a person, for his own use or distribution in any way, without the person's consent. The person whose likeness is thus taken may restrain the sale of his photographs, and recover such damages as he may have sustained by reason of the sale of the copies. This is generally placed on the ground of implied contract, and sometimes of breach of confidence. The photographer owns the negative, but the person whose likeness is on it has the right to say whether it shall be used or not.

BIBLIOGRAPHY. The literature of photography is so extensive that mention can be made of but few of the many works dealing with the subject in its different aspects. In fact, many of the authorities have prepared a number of works each of which discusses a single process or phase of the subject, and these should be consulted by

the reader in search of information. The works of Abney, Robinson, Vogel, Eder, and Burton are all authoritative and valuable. The following works will doubtless be of service to the reader, although it must be understood that such a list is by no means comprehensive:

Harrison, *History of Photography* (New York, 1887); Abney, *Instruction in Photography* (London, 10th ed., 1900); id., *Photography with Emulsions* (New York, 1886); id. (with H. P. Robinson), *The Art and Practice of Silver Printing* (London, 1888); Vogel, *Chemistry of Light and Photography* (London, 1882); Dallmeyer, *Telephotography* (London, 1899); Burton, *Photographic Optics* (New York, 1891); id., *Modern Photography* (London, 1892); Lummer, *Contributions to Photographic Optics*, translated and augmented by S. P. Thompson (London, 1900); Duchochois, *Photographic Reproduction Processes* (New York, 1891); Wilkinson, *Photo-Engraving in Line and Half-Tone* (London, 1886); id., *Photogravure* (London, 1890); Bolgas, Talant, and Senior, *A Handbook of Photography in Colors* (New York, 1900); Woodbury, *The Encyclopædia of Photography* (London, 1892); Wilson, *Cyclopaedic Photography* (New York, 1894).

Among the more prominent English and American annuals may be mentioned: *The American Annual of Photography* and the *Photographic Times-Bulletin Almanac* (New York), and *The British Journal of Photography Almanac* (London). The principal current periodicals are the *Photographic Times-Bulletin* (New York), *Wilson's Photographic Magazine* (New York), *The Photo-Miniature* (New York), *Camera Work* (New York), *Camera Notes* (New York), *The Photo-Beacon* (Chicago), *Camera Craft* (San Francisco), *The Professional and Amateur Photographer* (Buffalo), *The Photo-Era* (Boston), *The British Journal of Photography* (London), *The Amateur Photographer* (London), *Photography* (London), *The Photographic Art Journal* (London).

PHOTO-LITHOGRAPHY. See **LITHOGRAPHY.**

PHOTOMETRY (from Gk. φῶς, *phōs*, light, + -μετρία, *-metria*, measurement, from μέτρον, *metron*, measure). The science of comparing the intensities of sources of light. It is impossible at the present time to measure the intensity of a source of light in terms of any absolute standard, i.e. in terms of watts; and therefore it is customary to compare the intensity with that of a standard source of light, and for this purpose various standards of white light have been proposed and used, but none have been completely satisfactory. These will be found discussed below. The 'intensity' of any source of light is defined to be the amount of light emitted through a cone whose solid angle is unity. The 'flux of light' is the amount of light emitted through any sized solid angle. The 'illumination' of any illuminated surface is the flux of light falling upon it divided by its area. The 'brightness' of a source of light, if it is a surface, is the intensity divided by the area of the surface. See an article by Crew, *Astrophysical Journal*, vol. vii., p. 298, 1898.

If a surface is illuminated by a small source of light, its illumination varies directly as the intensity of the source and inversely as the square of its distance from the surface. (See **LIGHT.**)

The intensities of two sources may be compared, therefore, by allowing two portions of the same surface to be illuminated by them. If the illumination over these two portions is the same apparently to the eye, the intensities of the two sources are in the same ratio as the squares of their distances from the surface. There have been several devices invented to secure the illumination of two portions of the same surface by the two sources. These instruments are known as photometers and are described below. The problem of comparing two colored sources of light, or of comparing the intensities of the colors produced by two sources of white light when dispersed by a prism, is practically the same as that just discussed, but requires a photometer adapted for this purpose. See SPECTROPHOTOMETRY.

PHOTOMETERS. Most photometers are based upon the law of the inverse squares and enable us to compare the relative intensities of two lights by finding at what distance they furnish equal illumination. There are also other photometers, but those depending on the equality

FIG. 1.

of illumination are by far the most extensively employed. The earliest photometer was devised by Bouguer and consisted of a vertical screen at right angles to a partition. On either side of the partition was placed a light so that it would illuminate one side of the screen. These lights were then adjusted until the two halves of the screen appeared of equal brightness. The distances of the lamps or lights from the screen were measured, and a proportion formed according to the law of the inverse squares. The screen, which was at first opaque, in later instruments was supplanted by one of ground glass, oiled paper, or other translucent material. An instrument based on the same principle which is in some respects modified is shown in the accompanying diagram (Fig. 2). Here A and B are the two illuminants,

FIG. 2.

as before, and the rays of light fall on the surfaces of the prism C. The two lights are moved so that the surfaces of the prism appear equally illuminated to the eye of the observer at E. A simple and effective photometer was devised by Lambert in 1760, but as it was used extensively by Rumford some years later, it is known by his name. It consists of a vertical screen with a white surface, in front of which stands a cylindrical stick. The lights to be compared are placed in front of this stick, so that each will cast a shadow on the screen. These shadows represent the amount of light furnished by but one of the sources, consequently by varying the distances of the lights from the screen a position can be obtained where they furnish shadows of equal intensity. Measuring the distance of the lights from the screen, squaring these numbers, and forming a proportion, we can again compare

the intensity of the two illuminants. A second screen with an aperture cut in it may be placed parallel to the first with the lights in front of it

FIG. 3. RUMFORD PHOTOMETER.

and some little distance apart, so that each illuminates the screen by means of rays sent through the aperture. The two separate spots of light on the screen can be made equal by adjusting the lights and their comparative intensity computed as before. The photometer in most general use is that of Bunsen, where the two lights to be compared, A and B, are placed at the

FIG. 4. BUNSEN PHOTOMETER.

opposite ends of the apparatus and a screen, C, whose face is perpendicular to the incident rays can be moved to and fro between them. This screen is made of a sheet of white paper with a central spot, d, produced by oil or grease, which appears bright on a dark ground by transmitted light, and dark on a light ground by reflected light. When the transmitted and reflected lights are equal in intensity the spot should disappear and the surface of the paper appear uniform, but in actual practice this condition is not realized. The sheet of paper is usually mounted in a box or carriage with mirrors or prisms enabling the observer to see simultaneously both sides of the paper, and is moved along a scale between the two lights, which is either graduated in units of length or indicates candle power direct. The reading is taken when the spot disappears as nearly as possible, and the candle power or relative intensity is determined as in the other cases. The arrangement of the lights, of course, varies in different forms of the instrument, as does also the construction of the box carrying the screen, but in general the results do not possess a greater accuracy than 4 or 5 per cent. The Rumford photometer cannot be depended upon closer than 8 or 10 per cent., but in all classes of photometric work much depends upon the observer.

The most modern and accurate photometer is that of Lummer and Brodhun, in which the central spot disappears entirely when the lights are of equal intensity. This is accomplished by the use of two right-angled prisms, one, E, with its hypotenusal face plane, the other, F, with this face ground spherical except in the centre, where a circular spot is perfectly plane. The two prisms are then placed with their hypotenusal sides adjacent, but separated except at the centre,

where the plane ground surface of the second prism is in contact with that of the other. The lights are placed at opposite ends of the apparatus, as in the case of the Bunsen photometer,

FIG. 5. PLAN OF LUMMER-BRODHUN PHOTOMETER.

and the rays fall on a central opaque screen, C, from which they are reflected to mirrors, D and D', and then to the faces of the prism. The rays from B entering the prism F, which has a spherical surface, undergo total reflection, except at

other. If the illuminant to the left of the observer, for example, is of greater intensity, then we have a bright spot on a dark ground, and reversing the conditions the dark spot surrounded by light. When the lights are of equal intensity the spot entirely disappears and the field is uniform. The Lummer-Brodhun screen is usually mounted on a carriage which can be moved along a scale and which is easily reversed as a check on the observations. It also has a telescope, H, to observe the surface of the prism, which is a distinct advantage, as it permits the use of one eye and enables the observer to decide more accurately when the spot disappears.

The main difficulty in photometry is the comparison of lights of different colors, as then the determination of equally illuminated surfaces is an extremely difficult matter. For this purpose Rood, employing a principle first made use of by Whitman, has devised a 'flicker photometer' in which the light from two different sources is pre-

FIG. 7. LUMMER-BRODHUN PHOTOMETER ARRANGED FOR TESTING INCANDESCENT ELECTRIC LAMPS.

the central portion (d), where the glasses are in contact. Therefore, only the rays passing through this central portion enter the second prism, E, and produce a spot of light of elliptical shape on its opposite surface. The rays from the other source of light, A, are reflected into

sent alternately to the eye in rapid succession. When the flicker disappears, it is shown that the light coming from one source is equal in intensity to that from the other.

FIG. 6. LUMMER-BRODHUN PHOTOMETER.

the prism E, and by total reflection at the hypotenuse are brought to the third face of the prism, except those falling on the surface of contact, which enter the prism F. Consequently we have the surface of the prism E nearest the observer illuminated in part by the rays from one source of light and in part by rays from the

STANDARDS OF LIGHT. The question of standards of light possesses an intimate and important connection with photometry, and is a subject which is still attracting much attention from physicists. Until the International Congress on Electrical Units in 1883 adopted as the absolute standard the amount of light emitted by a square centimeter of melted platinum at the point of solidification, there was no really scientific unit in general use. Numerous forms of candles and lamps were employed, but little reliability could be placed on the results obtained in such tests; and they did not form a satisfactory basis for subsequent or independent determinations. In France the standard used in photometric tests was the Carcel lamp, which burned purified rapeseed oil. The lamp was constructed according to certain fixed specifications, but it did not appeal to scientific men universally as an accurate standard. Candles have been used for a number of years as standards in spite of their many shortcomings; and we are now accustomed to have our electric and other lights rated in candle power. The candle in use in the United States

and England for photometric tests is the standard spermacetti candle, which burns 120 grains of material per hour and six of which weigh one pound. When this is prepared according to certain specifications as to size and form of wick, and burns with a flame 45 millimeters in height, the light emitted is considered unity. The stearin star candle was used in France and a somewhat similar candle in Germany, while a paraffin candle known as the *Vereinskerze* on account of its being adopted by the Union of German Gas Men was used in Germany and Austro-Hungary. The standard now commonly used in Germany is the acetate of amyl lamp of Hefner, which can be so adjusted as to be equivalent to the English candle. In practical photometry secondary standards consisting of incandescent lamps which have been standardized by comparison with some fundamental standard are used, and ordinary lamps are tested by reference to them.

Consult: Palaz, *Industrial Photometry*, translated by Patterson (New York, 1894); Stine, *Photometrical Measurements* (ib., 1900); *Record of the International Congress of Physicists*, 1900 (Paris, 1901).

PHOTOPHONE (from Gk. $\phi\acute{o}\varsigma$, *phos*, light + $\phi\acute{o}\nu\eta$, *phoné*, voice), **RADIPHONE**, or **SPECTROPHONE**. Instruments in which radiant energy in the form of light acts to produce sound were devised by Prof. Alexander Graham Bell (q.v.) in conjunction with Sumner Tainter. The invention of the photophone arose from the employment of Willoughby Smith of selenium (q.v.) as a resistance medium in testing submarine cables. It was found that the electrical resistance of selenium varied considerably, and the discovery was made that this was due to the action of light, which lessened the resistance. Werner Siemens (in 1875) produced some extremely sensitive varieties of selenium, and in some of his experiments the resistance on exposure to light was found to be only one-fifteenth of what it was in the dark. Professor Bell substituted the telephone for the galvanometer and used intermittent flashes of light to produce a succession of changes in the conductivity of the selenium, corresponding in frequency to the musical vibrations within the limits of hearing, as it appeared to him that all the audible effects obtained from electricity could also be produced by variations in the light acting on selenium. He perceived the effect could be produced at the extreme distance at which selenium would respond to the action of a luminous body, and that this distance could be indefinitely increased by the use of a parallel beam of light, so that it would be possible to telephone from one place to another without a conducting wire, were apparatus devised by which variations could be produced in a parallel beam of light, corresponding to the variations in the air produced by the voice. After a number of experiments in which the resistance of the selenium cells was greatly reduced and other difficulties overcome, a form of photophone was devised in which light reflected from a plain mirror of flexible material, such as silvered mica or a microscope cover glass, against the back of which the speaker's voice is directed, was caused to vibrate with a frequency corresponding to that of the diaphragm itself. For reproducing sound at a distance sunlight or any other powerful light may be used, and a large beam is concentrated by means of a lens upon the diaphragm

mirror, which after reflection is again rendered parallel by means of another lens. The beam is received at a distant station upon a parabolic reflector, in the focus of which is placed a sensitive selenium cell, connected in a local circuit with a battery and a telephone. The loudest effects were produced by rapidly interrupting the beam of light by a perforated rotating disk, revolving over the face of another perforated disk, with holes corresponding. These experiments led to others with substances other than selenium, and without the use of telephone or battery. A thin sheet of hard rubber was held close to the ear while a beam of intermittent light was thrown upon it by a lens, the result being the production of a musical note, and this effect was intensified by arranging the hard rubber as a diaphragm and listening through a hearing-tube. The conclusion was reached that sounds could be produced by the action of a variable light from substances of all kinds when in form of thin diaphragms. Subsequently Professor Bell concluded that sonority under the influence of intermittent light was a property of all matter. Various experiments with different fibrous and porous materials, such as cotton-wool, worsted, silks, sponge, lampblack, etc., indicated that lampblack may be substituted for selenium in an electrical receiver. In France, M. Mercardier passed an intermittent beam from an electric lamp through a prism and found a difference in the audible effects in different parts of the spectrum. These experiments were repeated by Professor Bell, who ascertained that sounds were obtained in every part of the visible spectrum excepting the extreme half of the violet, as well as in the ultra-red. A continuous increase in the loudness of the sound was observed upon moving the receiver gradually from the violet into the ultra-red, corresponding exactly with the proportion of heat in different parts of the spectrum, and showing that these effects are produced by the heat which accompanies light. Beyond this point the sound began to decrease, and then stopped so suddenly that a very slight motion of the receiver made all the difference between almost maximum sound and complete silence. Experiments with various substances led to the conclusion that the nature of the rays that produce sonorous effects in different substances depends upon the nature of the substances that are exposed to the beam, and that the sounds are in every case due to those rays of the spectrum that are absorbed by the body. These considerations led Professor Bell to construct a new instrument for use in spectrum analysis, which he termed a 'spectrophone.' The eyepiece of a spectroscope was removed and sensitive substances were placed in the focal point of the instrument behind an opaque diaphragm containing a slit. These substances are put in communication with the ear by means of a hearing-tube, and if we smoke the interior of our spectrophonic receiver and fill the cavity with peroxide of nitrogen gas, we have then a combination that gives us good sounds in all parts of the spectrum, visible and invisible, except the ultra-violet. Now pass a rapidly interrupted beam of light through some substance whose absorption spectrum is to be investigated, and bands of sound and silence are observed upon exploring the spectrum, the silent positions corresponding to the absorption bands. The ear cannot compete with the eye in the examination

of the visible part of the spectrum; but in the invisible part beyond the red the method is applicable. In working in this region of the spectrum, lampblack alone may be used in the spectrographic receiver. Professor Bell stated that the spectrophone was only an adjunct to the spectroscope, but he considered that it would have a wide and independent field of usefulness in the investigation of absorption spectra in the ultra-red.

PHOTO-SCULPTURE. An ingenious use of photography to assist a sculptor in modeling portrait statues, or fac-similes and reduced reproductions of other statues, invented by M. Willème in 1867. The subject stands in the centre of a circular chamber, and is simultaneously photographed by no less than 24 cameras, arranged at equal distances round the chamber. The 24 photographs are subsequently made available in the sculptor's studio, where the clay model is arranged on a frame capable of being turned round. A magic lantern throws the outline of photograph No. 1 on a screen in front of the artist, who by means of a pantograph brings this outline to bear on the clay in its first position. The model is then turned round one twenty-fourth of a revolution, and the outline of photograph No. 2 is taken advantage of. Thus the modeler works his way in 24 changes round the model, and the likeness or fac-simile or reduced figure of the original is or should be complete. The method has been also applied to the taking of medallions and the like.

PHOTOSYNTAX (from Gk. $\phi\omega\varsigma$, $ph\acute{o}s$, light + $\sigma\acute{\upsilon}\nu\tau\alpha\acute{\xi}\varsigma$, $syntaxis$, arrangement. The first special term proposed (1893) to designate the process of the manufacture of carbohydrate food by green leaves under the influence of light. See PHOTOSYNTHESIS.

PHOTOSYNTHESIS (Neo-Lat., from Gk. $\phi\omega\varsigma$, $ph\acute{o}s$, light + $\sigma\acute{\upsilon}\nu\theta\epsilon\sigma\iota\varsigma$, $synthesis$, combination). The process by which the green parts of plants construct carbohydrates under the influence of light. Carbohydrates are substances like sugars, starch, etc., which serve as the most important foods, both for plants and animals. The materials out of which the plant builds these foods are carbon dioxide and water. The idea current in the middle of the last century, and persisting even yet, that plants obtain their carbon compounds chiefly from the soil is erroneous. Few of the materials absorbed from the soil are fairly to be considered as foods. Carbon dioxide is present in normal air in minute quantities, usually less than three parts in 10,000. Yet it is absorbed by the aerial parts of plants, particularly the leaves, in sufficient quantities, because it finds its way by diffusion at high speed through the minute openings in the epidermis (stomata, q.v.) into the intercellular spaces which are bounded by moist cell walls. (See AERATION.) In the water of these it readily dissolves and diffuses to the interior of the cells, where under proper illumination it is being used as rapidly as it can be absorbed. (See ABSORPTION.) It is not possible for the carbon dioxide to be dissolved in any considerable quantity by the superficial cells themselves, since the walls of these are more or less completely waterproofed to prevent evaporation. This effectually prevents solution and consequent diffusion of the carbon dioxide. The water necessary for food-making is obtained by absorption (q.v.) through the roots. The

amount requisite for this purpose, however, is very small in comparison with the great quantities needed to replace that lost by evaporation. (See TRANSPIRATION.) Carbon dioxide does not merely dissolve in the water, but enters into loose chemical union with it, producing carbonic acid, which is highly unstable, as compared with the very stable carbon dioxide. Therefore it may be readily decomposed and its components rearranged to form a new substance. This is done by the living protoplasm.

The necessary energy is only obtainable when the plant is supplied with light of sufficient intensity. To obtain the requisite energy plants have developed in the cells lying near the surface minute protoplasmic bodies called chloroplasts, holding various green and yellowish pigments called collectively chlorophyll (q.v.). These pigments absorb only certain wave lengths of light, as shown in the accompanying absorp-

FIG. 1. THE ABSORPTION SPECTRUM OF CHLOROPHYLL. The most important absorption bands are the three regions near the B, C, and D lines. The absorption to the right of the F line is faint and not easy to resolve into three bands. It seems to be due mainly to carotin.

tion spectrum (Fig. 1). They derive their sole significance from their association with the living protoplasm, or enzymes (q.v.) produced by it. Like chemical action may be produced by protoplasm when energy is supplied to it in other ways, or when radiant energy of different wave lengths than that absorbed by chlorophyll is obtained. Thus certain bacteria containing purple pigments absorb some of the invisible ultra-red rays, and these organisms are said to produce carbohydrates.

It is possible to determine in some measure the influence of light waves of different lengths. It appears that the most efficient wave lengths are those which appear as red, orange, and yellow to our eyes. It has been clearly shown that absorbed light supplies the energy and that the chloroplasts do not act merely as a screen to cut off injurious or useless radiations, a theory which was once maintained with some vigor. The intensity of light adequate for photosynthesis approaches that of the brightest diffuse daylight. No plants are able in nature to secure sufficient carbon dioxide to utilize all the energy obtained from direct sunlight, though many of them are adapted to such conditions. Photosynthesis is nearly proportional to the intensity of the light, and though it is observable by proper methods in twilight, it has not yet been observed in so weak illumination as full moonlight. Artificial lights of various kinds are efficient in proportion to their intensity. Horticultural experiments in the United States and England have shown that electric light may be used for forcing certain plants in winter to a more vigorous development of foliage and vegetative organs. See ELECTRO-CULTURE OF PLANTS.

Scarcely any two cells of the plant receive the same amount of light. Those, therefore, which lie on the upper side and are first reached by the light are in the most favorable position for photosynthesis. As many as possible are developed by

leaves in this position. Indeed, the palisade region (see LEAF) depends for its mode of development on the action of light. The internal cells, receiving only that which has passed one or more external layers, work at a slower rate, although they are usually better situated for receiving an adequate supply of carbon dioxide. Window plants, receiving the light only from a very limited portion of the sky, at most 30 to 50 per cent., are usually more or less starved, because the energy received is inadequate in amount for the necessary food-making. A comparison of the total energy received by the leaf and the amount stored in the carbohydrates formed shows that a relatively small amount of the kinetic energy has become potential in these compounds. Inability to determine the exact quantity of carbohydrate formed and to separate the energy absorbed by the chloroplasts from that absorbed by the other portions of the plant make such computations uncertain. From them, however, it appears that 1 per cent. or less of the total energy received by the leaf reappears in the starch of starch-producing leaves. The products of photosynthesis are probably unlike in different plants. Starch is often spoken of as the chief product of this process. It is probably not only a secondary product of photosynthesis, but it is certain that many plants do not form it at all. Most of the larger seaweeds, for example, make other carbohydrates and much of the carbohydrate food in the ordinary land plants is in the form of sugars, cellulose, gums, etc.

Practically nothing is certainly known of the details of the process of photosynthesis or of its first product. Several theories have been proposed; the most plausible is that of Bayer, which has recently been receiving substantial support, although it is by no means yet clearly established. According to this theory the rearrangement of the elements of carbonic acid (H_2CO_3) results in the formation of formaldehyde (CH_2O) with the elimination of oxygen (O_2). After the production of formaldehyde it is condensed (or 'polymerized') into one of the simpler sugars, such as glucose ($C_6H_{12}O_6$), which could be formed by the proper union of six molecules of formaldehyde. This again could be polymerized to form cane sugar, and cane sugar has been shown to be one of the early products of photosynthesis in a number of ordinary leaves. Starch, which is a very complex carbohydrate, must result from further compounding, and therefore can be looked upon only as a still more remote product. Some of the supports for Bayer's hypothesis are as follows: First, green leaves and even uninjured seedlings have been supplied directly with glucose, with the result that they nourish themselves therewith and store up reserve starch; second, it has been possible to supply one of the products intermediate between formaldehyde and glucose, namely glycerose ($C_3H_6O_3$), to starved plants in the absence of CO_2 , with the result that they nourish themselves and store up starch; third, formaldehyde, though under ordinary conditions a violent poison, has been supplied at the moment of its formation to an alga and the plant nourished thereby; fourth, formaldehyde has recently been detected in the green leaves of active plants; fifth, formaldehyde is produced from CO_2 in light in liquid containing leaf-enzymes and chlorophyll, though no living protoplasm is present. Such experiments, while not conclusive,

strongly support the idea that formaldehyde is the first product of photosynthesis.

The by-product of photosynthesis, oxygen, is nearly equal in volume to that of the carbon dioxide absorbed. On the average it is a little less, but in many experiments is at least 8 per cent. greater. In such cases the extra oxygen may be derived from the decomposition of other substances in the plant, since it is impossible to distinguish all sources of the evolved oxygen, which is always given off in the neutral (O_2).

It is not possible to ascertain exactly the amount of carbohydrates made under given conditions, since an indeterminate amount is used at once in the making of other more complex proteid foods, and still other indeterminate quantities are lost from any given region by migration. The net product has been determined in the sunflower as 1.6 to 1.8 grams of starch per hour per square meter; in the gourd, 1.5 to 1.7 grams; in the bramble, by a different method, 1.54 grams. The accumulation of the products of photosynthesis never reaches such a point in the normal plant that it interferes with the process. By artificial means, however, this result may be brought about. Since the supply of energy to a well-illuminated plant is more than sufficient to enable it to utilize all the carbon dioxide which can enter the cells under the usual small partial pressure of carbon dioxide, increasing the pressure of this in the atmosphere, and therefore supplying a greater quantity to the living cells, increases the amount of carbohydrates produced. This increase is almost proportional to the relative increase of CO_2 , up to a point at which this gas retards other functions. An increase of CO_2 in the atmosphere from 3 parts in 10,000 to 600 or 800 parts proves beneficial for photosynthesis. Variations in other conditions, however, may so greatly affect this that inconsistent results may be obtained from experiments.

The rate of photosynthesis is affected by the temperature, increasing with a rising temperature to an optimum, which is not far from the optimum for growth. Yet it must be remembered that many plants flourish, and therefore may make food, at very low temperatures, e.g. the alga in Arctic waters, or at very high temperatures, e.g. alga in hot springs. In conifers, photosynthesis has been reported as occurring at temperatures even below $0^\circ C$. Though the leaves and surface tissues of plants are especially liable to lose water, and therefore to become flaccid, no interference with photosynthesis results.

PHOTOTAXIS (Neo-Lat., from Gk. $\phi\acute{o}s$, *phōs*, light + $\tau\acute{\alpha}\xi\iota\varsigma$, *taxis*, arrangement, from $\tau\acute{\alpha}\sigma\sigma\epsilon\upsilon$, *tassein*, to arrange). (1) In animals, control of the direction of locomotion by light. Like the unicellular plants, the Protozoa as well as higher animals may migrate in a direction determined by that of the rays of light. According as the migration is toward or from the source of light, we can distinguish positive and negative phototaxis. The flagellate Infusoria (*Chilomonas* and *Euglena*) will move toward the light, crowding together on the illuminated side of the vessel. *Amoeba* has been observed by Davenport to be strongly phototactic, showing that such responsiveness is a general property of protoplasm, the result of chemical changes produced by light. Ciliate infusorians are not markedly phototactic. Cells containing such different kinds of pigment

as the chlorophyll of plants and the retinal pigment of the eyes of arthropods respond to the action of light in a similar way, this response being an adaptive one. A striking example of phototaxis in pigmented cells (chromatophores) is described by Keller. He has discovered that the dark color of the (illuminated) skin is due to the rich branching at the base of the epidermis of black pigment cells lying deep in the cutis. In the dark, the pigment granules stream out of the branches into the cell-body, but the branches themselves are undisturbed. So long as the black pigment has this central position, the skin appears whitish. The light, on the contrary, causes the pigment, which is probably carried passively in the plasma, to move centrifugally. (See PIGMENT.) Hydra was observed by Trembley to wander toward the light, and this is of advantage to the animal because many of the Entomostraca on which it feeds are also phototactic. So also is the starfish. The phenomenon is especially marked in bilateral animals, such as planarians, annelids, crustaceans, flies and many other insects, mollusks, and vertebrates. As Davenport states, animals which live in shady places or in the dark are negatively phototactic, i.e. shun the light, while those living in the light are positively phototactic. The house-fly is well known to be phototactic, but its maggot shuns the light. Butterflies, says Davenport, are attuned to a high intensity of light, moths to a low intensity, so that bright sunlight, which calls forth the one, causes the other to retreat. On the other hand, a light like that of a candle, so weak as not to stimulate a butterfly, produces a marked response in the moth. The males and females of ants have been observed while mating in the air to be strongly phototactic, but after that period they show themselves neutral (Loeb). The larvae (nauplii) of barnacles as well as other pelagic animals rise to the surface of the sea during the night, but descend before the strong sunlight. Temperature also affects phototaxis; a low temperature causes several of the normal responses, while under a high temperature it is accelerated; also Loeb has found that a concentrated medium, as when the water is rendered more salt, acts as the lower temperature. It is thought that, while in the retina of the eye the protoplasm is specialized for perceiving light, there is some evidence that in the eyeless animals the whole surface of the body contains such light-perceiving substances. This is well known to be the case with the earthworms, and perhaps with the oyster, Pholas, Unio, etc. The pelecypod Psammobia, the blind Protens of caves, and Triton cristatus when blinded, are irritated by rays of light, especially the blue rays, falling on the skin. Consult Davenport, *Experimental Morphology*, part i. (New York, 1897), which contains a full bibliography. Compare TROPISM.

(2) In plants, the sensitiveness to illumination. This may be fundamentally the same as heliotropism (q.v.). The effect of light upon the organism may be to accelerate or retard the movements of the motor organs on the illuminated side, this causing the body to be rotated until both sides are equally illuminated (see CHEMOTAXIS and CHEMOTROPISM), when any progress will then necessarily be toward or away from the source of light. Organisms which approach the source of light are said to be posi-

tively phototactic, those which recede from it negatively so. The same organism may show successively both forms of response in light of different intensity. For instance, *Euglena viridis* is positively phototactic in weak light, but negatively so in strong.

PHOTOTHERAPY (from Gk. φῶς, *phōs*, light + *θεραπεία*, *therapeia*, cure, from *θεραπεύειν*, *therapeuein*, to cure, from *θεράπων*, *therapōn*, attendant). Treatment of disease by means of light. The method of applying light for therapeutic purposes, devised by Dr. Niels R. Finsen, of Copenhagen, about 1896, is founded on the following data: (1) The bactericidal property of the chemical rays of light; (2) the power of the chemical rays of light to produce an inflammation of the skin (sunburn, *erythema solare*); (3) the power of the chemical rays of light to penetrate the skin. The violet and ultra-violet rays of light obtained from the sun or from an electric arc-lamp will, in a few hours, kill plate cultures of *Bacillus prodigiosus* at a great distance. The so-called sunburn is not a burn. If sunlight or electric light be passed through a layer of distilled water so arranged as to cut out the ultraviolet rays (the dark rays of heat), the resulting skin-inflammation is as great as if the light were uncontrolled. If sunlight be thrown upon the skin through a glass screen which cuts out the violet and ultra-violet rays, there is no resulting inflammation. Again, if small sealed bottles containing muriate of silver be placed under the skin of some animals kept in the dark, and of some animals exposed to the sun, if the tubes be removed an hour later, it will be found that the muriate of silver is blackened in the cases of the animals which were exposed to the sunlight, but not in the cases of those kept in the dark. It is shown by experiment that the chemical rays of light penetrate more easily in bloodless tissues than in those filled with blood. In a piece of sensitized paper put against the back of a man's ear upon the front of which the blue and violet rays are allowed to fall for 5 minutes, no reaction takes place. If the paper be replaced and the ear be compressed tightly between two glass plates and exposed again to the same light, the paper will be blackened after 20 seconds' exposure. In the treatment of patients, sunlight is used in the summer, when the sky is bright, but otherwise the light of electric arc-lamps of 50 to 80 amperes is employed. Concentration of the light is necessary to render it powerful as a bactericide. To avoid burning the skin, the light must be colored. To make the sunlight strong and cool Finsen devised a special apparatus, consisting of a lens about 20 to 40 centimeters in diameter. The lens, composed of a plain glass and a curved one, is framed in a brass ring, with a bright blue, weak ammoniacal solution of sulphate of copper between them. The water absorbs the ultra-red rays and, being blue, it excludes much of the red and yellow rays. The excluded heat rays have little bactericidal power; whereas the blue, violet, and ultra-violet rays are but slightly impaired in chemical or bactericidal power. The lens is so hung that it can be raised and lowered as well as turned on a vertical and horizontal axis, by which means it can be placed perpendicularly to the sun's rays, and at such a distance as to make the light strike the diseased area. For concentrating the electric arc-light Finsen devised an

apparatus consisting of lenses of quartz framed in two brass tubes, telescoping the one within the other. Quartz allows the ultra-violet rays (even those of very short wave-length) to pass through it much more easily than through glass, and these rays from the electric light are of less length than those from sunlight. Facing the lamp are placed two lenses having together a focal distance of 12 centimeters. At this distance from the lamp, those lenses will concentrate and render parallel the divergent rays from the lamp, and direct them through the brass tubes, at whose distal end they strike two quartz lenses. These lenses concentrate the parallel rays and converge them till they are united about 10 centimeters beyond the outer lens. The space between these latter lenses is filled with distilled water which absorbs the ultra-red rays, but does not impair the blue, violet, and ultra-violet rays. Surrounding this end of the apparatus is a mantle, through which cold water flows to prevent boiling of the distilled water between the lenses. In spite of all this precaution, the light is still too warm, and the skin must be cooled to avoid burning. This is effected by an apparatus consisting of a plate of quartz and a plain convex lens of quartz, both fitted into a conical brass ring, which carries two small tubes and four arms. To each arm is fastened an elastic band by means of which the apparatus is pressed against the skin. Cold water is run into one tube and out of the other, and thus the skin is cooled so that it can tolerate the strongest light. The pressure of the plano-convex lens on the skin renders it anæmic, thus fitting it for the easy penetration of the chemical rays. A small area of the skin is treated for an hour each day. The skin swells and becomes red, and a bulla may appear; but sloughing has not resulted. During the application the nurses are obliged to wear dark glasses to protect their eyes from the brilliant light. Dilatation of cutaneous vessels by the violet rays may continue for six months. Many diseases of supposed bacterial origin have been treated by this method, but cures have resulted only in cases of *lupus vulgaris*, *lupus erythematosus*, *alopecia areata*, and *carcinoma*. The greatest success has been reached in cases where there was an absence of scarring, of pigmentation, of great vascularity, of great depth below the surface, of involvement of eyelid or mucous membranes, or of great extent of lesion.

The number of patients at Finsen's Institute has increased from seven in 1897 to an unnumbered clientèle, with over a hundred on a waiting list. A Brooklyn, N. Y., physician has opened an institute for Finsen's treatment. The Roentgen rays (q.v.) penetrate to deep layers not reached by sunlight or electric light. Consult Morris & Dore. "Finsen's Light Treatment of Lupus and Rodent Ulcer," in *British Medical Journal*, February 9, 1901.

PHOTOTROPISM (from Gk. φῶς, *phōs*, light + τροπή, *tropē*, a turning, from τρέπω, *trepein*, to turn). A sensitiveness of plant organs to light, by virtue of which they bend to assume definite positions with reference to the direction of light incident upon them. See HELIOTROPISM.

PHRANZA, frän'zä, or **PHRANZES**, frän'zäs (Gk. Φραντζή, *Phrantzē*), GEORGE (1401-78). A Byzantine historian, born at Constantinople. He was secretary to the Emperor, Manuel II.,

and held other high offices, but at the fall of Constantinople was obliged to flee, and ended his days in an Italian monastery, where he wrote his valuable *Chronicle*, embracing the period of Byzantine history from 1259 to 1477. It was printed in Vienna in 1796, and translated into Latin in 1838.

PHRASE (Lat. *phrasis*, from Gk. φράσις, manner of speech, from φράζειν, *phrazein*, to declare). The name given, in music, to the simple motives containing in themselves no satisfactory musical idea, which enter into the composition of every melody containing a perfect musical idea, e.g.

The phrase most usually consists of two measures; in compound time it may be comprised in one measure, and an extended phrase is one which contains three measures. In the more simple and regular forms of musical composition, two phrases unite to form a section, ending in a cadence, and a perfect musical idea is formed of two such sections terminating, the first with the dominant, the second with the tonic harmony. See FORM.

PHRASING. The proper rendering of musical phrases. (See PHRASE.) A musical composition is analogous to a literary one, the sentences being replaced by phrases: upon their correct interpretation depends the intelligible presentation of the whole piece. One of the most important elements of phrasing is accent (q.v.), the general principles of which will be found under RHYTHM; but in no case must an accent be so insisted upon as to break the unity of the musical phrase. On the contrary, the ordinary accent is often postponed or anticipated in order to emphasize the general effect of the phrase. For the same reason, especially in rapid passages, accents are often added; while in quick movements accents are sometimes omitted so as to give an impression of unity to a number of separate bars. Two common faults in phrasing are breaking up a group of notes which together form a musical sentence, and running together two distinct sentences. In instrumental work, especially, there is a tendency to make a break at the end of a bar; but in reality a sentence always ends on the accented division of a bar, the bar-stroke having absolutely no relation to phrasing. In vocal music the musical accents correspond with those of the text, and the phrases are, as a rule, dependent upon the lines or word sentences. Vocal phrasing, therefore, is obviously much simpler than instrumental. The signs most commonly used to indicate phrasing are the dash; the curved line, denoting *legato*; and the slur; but the interpretation of any composition is to a great extent a matter of personal appreciation and discrimination. For some helpful suggestions on the subject, consult: Ehrenfechter. *Delivery in the Art of Pianoforte Playing* (London, 1897); Goodrich, *Theory of Interpretation* (Philadelphia, 1899); Lussy, *Traité de l'expression musicale* (6th ed., Paris, 1892).

PHRENOLOGY (from Gk. φρήν, *phrēn*, heart, mind + -λογία, *logia*, account, from λέγειν, *legēin*, to say). The theory that the mind consists of a number of independent faculties, each of which has a definite localization in a region

of the brain whose size is indicative of the degree of the faculty resident in it. Franz Joseph Gall (q.v.), an eccentric Viennese physician, announced about 1796 the discovery of a system of phrenology. He asserted that he had arrived at his results empirically, having for several years examined the heads of individuals who exhibited unusual mental or moral endowments. By these examinations he made out a system of correlations between the topography of the skull and the traits. He further concluded that the size and configuration of the brain was indicated by the size and configuration of the skull. His lectures, begun in 1796, ceased at the order of the Austrian Government in 1802, his doctrines being judged to be materialistic and inimical to the truths of morality and religion. In 1804 he associated with him his favorite pupil, Johann Gaspar Spurzheim (q.v.), and the two traveled through Germany, Prussia, and Switzerland to France. In Paris, the French Institute appointed a commission to investigate their assertions. This commission reported favorably upon certain methods of dissection, etc., but regarded their main conclusions as hypothetical. In 1809 the two began publishing a large work, *The Anatomy and Physiology of the Nervous System in General, and of the Brain in Particular, with Observations upon the Possibility of Ascertaining Several Intellectual and Moral Dispositions of Man and Animals by the Configuration of Their Heads*. Gall died in Paris in 1828, and was interred with the greatest marks of respect and honor. Spurzheim came to America in 1832, but died suddenly shortly after his arrival at Boston.

The fundamental tenets of phrenology are that the brain is the material substratum of mind, that it is a multiplex structure, composed of a definite number (originally 34, now 42) of constituent organs, each of which is the seat of a particular power of the mind—a 'sentiment,' a 'propensity,' or an 'intellectual faculty.' Furthermore, phrenology teaches that these 42 organs, or pairs of organs, constitute a series of cones with their apices at the oblongata and their bases at the surface. Each prominence in the skull indicates the size of the organ just beneath it, and in that way the development of the correlated mental faculty; for this development varies directly with the volume of its brain substrate, and, conversely, the exercise of any faculty promotes the growth of its brain seat. The 'propensities' or 'passions,' situated at the lower and posterior part of the brain, are amativeness, philoprogenitiveness, continuity, adhesiveness or friendship, combativeness, destructiveness, constructiveness, acquisitiveness, secretiveness, inabitiveness, alimmentiveness, vitativeness, and conjugal love. The 'sentiments,' situated at the superior portion of the cranium, are self-esteem, love of approbation, cautiousness, firmness, benevolence, veneration, hope, ideality, conscientiousness, spirituality, and sublimity. The 'intellectual faculties,' in the anterior region, are individuality, form, space or size, weight or resistance, color, locality, order, duration, number, tune, language, comparison, causality, wit, imitation, supernaturality or wonder, human nature, and suavity. In actual diagnosis, the size of the prominence determined the degree of the faculty only when taken in conjunction with other tendencies, for one faculty might aid or inhibit the function of another.

It is scarcely necessary to say that, as a pretension to a science, phrenology is related to modern neurology as astrology to astronomy, or alchemy to chemistry. It did, indeed, serve a useful purpose in stimulating the investigation of cortical function, in instilling the principle of the dependence of consciousness upon the cerebrum, and in offsetting the extreme views of men like Magendie and Flourens, who believed that the brain functioned homogeneously like the lungs or the liver. But in the light of modern knowledge phrenology is bad psychology and bad neurology. Modern psychology does not regard the mind as a bundle of faculties. Its components are determined rather by the contributions of the various sense-organs to its structure than by the types of activity by which the psychological self seems to acquire knowledge or express its attitude. Neurologically, too, there are many disproofs of phrenology. Different skulls have a different thickness; the same skull varies in thickness in different regions; prominences on the surface do not necessarily indicate a greater size in the part of the brain beneath; there is no correlation between brain weight and intelligence; three-fifths of the gray matter of the cortex is concealed in the sulci; loss of portions of the brain by accident or disease destroys or impairs the sensory or motor functions connected with some sense department, or some association system, not some 'faculty.' Finally, the whole structure of phrenology falls with the modern investigations of cortical localization by the methods of degeneration, electrical stimulation, medullation, and extirpation. See **PHYSIOLOGY**.

PHRIXUS (Lat., from Gk. Φρίξος). The son of Athamas and Nephele. With his sister Helle he was rescued by his mother when about to be sacrificed to Zeus, and carried to Colchis upon a ram with golden fleece. On the journey Helle fell into the waters called after her, the Hellespont. The fleece of the ram, given to King Autes and hung upon the grove of Ares, was the object of the Argonautic Expedition.

PHRYGIA, frij'î-â (Lat., from Gk. Φρυγία). A country in Asia Minor, the extent and boundaries of which varied very much at different periods of ancient history. Originally, the boundaries toward the east were the river Halys and the territory about Iconium, which was the last Phrygian city; toward the south, it touched the Taurus and the Pisidian Mountains; on the north, it reached the Hellespont and Propontis; on the west, it seems to have included the Troas and Mysia, and may have held suzerainty over Lydia and Caria. Later invaders from Thrace, who occupied Bithynia and Mysia, cut this region into two parts: Little Phrygia, a somewhat indefinite region south of the Hellespont, and Greater Phrygia, which alone preserved the national character. This was bounded on the north by Bithynia and Paphlagonia, on the east by Pisidia Lyeaonia, on the south by Cappadocia, and on

the west by the maritime countries of Mysia, Lydia, and Caria. The boundaries were further modified by the Gallic invasion of the third century B.C. (See GALATIA.) Pergamene conquests added part of Southern Bithynia, including the important city of Dorylæum, under the name of Phrygia Epictetus. The Roman provincial administration divided Phrygia, attaching the northeastern part to the Province of Galatia and the western portion to the Province of Asia. Phrygia was in general a high and somewhat barren plateau, though its pastures supported immense flocks of sheep, noted for the fineness of their wool, as indeed they still are. The most fertile part was the valley of the Sangarius, but the most beautiful and populous district was the southwestern, at the base of the Taurus, where the Mæander and other streams had their rise, and here were the chief cities, Synnada, Celæna, Apamæa, Colossæ, Laodicea, while farther to the east was Antioch. The mountains and streams yielded gold; Phrygian marble was anciently celebrated, and the cultivation of the vine appears to have been extensively carried on.

The Phrygians were certainly an Indo-European race, and seem to have entered Asia Minor from Thrace, pushing into the interior from the Troad along the valley of the Sangarius, and making themselves masters of the whole tableland, and probably extending their sway over the Asiatic tribes on the coast. We hear of a race of powerful kings alternately bearing the name of Gordius and Midas, and in the mountains near the headwaters of the Sangarius are the great rock-cut tombs or façades which were associated with these rulers. The invasions of the Cimmerians (c.675 B.C.) seem to have broken their power, and henceforth they played no part in history, but fell first under the rule of the growing Lydian kingdom, then under Persia, Macedonia, Pergamum, and Rome. They seem to have been a peaceful rustic people, devoted to agriculture and cattle-raising. Their religion was an ecstatic nature worship in which the Great Mother of the Gods, Rhea or Cybele, and a male deity, Sabazius, played a great part. The orgiastic rites and wild music seem to have exercised considerable influence upon the Greeks and Romans, and we find their deities transplanted to the Western world. Consult: Ramsay, *Historical Geography of Asia Minor* (London, 1890), and especially his incomplete work, *Cities and Bishoprics of Phrygia* (Oxford, 1895-97).

PHRYGIAN CAP. See LIBERTY CAP.

PHRYGIAN LANGUAGE. The native language of the Phrygians is known partly through glosses preserved by Hesychius and other lexicographers and authors, partly through inscriptions found in the territory once occupied by this people. Tombs with inscriptions were discovered in the valley of Doghanla by Colonel Leake in 1820. Four of these inscriptions, including that on the sepulchre of King Midas, were first published by Hamilton in 1842. A number of additional inscriptions were published by Ramsay in 1883 and others copied by himself and Sterrett appeared subsequently. Many of these are in Greek, but have Phrygian additions at the end. That the additions contain formulas of execration was first surmised by Schmidt in 1869. The researches of Ramsay and Fick have corroborated

this conjecture. As Herodotus (vii., 73) and Strabo (xlvii., cexcv.) declare that the Phrygians were related to the Armenians and the Thracians, it was natural that the language should be supposed to be Armenian. That was done by Mordtmann and Gosche. A collection of 63 glosses was made by Lagarde. He concluded that the Phrygians were derived from the Thracians and that their Iranian character was proved by such words as *ἀδάμνα* and *κύρβαυτ*. There seems to be good reason for assuming that the Phrygian language belonged to the Iranian family. While most of the monuments found belong to the Roman period, there are some that have plausibly been assigned by Ramsay to the end of the eighth century B.C. If one doubtful letter is a χ rather than a ψ , as seems probable, the Phrygians apparently received their alphabet, not from the Ionians, but from the old Æolians. After the Phrygian language had been supplanted by the Greek, it still maintained itself in imprecations, believed to be more efficacious in the speech of the fathers. The same alphabet has been found at Abu-Simbel in Egypt in inscriptions that must date from B.C. 650-590 and in an inscription found in Lemnos in 1886 in an unknown language and of uncertain age. Consult: Leake, *Journal of a Tour in Asia Minor* (London, 1824); Hamilton, *Researches in Asia Minor, Pontus, and Armenia* (ib., 1842); Stewart, *Ancient Monuments of Lydia and Phrygia* (ib., 1842); Lagarde, *Gesammelte Abhandlungen* (Leipzig, 1866); *Corpus Inscriptionum Græcarum*, iii. 3810, et seq.; Schmidt, *Neue lykische Studien* (Jena, 1869); Fick, "Zum Phrygischen," in *Bezenberger's Beiträge*, xiv., 50; Ramsay, in *Journal of the Royal Asiatic Society*, xv. (London, 1883); id., in *Journal of Hellenic Studies* (London, 1882, 1884); id., in *Zeitschrift für vergleichende Sprachforschung*, xxviii. (Gütersloh, 1887).

PHRYNE (Lat., from Gk. *Φρύνη*). One of the most celebrated courtesans of antiquity. She was a daughter of Epicles, and was born at Thespie, in Beotia. She was of very humble origin, and is said originally to have gained her livelihood by gathering capers, but her beauty afterwards brought her such wealth that, when Alexander destroyed the walls of Thebes, she is said to have offered to rebuild them, if she might be allowed to inscribe on them the words: "Alexander destroyed them, but Phryne, the courtesan, rebuilt them." Being on one occasion accused by Euthias of profanation of the Eleusinian mysteries, she was summoned before the court of the Heliasts and was there defended by the orator Hyperides; but Hyperides, seeing that the verdict of the court was likely to be an unfavorable one, threw aside her veil and exposed her bosom and shoulders; the judges thereupon acquitted her, and she was carried in triumph to the Temple of Aphrodite. She served as the model for Praxiteles's Cnidian Venus, and for the Anadyomene (q.v.) of Apelles, she having, on the occasion of a festival at Eleusis, entered the sea, unclad, in the presence of the assembled throng. Her neighbors dedicated to her at Delphi a gilded statue resting on a base of Pentelic marble, the whole the work of Praxiteles. There is preserved in Athenæus an epigram in her praise written by Praxiteles and inscribed on a statue of Cupid, which he presented to her and which she dedicated at Thespie.

PHRYNICHUS, frín'i-kūs (Lat., from Gk. Φρύνιχος). A Greek tragic poet of Athens, an older contemporary of Æschylus. He won his first victory in b.c. 511 and his last in 476, when Themistocles was his *choragos*. Like Æschylus, he is said to have died in Sicily. In all the accounts of the rise and development of the tragedy, Phrynichus is ranked immediately after Thespis, and according to some critics he should be regarded as the real inventor of tragedy. He was the first to bring female characters on the stage; for the light satyr plays of his predecessors, he substituted plays on serious subjects taken both from the heroic age and from the history of his own time; and he was the first to introduce an actor distinct from the leader of the chorus, and thus to open the way for the development of the dialogue. In his works, however, the lyrical choruses still retained the principal place, and these are said to have been so celebrated that they were sung even in the time of Aristophanes. Of his plays, the most important were *Φοῖβισσαι*, which dealt with the defeat of the Persian invaders (b.c. 480), and is said to have been copied by Æschylus in *The Persians*, and *Μιλήτου ἄλωσις*, on the capture of Miletus by the Persians. According to Herodotus, the Athenians were so moved by the latter tragedy that they fined the poet one thousand drachmas for recalling to them the disasters of their kinsmen, and passed a law forbidding further performances of the piece. Only a few fragments and the titles of nine of his plays are extant. Consult: Nauck, *Tragicorum Græcorum Fragmenta* (Leipzig, 1856).

PHTHIOTIS, thi-ō'tis (Lat., from Gk. Φθιώτις). In ancient geography, the southern part of Thessaly, north of Ænis and Malis, and west of the Pagasæan Gulf. The district was famous in the epic as the home of Achilles, and from this region the Æolian colonization of Asia Minor seems to have gone forth. The population, though maintaining a Thessalian element, was considered to be Achæan. The chief cities were Phthiotian Thebes, Larisa, Lamia, Melitæa, and Thaumaci.

PHTHISIS, thi'sis. See TUBERCULOSIS.

PHYCOCYANIN (from Gk. φύκος, *phykos*, seaweed + κυανός, *kyanos*, blue). The peculiar pigment, usually bluish-green, of the blue-green algæ. See CYANOPHYCEÆ.

PHYCOERYTHRIN, fi'kō-ēr'i-thrīn (from Gk. φύκος, *phykos*, seaweed + ἐρυθρός, *erythros*, red). The red pigment of the red algæ contained in the chromoplasts, and giving the general tint of the plant body. See RHODOPHYCEÆ.

PHYCOMYCETES, fi'kō-mi-sē'tēz (Neo-Lat. nom. pl., from Gk. φύκος, *phykos*, seaweed + μύκης, *mykēs*, fungus). A group of plants which comprises, as the name indicates, those fungi most resembling the algæ. (See FUNGI.) The Phycomycetes include the black molds (Mucorales), certain insect parasites (Entomophthorales), the water molds (Saprolegniales), and a group of very important plant parasites included in the order Peronosporales. The simplest of the Phycomycetes are unicellular aquatic forms (Chytridiales) that generally live parasitically in the cells of algæ. These representatives are usually observed in a quiescent condition, in the form of thick-walled spores or resting

spore-cases, but there are motile periods in the life history when the organisms swim freely in the water. The Entomophthorales are mostly

WHITE MILDEW (*Albugo Candida*).

a, Oögonium; b, antheridium; c, oöspore; d, swarm-spores escaping from oöspore; e, swarm-spores; f, conidia; g, swarm-spores escaping from conidium; h, the same, more distinct.

parasitic on insects, preferring the Diptera and Orthoptera, a common representative (*Empusa*) being found on the house fly. Late in the summer and in the autumn dead house flies may

GRAPE MILDEW (*Plasmopara*).

a, The branching sporophores arising from the surface of the host; b, a germinating spore; c, a swarm-spore.

frequently be observed attached by their proboscæ to window panes, walls, and other sur-

faces, with a halo of yellowish powder on the surface around them. This powder is made up of spores that have been thrown off from the ends of fungal filaments, which after filling the body of the insect have grown through the segments to the exterior. The large common molds (Mucorales) are frequently called black molds because of the color of the spore-cases (sporangia), and to distinguish them from the green and yellow mildews. They are saprophytes, growing upon organic matter in damp places, the bread mold (*Mucor*) being a familiar example. The vegetative portion of the molds (mycelium) consists of conspicuous threads (hyphæ) plainly visible to the eye, which grow over the sub-

DOWNY MILDEW OF POTATOES (*Phytophthora infestans*).
Cross-section of leaf showing growth of mildew.

stratum and when possible penetrate it in all directions. The commonest fructification is a black swollen head (sporangium) containing thousands of spores, and borne at the end of an erect branch (sporangiphore). The Peronosporales are an assemblage of forms, mostly parasitic, and contain some fungi responsible for such serious diseases as the rot of potato and the downy mildews of grapes. (See paragraph *Diseases* under GRAPE and POTATO.) Another troublesome form, sometimes placed among the Peronosporales and sometimes among the Saprolegniales, is *Pythium*, the fungus responsible for the 'damping off' (q.v.) of seedlings. The water molds (Saprolegniales) have habits widely different from other Phycomycetes, being aquatic and living on dead insects, fish, and frogs, and sometimes on the living animals. They surround the body with a beautiful halo of delicate radiating filaments. These fungi sometimes cause epidemics in fish hatcheries, where they attack the mouths and gills of young trout and salmon. Consult Engler and Prantl, *Die natürlichen Pflanzenfamilien* (Leipzig, 1887—).

PHYCOPHÆIN (from Gk. *φύκος*, *phykos*, seaweed + *φαίος*, *phaios*, dusky). The brown pigment characteristically present in the cells of the brown alga. See ΠΛΕΟΡΗΥΣΕΛ.

PHYLACTERY (Lat. *phylacterium*, from Gk. *φυλακτήριον*, *phylaktērion*, safeguard, amulet, from *φυλακτήρ*, *phylaktēr*, sentinel, guard, from *φυλάσσειν*, *phylassein*, to guard). An amulet or charm worn as a protection against evil influences.

In the New Testament the name is given to a strip of fine parchment inscribed with certain passages from the Scripture (Exod. xiii., 1-10; xiii., 11-16; Deut. vi. 4-9; xi., 18-21), and inclosed in a small leathern case. This was, in accordance with a literal interpretation of Exod. xiii. 9-16; Deut. vi. 8, 9, 18, fastened by leathern straps to the forehead, just above and between the eyes, or to the left arm, at the point where the arm, hanging down, falls nearest the heart, or sometimes to the door-post.

PHYLÆ (Lat. nom. pl., from Gk. *φυλή*, *phylē*, tribe). In Greek political institutions, the tribes or clans, originally perhaps embracing all the inhabitants of a district, though in many cases there seems to have been a theory of common descent rather than residence. Among the Dorians we regularly find the three tribes, Hylleis, Dymanes, and Pamphyli; at Miletus in Ionia and at Athens we find Geleontes, Argadeis, Ægicoreis, and Hopletes, and these names recur in other Ionian communities. The most important development of the tribe was in the reorganization of the Athenian democracy by Clisthenes after the expulsion of the tyrant Hippias (B.C. 510). The four old tribes were swept away, and the whole people divided into ten tribes on the basis of the demes, in which the people were registered. The demes in each tribe were so selected that the three divisions, Mountain, Coast, and Plain, were all represented. The tribes, which were named from heroes, were Erechtheis, Ægeis, Pandionis, Leontis, Acamantis, Oeneis, Cecropis, Hippothontis, Æantis, Antiochis. The tribes were organized as corporations, and held regularly meetings, apparently at Athens, but not in their own halls. The executive officers were the Epimeletæ, and a treasurer who had charge of the property of the tribes, for as each eponymous hero had priest and sanctuary, and received a certain part of all booty in war, the tribe had to manage certain lands and investments. The tribe chose its representatives on State commissions where work was divided among the tribes, such as the repair of walls, etc. They also elected the rich men whose duty it was to provide the choruses for intertribal competition at the festivals, or other similar public duties laid upon the rich. The military organization was based on the tribal division, for each tribe furnished a regiment of infantry under a taxiarch and a squadron of cavalry under a phylarch. Though the Senate was composed of fifty from each tribe, the senators were not chosen by the tribe but by the demes, among whom they were apportioned on the basis of population.

PHYLARCHUS, fi-lär'kūs (Lat., from Gk. *Φυλαρχος*) (c.210 B.C.-?). A Greek historian. He was born probably at Naucratis, in Egypt, but spent most of his life at Athens. His great work was a history of Greece, embracing the fifty-two years between the invasion of the Peloponnesus by Pyrrhus (B.C. 272) and the death of Cleomenes III., King of Sparta (B.C. 221). His style was graphic and animated, but according to Polybius (ii., 56) he frequently falsified history on account of his passionate admiration for Cleomenes. The work was used by Troguus Pompeius and by Plutarch in his lives of Cleomenes and Aratus. The few extant fragments have been edited in Müller's *Fragmenta Historicorum Græcorum* (Paris, 1868).

PHYL'LIS (Lat., from Gk. Φυλλίς). (1) A Thracian princess, betrothed to Demophoön, the son of Theseus, who left her to go to Athens, promising to return at a certain date. When the appointed time had passed without his arrival, Phyllis killed herself and was changed into an almond tree, which put forth leaves only when Demophoön shortly afterwards returned and embraced it. (2) In pastoral poetry, a name conventionally used of a maiden or lady-love.

PHYLLOCAR'IDA (Neo-Lat., from Gk. φύλλον, *phyllon*, leaf + *καρίς*, *karis*, shrimp). A highly composite or generalized order of Crustacea, separated by Packard from the Phyllopoða. The group is represented at the present time by *Nebalia* and its allies (*Nebaliidæ*) of the North Atlantic, forming the *Leptostraca* of Claus; also by fossil forms from the Cambrian period to the end of the Carboniferous, some of which were over a foot in length, while *Nebalia* itself is about half an inch long. In *Nebalia* the

A PHYLLOCARID (*Nebalia bipes*).

body is compressed and protected in front by a bivalved carapace, closed by a weak adductor muscle, but without a hinge; the rostrum is free, movable; the eyes stalked; the eight pairs of thoracic legs resemble those of phyllopod crustacea, and the hind-body is modeled on that of a copepod crustacean such as *Cyclops*. It undergoes no metamorphosis, and is an example of the persistence of type from very early geological times.

PHYL'LOCLAD (from Gk. φύλλον, *phyllon*, leaf + κλάδος, *klodos*, branch), or CLADOPHYLL. A branch that functions, as a leaf, which it resembles in form and color. Well-known illustrations are the 'leaves' of smilax and asparagus.

PHYL'LODES (from Gk. φυλλώδης, *phyllōdēs*, leaf-like). Leaf petioles which have developed as blade-like organs that replace regular blades. They occur only among dicotyledons. Phylloides may be distinguished from true leaves by the parallel veining, and also by presenting their edges up and down (profile position). The greatest display of phylloides is found among the acacias of Australia, where nine-tenths of the numerous species have phylloides instead of true leaves. The normal blade of these acacias is pinnately compound, as is shown by their seedlings, and occasionally when older growths are subjected to unusual conditions. In the case of pitcher plants (see CARNIVOROUS PLANTS) the urns, tubes, etc., are usually regarded as hollow phylloides, the true blade being represented by the more less conspicuous lids.

PHYL'LOGRAP'TUS (Neo-Lat., from Gk. φύλλον, *phyllon*, leaf + γραπτός, *grapτος*, written,

from γράφειν, *graphein*, to write). A genus of fossil graptolites, index fossils of the Lower Ordovician rocks of North America and Northern Europe. The theca, or cells in which the animals lived, are arranged in four rows with their dorsal sides united along a common axis to form a four-bladed colony, the blades of which are at right angles to each other. See GRAPTOLITE.

PHYLLOP'ODA (Neo-Lat. nom. pl., from Gk. φύλλον, *phyllon*, leaf + πούς, *rous*, foot). An order of fresh-water Crustacea, in which the legs are broad and leaf-like, subdivided into lobes, and adapted for respiration as well as locomotion. The trunk is not differentiated into a thorax and abdomen. The eyes are usually simple or compound, and either sessile (*Apus*) or stalked (*Branchipus*), while there is a median

PHYLLOPOD CRUSTACEANS.

1. *Branchineella Coloradensis*; 2. Shell of *Estheria Belfrugi*; 3. *Lepidurus Coeui*; front and side views.

simple eye retained from the Nauplius stage. The number of body-segments varies greatly, and the body is usually protected by an ample shell consisting of two valves closed by an adductor muscle. In the group represented by *Branchipus* and the brine shrimp (*Artemia*) there is no shell. These crustaceans are very primitive, and apparently are the ancestral forms of the class Crus-

PHYLLOPODA AND LARVÆ.

Adult of *Apus acqualis*; and (a) Larva of *Apus caneriformis*; (b) Nauplius of *Artemia salina*.

tacea (q.v.), their limbs being much like the parapodia of annelid worms. A Cambrian form (*Protocaris*) is supposed to be allied to *Apus*. All the members of this order hatch in the Nauplius stage, and after a series of molts attain the adult form. The phyllopods live in pools liable to dry up in summer. Their eggs are of two kinds, summer and winter, the latter being protected by a dense shell, so that they can dry

up and live for months or years, the young hatching when the eggs are moistened by the refilling of the pools or ditches. In some species the males have not yet been found. Consult Packard, *A Monograph of North American Phyllopod Crustacea* (Washington, 1883).

PHYLLOTAXY (from Gk. φύλλον, *phyllon*, leaf + τάξις, *taxis*, arrangement). Leaf arrangement; that is, the methods in which leaves are disposed upon their axes. See LEAF.

PHYLLOXERA (Neo-Lat. nom. pl., from Gk. φύλλον, *phyllon*, leaf + ξηρός, *xēros*, dry). An insect of American origin (*Phylloxera castantriæ*), belonging to the aphid family, and which accidentally introduced into France about 1859 upon native American vines, spread through the principal vine districts of Southern Europe, causing enormous damage. It has further spread into Algeria and through Southern Russia into the adjoining countries of Asia. It has also been carried into New Zealand and South Africa, as well as portions of Australia. In the United States it was at first known only in the region of the Rocky Mountains, but was afterwards found in California, where it is confined to those vineyards in which the European vine is grown from its own roots.

The Phylloxera is indigenous to North America, where it has always existed on the wild vines. It occurs in four forms, the leaf-gall form (*gallicola*), the root form (*radicicola*), the winged or colonizing form, and the sexual form. The sexual insect lays the winter egg on the old wood. The young one hatching in the spring proceeds to a young leaf and locates itself upon the upper surfaces, gradually forming a gall about itself which projects from the lower side of the leaf. It reaches full growth in fifteen days, and fills its gall with small yellow eggs, from 500 to 600 in number. These eggs hatch in eight days, and the young migrate to all parts of the vine to form new galls. Six or seven generations of these wingless females follow one another through the summer, frequently covering the leaves with galls. At the approach of cold weather the young proceed to the roots, remaining dormant until spring. In the spring the root is attacked by a series of generations of wingless females which produce swellings upon the rootlets. During the late summer and fall some of the root-lice give birth to winged females, which escape through the soil and fly to neighboring vines, laying their eggs on the bark. From these eggs the sexual generation issues, and the life cycle is begun again. The root form, however, may proceed in successive broods for a number of years, as is the case with the European vines on which the leaf form rarely occurs. The insect is spread by the flight of the winged females, by the migration of the root-lice through cracks in the soil, and by the carrying of the leaf-gall lice by winds, by birds, and by other insects, and further by the shipping of infested rooted plants or cuttings bearing the winter eggs. The leaf form is especially noticeable upon American vines, and is common upon the wild vines. The root form is rarely seen, but is the cause of the only severe injury to the plant. When occurring plentifully, the death of the vine in a few years is certain. The root-lice first produce enlargements on the rootlets, extending their work to the larger roots. These become swollen

and broken and finally die and rot. The vine stops growing, the leaves become sickly and yellowish, and since the Phylloxera disappears from the dead roots, the cause of the death of the plant is frequently obscure. The European vine (*Vitis vinifera*) is particularly subject to the attacks of the root form, while most American vines, although frequently carrying the leaf-galls, are more or less immune to root attacks.

The remedies used for this pest are the subterranean injection of bisulphide of carbon, and the submersion of the roots by inundating vineyards at certain seasons of the year by water. The standard preventive now employed all over the world is the use of American vines as stocks upon which to graft the susceptible European varieties. The immunity of the American vines seems to be due to the thicker bark covering of the roots, and to a greater natural vigor. The chief resistant varieties of American vines are the *Æstivalis*, the *Riparia*, and the *Labrusca*. Some American vines, however, as the Delaware, are almost as susceptible as the European vines. The varieties of the *Æstivalis* most used are the *Herbemont* and *Cunningham*; of the *Riparia*, the *Clinton*, *Taylor*, and *Solonis*. Consult Marlatt, *Principal Insect Enemies of the Grape* (Washington, 1898).

PHYLOGENY (from Gk. φύλον, *phylon*, tribe + -γένεα, *-gencia*, production, from γίγνεσθαι, *gignesthai*, to become). While ontogeny (q.v.) is a term expressing the development (embryology) of the individual, phylogeny means the development or genetic history of the members of the group or class as a whole. The conception of such a process did not arise until a multitude of facts had been accumulated during the study of the embryology of different animal types, the results being further checked and complemented by the facts of paleontology. The doctrine or theory of phylogeny, then, rests (1) upon a series of life-histories of animals, including their embryonic and post-embryonic stages of development; (2) upon what we know of the geological succession of animal forms; and (3) upon the theory of descent. Phylogeny is the equivalent of genealogy, and involves the idea of blood-relationship. A genealogical tree of a single human family, when carried out through many generations, is almost indefinitely branched and subdivided, the members or descendants from the earliest human pair affording an instance of divergent evolution. The ancestral tree or pedigree of any class of animals is a matter of theory, but the facts of affinity and homology are so numerous and natural that the theory is fairly well grounded. The phylogeny of any group is an expression of one's view of classification, and since in respect to many groups there is a divergence of opinion as to the systematic position of this or that member, so the views as to the pedigree of certain classes or general groups differ with different systematists. The success of the endeavor to work out a phylogeny of any group depends very largely on knowledge of the earlier fossil forms; yet each attempt leads to the more careful study of this or that characteristic, to tracing its growth, development, and final disappearance, or replacement by a later acquired feature, while the mental discipline resulting tends to render the work of the systematist more philosophical. See PALEONTOLOGY; EVOLUTION.

PHYLUM (Neo-Lat., from Gk. *φῶλον*, tribe). A term given by Haeckel to the primary divisions of the animal and vegetable kingdoms, which has now generally superseded the old terms 'sub-kingdom,' 'branch,' and 'type.' A phylum is a primary group either of animals or plants, all the members of which are supposed to be blood relations descended from one and the same stem, or ancestral, primitive form. The members inherit a mode of development, larval or nepionic stages of post-embryonic development, and adult structures which taken together make them to differ from those of other phyla. See CLASSIFICATION OF ANIMALS; PHYLOGENY.

PHYSA (Neo-Lat., from Gk. *φύσα*, pair of bellows, breath, bubble). A small pond-snail abounding in quiet fresh waters throughout the warmer parts of the world. It is closely allied to the *Limnaea*, but the whorls of the amber-

PHYSA.

colored shell revolve from right to left, instead of from left to right as is the rule among spiral shells. A very wide-spread species in the United States is *Physa heterostropha*.

PHYSA'LIA. See PORTUGUESE MAN-OF-WAR.

PHYS'ALIS (Neo-Lat., from Gk. *φυσάλλης*, *physallis*, plant with husks like bladders, bladder, from *φυσᾶν*, *physan*, to blow, from *φύσα*, *physa*, bellows, breath, bubble). A genus of annual and perennial herbs and shrubs of the natural order Solanaceae, remarkable for the calyx, which becomes large and inflated after flowering is over, and incloses the ripened berry. The species are natives of temperate and warm climates, and widely scattered over the world. The common winter cherry (*Physalis Alkekengi*) is a peren-

WINTER CHERRY (*Physalis Alkekengi*).

nial, native of Southern Europe and a great part of Asia, growing in vineyards and bushy places. The berries, which have a sweetish subacid taste, are often eaten. Among the American species, perhaps the following are best known: The downy winter or ground cherry or *Physalis pubescens*, *Physalis Peruviana*, *Physalis Philadelphiaica*, *Physalis angulata*. Some of these are cultivated in gardens to a small extent. Their fruits make good preserves.

PHYSICAL FORCE PARTY. In British politics, the term frequently applied to the party of Young Ireland which advocated physical force to procure the repeal of the union with Great Britain, after O'Connell in 1843 had countermanded the Clontarf meeting which had already been proclaimed by the military authorities, and on his arrest a week later had issued a manifesto advising the people not "to be tempted to break the peace, but to act peaceably, quietly, and legally."

PHYSICAL GEOGRAPHY. See GEOGRAPHY; PHYSIOGRAPHY.

PHYSICAL OPTICS. See LIGHT.

PHYSICAL SOCIETY, AMERICAN. A learned society organized for the advancement and diffusion of the knowledge of physics. It is one of the affiliated societies meeting with the American Association for the Advancement of Science. It also holds four meetings a year for the reading and discussion of papers upon the subject of physics.

PHYSICAL SOCIETY OF EDINBURGH, ROYAL. A learned organization of Scotland instituted in 1771 and incorporated by royal charter in 1788. Its object is the advancement of physical and natural science, including anthropology, paleontology, and meteorology. Discussions take place at monthly meetings held in the Philosophical Institution, Edinburgh, where the society possesses a large and valuable reference library. The membership is divided into three classes, ordinary fellows, corresponding fellows or non-resident members, and honorary fellows, the number of the last named being limited to fifteen. For over a century the society did not print its transactions, but now publishes an annual volume of *Proceedings*, 16 volumes being issued before 1903.

PHYSICAL SOCIETY OF LONDON, THE. A learned society founded in 1874, with its office and reference library in the Physical Laboratory of the South Kensington Museum, which has since transferred its official headquarters to Burlington House, London. Its object is to promote the advancement and diffusion of a knowledge of physics, and for that purpose to have papers read, new apparatus shown, and experiments tried at its meetings, which it holds fortnightly. The society publishes *Proceedings*, which are issued quarterly, and contain the more important papers read at the meetings, as well as the official records of the society.

PHYSICAL TRAINING (ML. *physicalis*, from Lat. *physicus*, from Gk. *φυσικός*, *physikos*, relating to nature, from *φύσις*, *physis*, nature, from *φύω*, *phycin*, to produce; connected with Lat. *fin*. I was, Skt. *bhā*, to become, OHG., Ger. *bin*, AS. *bēo*, I am, Eng. *be*). A term in its largest sense including (1) the training of muscles of the body for the acquiring as well as the preservation of health; (2) the employment of the mind as a relaxation from work; (3) the physical exercise of the body as a whole as a means to health and happiness. This does not include training aimed at the enlargement of the muscles alone, which often results in ill health, since most great athletes use up their vitality early in life and die in middle age; nor does it include, except indirectly, the cultivation of certain inherited weak parts of the body, since here again

direct medical advice is the only safe plan to follow.

First of all, certain laws may be laid down.

(1) The best exercise is always attained by playing a physical game, as contrasted with gymnasium apparatus, since the game not only stimulates all the functions of the body which otherwise are checked by the sedentary life of most human beings, but it also occupies the mind and thoughts, which, being thus turned away from the cares of life, are restored and refreshed. (2) Such games and exercise should be practiced in the open air, as contrasted with the same practiced within doors, since the air of outdoors is fresher, more stimulating, freer from dust and all substances which, taken into the lungs, do harm. (3) Such exercise should take place in the daytime, as contrasted with the night, since again sunlight has direct physical benefits that are lost when the sun has set. (4) Such exercise should be taken regularly at the same time every day, since a little regular work once a day is better than a large amount once a week, or irregularly.

A game played regularly out of doors in the daytime is therefore the ideal form of physical culture. Yet for a thousand reasons this best form may be impossible. Next best is a game outdoors at night, and after this a game indoors in the daytime. Again, if games are impossible, there are many forms of exercise which can be carried on in the daytime out of doors, and those should be chosen which require the greatest mental attention, in order to still rest the mind as much as possible. Next in order would come physical exercise, exclusive of games indoors, and in the daytime, and finally, least important of all, but still infinitely better than nothing, certain physical exercises indoors during the night time. It is manifest at the start that the great body of humanity is confined to this last, but properly carried out it is itself sufficient to preserve health and often to bring back health to those who have lost it.

OUTDOOR EXERCISE.

GAMES. The best exercise in the world is unquestionably obtained in the game of polo. The entire body is at work all the time; every muscle, every nerve, is used constantly; no part of the body is neglected. In addition to this no man can play the game and keep his mind on business; for not only must all the brain he has be devoted constantly to the play, but he has under him another personality—the pony—which requires constant watching and direction. When the game is over the physical body is thoroughly exercised, the mind has been employed to its unbounded relief, and the whole man, physically tired, is renovated as nothing else can renovate him. Polo, however, is very expensive and therefore confined to the few. Next in order of importance would come the game of football, which covers all that has been said of polo, except that there is no other intelligence than that of the individual himself to guide. As in polo, football exercises all parts of the body, occupies the mind, with its absorbing interest in organization, combination—team play as it is called—and with the constant attention required to develop the best results for the individual himself. Again, this game is limited to young men, both because of the time required to practice, and because middle

age too often makes the human machine incapable of enduring the physical strain.

Lacrosse comes next in importance. It has many of the good qualities of the two first-mentioned games, and it certainly occupies the mind. But a moment's reflection will show that in lacrosse the legs and leg muscles are developed at the expense of the chest, back, and some abdominal muscles. Lacrosse, however, is also confined to young men as a rule. Lawn tennis is more available for the average man; it has the advantage of being open to women and requires less training, less preparation, fewer players, and a shorter time each day. The expense is much less and its availability is therefore much greater. Again, however, one side of the body is exercised and therefore developed at the expense of the other, which is a serious objection, and also an element is wanting that plays an important part in the games already mentioned. In polo, football, lacrosse, and such games the element of personal contact is a most beneficial factor, even though it adds materially to the danger of the games. When injuries occur they are to be deplored, but they do not destroy the good there is in the games, and the moment the personal contact feature disappears, just so soon does the individual lose all the training in self-reliance, self-control, dignity, forbearance, and courage, which are as important in physical culture as are digestion, good circulation, and normal muscles. The loss of these in such games as lawn tennis is a serious drawback, and yet, following the principles already laid down, lawn tennis is infinitely better than nothing. The game can be played almost three-quarters of the year in the northern half of the United States and all the year round in the southern half. Baseball, considered from the point of view of physical culture, is not equal to any of the games already mentioned. It is first irregular in its muscular development; then, the very nature of the game requires sudden unnatural spurts of exercise with many periods of nerve-straining delays interspersed. Golf is now thoroughly established in this country, and becomes much more available as a means of physical training than any of the games so far mentioned because it is possible and feasible for many men and women. It has not the physical culture that other games have, because it involves no personal contact and because it is slight in its development of muscular tissue. And yet for the present purpose it is very valuable, since men and women of all ages from childhood to old age can play it, and it is available nearly the entire year over the whole of this country. Furthermore, if played regularly, it furnishes a training to the man who could not stand the more vigorous demands of other games.

Ice sports may be compared in merit with lacrosse. They offer the invaluable quality of being available at a time when most outdoor games are impossible on account of weather conditions, and as such they are the winter equivalent of other sports. The open air, the stimulant to circulation, the optimism engendered by the bracing qualities of the wintry out-of-doors are all valuable, but the limited time of their use confines them to the class of substitutes for other forms of physical culture.

In a general way, track sports and rowing cover the other forms of games for out-of-doors.

and both of these should come last in any physical culture category, since they have certain distinctly meretricious elements. Rowing in eight-oared shells, in four-oars, in pairs, in singles involves racing—competition—which, good in other sports, works for evil here. There can be no question that the strain of a boat race of any kind is injurious to the heart and the lungs. In contradistinction to other games, rowing is one continuous strain and effort from start to finish. There is no respite, no temporary delay where for an instant the organs of the body can snatch a little rest. And the same is in a measure true of running of all kinds, while the added disadvantages present in all track sports is manifest in the absence of any personal contact.

Walking, much abused as it is, will do much for health if properly conducted. But walking, as here considered, is different from the employment of 'shank's mare' to conduct a body from one point to another. In the first place, the walk should be taken at the same time each day. The individual should dress for it in light, loose clothing to give the freest possible play to all the muscles. The head should be held up, shoulders well back, chest thrust far forward, and the arms bent a little, while the hands grasp two banana-shaped pieces of cork like the handles of a bicycle. The stride must be long and swinging, starting from the shoulders and including the hips, so that the whole body swings forward on one side and then on the other as each step is taken, and the side and abdominal muscles are kept constantly at work. The pace should be fast and there should always be a definite point to be reached at a definite time. One would say that any human being, no matter how busy he might be, could find time for a half hour's walk during the day or night, and if he would prepare for it in suitable clothing and follow it out as an exercise, and not as a dilatory way of getting an opportunity to think over some problem of business, he would receive material benefit thereby. Its great disadvantage, however, is that even carrying out the stride, the position of the body and the regularity of the exercise, he still secures no rest for his mind, since the mere physical act of walking does not necessarily require constant mental attention. It only requires a problem of life that is sufficiently absorbing to divert the thoughts from surrounding objects or from attention to the operation of walking to the problem itself. In fact, walking often helps the mind to work. Riding has this advantage over walking, that it does give the mind relaxation, since the management of the horse requires a certain amount of attention. But, again, riding has not the amount of physical exercise in it that walking has when the latter is properly carried out, and riding is not as easily undertaken in view of the expense of keeping a horse. In the order of importance as regular outdoor forms of special development exercise come swimming, bicycling, running, shot-putting, hammer-throwing, and so on. They are all good—that is, better than nothing, better than the same things indoors—when properly and regularly carried out; but they all have distinct disadvantages. For example, bicycling develops the legs without doing much for arms or shoulders, and the bicyclist too often leans heavily upon the handle-bars, bending far forward, compressing his lungs, training his shoulders to become 'round,' and forgetting entirely the ab-

dominal muscles that need the regular gentle development of constant movement. Swimming, which is very general in its all-round use of the body, has its distinct advantages. But it can only be undertaken at limited times in the year, and then only by him who lives near the sea or some large body of water. It is questionable for the individual, since there are many people whose circulation is far from being benefited by bathing in the constant manner which is necessary if any physical good is to come of swimming as a regular exercise.

INDOOR EXERCISE.

Sparring is perhaps the best of indoor games. It is a most admirable exercise. It uses all the muscles of all parts of the body. The swaying of the trunk, the quick movements required in all the leg muscles, the extraordinary variety of movements about the arms, neck, back, and head, all keep the muscles in good condition and stimulate circulation, respiration, and good digestion. But in addition to this it can be seen that no one who is boxing can give much thought or attention to his business, or to anything but the game in hand. It needs only a straight blow on the nose to wake up the delinquent and make him give his undivided attention to the matter in hand. Here is a game that in many ways surpasses bicycling as a means to physical culture, while bicycling, on the other hand, has the one advantage of taking the individual out of doors. Wrestling has many of the good points of sparring and as such is a good form of physical culture. Yet here the teacher is more necessary than in most games. The danger of straining muscles and weakening tendons is very great, since a contest is of course necessary, and the desire for victory prevents one or the other of the combatants from giving up when a strain becomes the penalty for not doing so. Yet both these games develop all parts of the body equally and thoroughly.

Rackets, court tennis, and handball are all capital indoor games. They employ the mind and can be undertaken for half an hour a day regularly at a certain time. The disadvantage in them over such exercises as sparring is that they develop one side of the body to the detriment of the other. A right-handed player, for example, is constantly using his right arm with the racket, and thus develops his whole right side without bringing the left side into play to any great extent. Naturally the circulation, the respiration, and the general relaxation of both mind and body go on, but the muscular development needs some specific exercise for the left side after the game is over, if the normal of physical culture is to be attained.

Fencing also has the same one-sided development, yet it adds the ease and grace of movement which make it one of the most valuable means of physical culture for women that can be used under cover of a roof. Like single stick and the many forms of offense and defense with a weapon, it really has qualities that few games can boast. The agility, quickness, grace, and *finesse* that are required have to do with physical culture in its highest sense.

SPECIAL DEVELOPMENT EXERCISES.

To go thoroughly into this large branch of physical culture would be impossible here. It is possible, however, to suggest lines of work. The pulley-weights and dumb-bells are so monoto-

nous that they do not occupy the mind, and they therefore lose a part of their force as means toward physical culture. The punching bag, on the other hand, is really a game which is played with an inanimate but very vigorous adversary. Again, however, it is necessary to add, in order to preserve a proper sense of proportion, that this is not equal to a game out of doors in the daytime and never will be; but then, on the other hand, it is so much better than nothing that it often means in so many words the difference between health and sickness. In like manner might be catalogued the apparatus of the gymnasium in the order of their desirability, such as rowing machines, parallel bars, pulley-weights, and so on. They all have their uses; they can all be set up in any private house, and they are all of service in maintaining health when nothing better can be had. Their use is precisely and only this: Exercise must be taken regularly every day in some form to stimulate circulation and respiration; exercise must be given the mind along other lines than those followed in daily life. Either the home or the club gymnasium will be better than nothing, as a little regular exercise day by day of whatever kind is better than none at all. One other method offers itself for general consideration and that, too, is better than nothing. Yet it requires what is found only here and there in mankind—the capacity for absolute regularity day by day, every day of every year. There seems to be something in the human make-up that militates against regularity, and in the least beneficial and yet easiest of forms of physical culture regularity is the whole story. Forms of exercise without the use of apparatus are best suggested by the United States Army *setting-up exercises*. They include the *Swedish system*, the *Delsarte system*, and all the other innumerable forms of setting-up exercises which have been invented. In considering these, two very different points of view must be considered. (1) If a portion of the body is weaker than all other portions—for example, if a broken leg, now healed, needs special attention to bring the long unused muscles up to standard—these forms of exercise ought to be taken under the advice of a physical culture instructor, since a thorough knowledge of anatomy is needed to point out just what exercises are most efficacious. (2) If the maintenance of general health is desired, then no teacher or instructor is at all necessary. It only needs to consider the muscles of the body. For example, before bathing, lie on the floor on your back and (1) rise to a sitting position twenty times; (2) raise the legs to a perpendicular position twenty times; (3) turn over, and, touching only the toes and hands to the floor, thrust the body upward by straightening the arms twenty times; (4) stand up, and, keeping the legs straight, bend forward and touch the finger-tips to the floor twenty times; (5) rise on the toes twenty times; (6) keeping the body straight and upright, bend the knees and sink down toward the floor twenty times, rising again by straightening the legs; (7) take hold with one hand of the end of a door and grasp with the other the door frame when the door itself has been opened about one-quarter of a quadrant; standing thus, allow the body to fall forward so that the chest passes through the opening and the shoulders are thrust far back until the shoulder-blades touch; do this

twenty times; (8) place the hands on the hips, stand straight, and then bend forward as far as possible twenty times, backward twenty times, to the right side twenty times, to the left twenty times; (9) standing straight, go through—twenty times each—the motions of raising the arms at full length above the head, backward, forward, and down. When a child or youth or a young girl is in question the advice of an expert is, of course, almost necessary.

GENERAL CONSIDERATIONS.

In conclusion it is necessary to suggest a few general rules which apply to all forms of exercise for physical training. Food is the principle question. Eat three times a day and always at the same hours. Eat simple meats and vegetables, a light breakfast, a moderately light lunch or mid-day meal, and a moderately heavy evening meal. Never eat at any other time. By simple foods is meant meat and vegetables cooked simply without sauces and extra substances which only confuse the digestive organs when they begin their wonderful work of turning food into blood and tissue. Drink plenty of water between meals, but little or none at meals. Drink alcoholic drinks or not as you like, or as your belief dictates; but remember that temperance is neither too much nor too little, and the actual amount per day which is really temperate must in each case be decided by the individual. There have been men who drank temperately all their lives and lived to be ninety and the quantity per day which they consumed would have killed another man in a year. Temperance is the only rule, and as what is temperate for one is intemperate for another, each must decide for himself. Clothing has much to do with physical culture. In parts of the United States the climatic changes are great, but it should be remembered that our houses are of about the same temperature all the year round. Therefore the underclothing should be of the same thickness all the year round and the outer clothing should fit the outer climate of the day. But more important perhaps than this is the rule that underclothes should be changed once every day. After the regular occupation of the day, just before dinner or supper, say at six or seven o'clock, every man and woman should put on a clean set of underclothing. The physical benefit is immense, but it does not compare with the mental rest and recreation that will result from this simple aid of physical culture. Bathing is another necessity. Each man and woman immediately after rising and taking fifteen minutes of exercise, should take a shower bath of first warm and then cold water, or if a shower is impossible, an ordinary bath in a tub. Never neglect the final cold water. It closes the pores of the skin and avoids the danger of taking cold. The feet are perhaps as important as anything. Napoleon said that an army with good shoes could do anything he asked of it. So might a man say that his body will do anything he asks of it if his feet are well cared for. Buy good shoes, and take care that they are not too large, and are well made. Keep them carefully and change them at least once a day in the early evening. Have several pairs so that the shoes can have a rest every other day. Finally *regularity* in sleeping, eating, dressing, and exercising is the important detail. Such are the extraordinary powers of the human body that it responds to regularity, to habit, as to nothing else. It be-

comes accustomed to certain things at certain times and it will serve you better than you serve it, if you will but treat it temperately, regularly, and generously. If you sleep regularly, eat regularly, dress regularly, exercise regularly, you can put your physical and mental body to such strain in the way of work as would kill the irregular man in a few months—and that is after all the substance of all physical culture.

PHYSICIAN (OF. *physicien*, *fisicien*, from Lat. *physicus*, from Gk. *φυσικός*, *physikos*, natural philosopher, physician, from *φύσις*, *physis*, nature, from *φύειν*, *phyein*, to produce). In law, one who has complied with all State regulations in regard to the study of medicine, and who may lawfully practice medicine. Most States require a medical student to pass a State examination satisfactorily, and thereupon grant a license to practice to successful candidates. Such provisions are constitutional. A person who holds himself out as a physician is considered to represent that he has the ordinary skill of one of his profession. Lack of skill or negligence on the part of a physician, resulting in injury to a patient, are called malpractice (q.v.). It is generally held to be optional with a physician as to whether or not he will attend a person calling him.

The relation of a physician and patient is a confidential one, and the former is bound not to divulge any of the secrets confided to him by the patient, even on the witness stand. The statutes of each State in regard to the practice of medicine should be consulted. See MALPRACTICE; EVIDENCE.

PHYSICK, fiz'ik. PHILIP SYNG (1768-1837). An American physician, born in Philadelphia, educated at the Friends' Academy. In 1788 he went to Europe, studied with John Hunter, and was admitted to Saint George's Hospital in 1790. In the same year he received a diploma from the Royal College of Surgeons, and assisted Dr. Hunter for one year. Returning to Philadelphia in 1793, he was appointed physician to the yellow-fever hospital at Bush Hill; in

1794 surgeon to the Pennsylvania Hospital; and the following year, on the recurrence of the yellow-fever epidemic, he was placed once more in charge of the Bush Hill Hospital. In 1801-16 he was surgeon to the Philadelphia Almshouse Infirmary; in 1805 professor of surgery in the University of Pennsylvania; in 1819 called to the chair of anatomy, which he filled until 1831; in 1821 consulting surgeon to the institution for the blind; in 1824 president of the Philadelphia Medical Society. In 1825 he became a member of the Royal Academy of Medicine in France, and in 1836 honorable fellow of the Royal Medical and Chirurgurgical Society of London. He was the author of *Deapoplexia* (1792).

PHYSIC-NUT (*Jatropha*). A genus of about 70 species of tropical shrubs and trees of the natural order Euphorbiaceæ, characterized by alternate, stalked, angled, or lobed leaves, corymbs of flowers on long stalks, and the acrid oil of their seeds. The common physic-nut (*Jatropha Curcas*) of the East Indies, introduced into the West Indies, southern Florida, and other warm parts of the world, is a small, much branched, rapidly growing tree or bush with a milky juice. It is used for fences in many tropical countries. The expressed oil, commonly called jatropa oil, is used for illuminating purposes, and has been used in medicine. The French or Spanish physic-nut (*Jatropha multifida*), an American shrub with many-lobed leaves, yields an acrid oil, called oil of pinhoen. To this

PHYSIC-NUT.

genus belongs the pinocillo (*Jatropha lobata*) of Peru, the roasted seed of which is an agreeably flavored food. Incisions in the stem of this tree allow the escape of a clear bright powerfully caustic liquid which after some time becomes black and horny, but retains this property for years. Physic-nettle (*Jatropha urens*), a native of the Southern United States, has similar qualities.

PHYSICS (from Gk. *φυσικά*, *physika*, nom. pl. neu. of *φυσικός*, *physikos*, relating to nature). Physics is one of the successors of the study formerly called natural philosophy, or the science of the phenomena of nature as revealed to us by our senses and as interpreted and systematized

by our intellects. The name itself is the plural of the word 'physic,' which was used as early as the fourteenth century to mean natural philosophy, but which afterwards became restricted to mean the science of medicine, and finally to mean a medicine or drug itself. While physics in its modern sense comes closely in contact with chemistry, astronomy, and many other sciences, it is impossible to state in words its exact scope. It may be said,—however, in general that the study of physics includes the phenomena of acoustics, of heat, of light, of electricity and magnetism, and of mechanics to a certain extent. Within recent years many subdivisions have been made both in physics as a general study and also in its various parts. The subjects pertaining to the nature of solutions are now included in physical chemistry; the spectroscopic examination of the sun, stars, etc., together with the related theories, forms the science of astrophysics; the observations and theories of earthquakes, heat conduction on a large scale, volcanoes, etc., are now studied under the name of geological physics. Practical applications have been made of many observations in physics, and there are schools of engineering devoted to the study of these matters. Among the branches of engineering are mechanical, hydraulic, steam, and electrical.

The fundamental idea of physics is that we learn by means of our senses certain facts in regard to natural phenomena, which are independent of time and space. These last two concepts, namely those of time and space, are considered as intuitive. The name matter is given provisionally to whatever is the cause of our sensations; but it is *defined*, naturally, in terms of its properties. There is not necessarily involved any assumption as to the reality of matter; rather, there are found certain mathematical expressions, certain differential equations, which express our knowledge of nature, but which we interpret in such language and with such ideas as correspond to our mental pictures. Associated with this idea there are two great divisions of physical methods; one may be called the laboratory method, the other the method of mathematical physics. (See LABORATORY.) The laboratory method consists, first, in making a series of observations and amassing information in regard to phenomena, but further in seeking to obtain a generalization with which the observed phenomena may be in accord. The object and scope of mathematical physics is well expressed by Professor Poincaré in his introduction to the *Reports of the International Congress of Physics* (Paris, 1900). The fundamental method is to devise certain postulates and to state such axioms as will lead by rigid mathematical processes to formulæ which may be compared with observed phenomena. Thus by means of the methods of logic conclusions may be drawn connecting many phenomena which on their face are unrelated.

HISTORY OF PHYSICS. It is remarkable to note how few facts other than obvious ones were known to the ancients in regard to nature, and also to find how few instruments were available for what may be called scientific observation. Beyond a doubt simple forms of instruments were known for the measurement of time, such as water-clocks, sun-dials, etc., and the Chinese at least had a knowledge of some of the simple

properties of a magnet. The law of the reflection of light was generally known and lenses were in use for various purposes. The law of the lever was known to Archimedes, as were also certain of the laws of hydrostatics. There was a knowledge of harmony in music more or less incomplete. A few observations are also noted in regard to electric attraction and the facts of meteorology.

Up to the Middle Ages there are few if any facts to be recorded in regard to the growth of natural philosophy, because the Romans were content with the knowledge left them by the Greeks, and the intellectual activity of the Arabs seemed to be concentrated, as far as physics is concerned, in the person of Al-Hazen, who was interested largely in optics. There was a revival of interest in nature during the thirteenth century, as shown by the work of Roger Bacon and Peregrinus. In the sixteenth century Copernicus lived, and he was followed by Galileo, Kepler, Stevin, Gilbert, and others.

The effect of the life and work of Galileo in Italy and of Gilbert in England cannot be overestimated. There was a universal revival of intellectual activity and a universal interest in the study of natural phenomena. Each of these two men emphasized the need of experimental study and the utility of logic apart from observation. Galileo's greatest contribution to physics was the statement of the principles of mechanics. He was succeeded by pupils whose interest and influence was so great that they led to the establishment of academies and learned societies throughout Europe. With the appearance, however, of Huygens's *Horologium Oscillatorium* (1673) and Newton's *Principia* (1687) physics came to the front as the most important of the sciences. The methods used by these two men, both in their observations and in their statement of laws of nature, have served as the models for succeeding generations. They were followed by two schools, one interested in the mathematical development of mechanics, the other interested in the purely experimental side of the subject, whose legitimate predecessors were Torricelli, Pascal, Boyle, and Guericke.

MODERN TIMES. The development of our present knowledge of physics is more fully described under the separate headings of its various subjects; namely, acoustics, heat, light, electricity, and magnetism. It should be sufficient in this place to refer to a few names in connection with each of the subjects. Our accepted ideas in regard to the nature of heat and heat effects are due to the researches and theories of Black, Rumford, Davy, Carnot, Clausius, and Joule. In light we owe most to Young, Fresnel, Fraunhofer, Kirchhoff, and Stokes. In the subjects of electricity and magnetism a long list of names should be mentioned, but among these those of Volta, Cavendish, Ampère, Oersted, Faraday, Henry, Gauss, Weber, Maxwell, and Hertz are easily the most notable. To Helmholtz alone, it is only fair to say, all of our accepted ideas of the theory of sound are due. The names of no living men have been included in the above summary, but any such list would be incomplete without the addition of the names of Kelvin, Rayleigh, Lorenz, J. J. Thomson, and Röntgen, who have contributed so much to the most recent ideas in regard to the fundamental concepts of nature.

Previous to the nineteenth century there were

three great principles of physics which were firmly established and which deserve to be called laws of nature. These were the law of gravitation, the principle of the conservation of matter, and that of the conservation of momentum. Some doubts have recently arisen as to whether the weight of a definite quantity of matter remains unchanged as its state is altered, but there seems to be no reason for doubting the principle of the conservation of matter itself. The most notable fact in the history of physics during the nineteenth century was the development of the principle of the conservation of energy and its application to all fields of science. This great development was due largely to the efforts of J. R. Mayer, Helmholtz, and Joule. Other great principles, such as the second law of thermodynamics, were expressed in words, and will be found discussed in other places. The kinetic theory of matter was also elaborated and established on a firm basis.

Beginning with the discovery of the X rays by Röntgen in 1895 and of the radiation from uranium by H. Becquerel in 1896, there has been a progress in physics and in our knowledge of the properties of matter which has been one of the most striking facts in the whole history of science. The point of departure in our new knowledge comes from the epoch-making discovery by J. J. Thomson that in their passage through air both the X rays and those from uranium make the air a conductor for electric currents. This discovery led at once to investigations by observers the world over in regard to the nature of the ionization of air and of the radiations which produce it. It was soon found that many substances other than uranium had this same power of emitting radiations which would ionize a gas; such were thorium, and the newly discovered elements, radium and polonium. These substances are said to be 'radio-active;' and it was observed that nearly every body in nature was 'active' to a greater or less degree. The properties of the radiations themselves were carefully studied and analyzed, and their properties other than that of ionization were investigated. There are always present in the radiations from such bodies both positively and negatively charged particles of matter whose velocities vary within wide limits. When the velocities of the negatively charged particles as produced in various ways were studied, a most remarkable fact was observed. Attention had been called many years ago by J. J. Thomson to the fact that if a charged sphere were moving rapidly it would have an effective inertia greater than that which would be observed in case it were uncharged. In other words, an electrical charge in motion has an apparent mass quite apart from that of the matter carrying it; and formulas have been deduced by Thomson, Heaviside, and Abraham connecting this mass of the charge with the quantity of charge, its velocity, and its acceleration. It was observed in the case of the negatively charged radiations above referred to that their apparent mass was exactly that which would be calculated from the formulæ on the assumption that the mass was due entirely to the moving charge. This discovery renewed at once the theories of matter which had been advanced before, in accordance with which the inertia of matter is a property due to the motion of an electric charge. The name 'electron' has

been given these charges when considered apart from matter, and a most interesting discussion of their properties and of the theories of matter based upon these is given in a series of papers by Sir Oliver Lodge in the *Electrician* (London) during the winter of 1902-03.

One of the great contributions of the nineteenth century to physics was the development of the idea of the luminiferous ether. The necessity of a medium for the transmission of the waves which produce the sensation of light had been recognized for many years and was clearly stated by Fresnel and others. Faraday had also come to the conclusion that a medium was necessary for the transmission, or rather existence, of electric and magnetic forces, and had suggested that possibly this medium might be identical with the one that carried 'light waves.' Maxwell showed by theoretical considerations that the velocity with which an electromagnetic disturbance would be propagated in the medium referred to by Faraday must be numerically equal to the so-called 'ratio of the electrical units,' and further showed from experimental evidence that this was equal to the number expressing the velocity of light. He also proved by a mathematical investigation that the electromagnetic waves were identical in all respects with those with which we are familiar in the phenomena of light, and thus established the fact that only one medium is necessary for the explanation of the phenomena of light, electricity, and magnetism. The connection between this ether and ordinary matter has been investigated by many observers, as described in the article on ABERRATION. The accepted theory at the present time is that the ether does not move as material bodies are carried through it; and this, in connection with the ideas of electrons, has been elaborated by Lorentz into a theory which is able to explain in the most satisfactory manner the phenomena of dispersion, metallic reflection, and stellar aberration. There are many difficulties, however, which still remain to be investigated in regard to the properties of the ether, in spite of the great progress marking the beginning of the twentieth century. If the inertia of matter is to be regarded as capable of explanation, as indicated above, from the standpoint of electricity, there still remain two great problems for solution. What is the nature of an electric charge? and what is the cause of gravitation? The development of physics at the present time is tending toward investigations of these two questions.

PHYSIOCRATS (from Gk. φύσις, *physis*, nature + κρατείν, *kratein*, to rule). A French school of political and economic philosophers, known to their own generation as *Les Economistes*, who wrote against the antiquated methods of the State in encouraging industry (see COLBERT), and in favor of agriculture, industrial freedom and natural liberty. The school flourished from 1756 to 1776. The founder and leader of the school was François Quesnay (q.v.), a noted surgeon, metaphysician, and, after 1749, physician to Madame de Pompadour. With Quesnay is often associated in the founding of the sect the name of Jacques Claude Marie Vincent de Gournay (q.v.), who did not, however, endorse the extreme views of the school respecting the paramount economic importance of agriculture. The most earnest disciples and indefatigable propagators of the Physiocratic doctrine were the elder Mirabeau, Mercier de la Rivière (1720-94), and Dupont de Nemours (q.v.), editor of the works of Quesnay and Turgot and of the Physiocratic journals. Among the statesmen, rulers, and princes of the time who accepted the main doctrines of the Physiocrats were first and most important, Turgot (q.v.), Minister of Finance under Louis XVI.; Charles Frederick, Margrave of Baden; Gustavus III. of Sweden; Leopold II., Grand Duke of Tuscany, and afterwards German Emperor; Stanislas of Poland; the Emperor Joseph II.; and Charles III. of Spain. With some of them the acceptance was little more than half-hearted, and the only monarch who made an earnest attempt to carry out their programme of reform was Charles Frederick of Baden. He tried to apply their principles in three villages, but finally abandoned the attempt.

The general doctrine of the Physiocrats was an extension to the economic sphere of the theory of natural liberty which Locke, Hutcheson, Shaftesbury, and others had applied to the sphere of politics and religion; but, unlike the British philosophers, the Physiocrats denied that the natural rights of the individual could be abridged by any social contract. Every man, they held, has a right to the free exercise of his faculties, so long as he does not infringe the like liberty of others, and this involves the further right to the undisturbed enjoyment of the property which results from the exercise of his faculties in productive labor. It follows from these rights that the sole function of government is to protect life and property and to administer justice, and no interference by the government with commerce and industry is permissible—in the classic phrase of the school, *laissez faire, laissez passer* (q.v.)—but within the restricted sphere noted above the Physiocrats advocated a strong monarchical government, a “legal despotism, tempered only by an enlightened public opinion.”

The peculiar economic views of the Physiocrats seem to rest upon a confusion of wealth with material objects, leading to the conclusions that agriculture alone yields a surplus product—*produit net*—above the expenses of production; while manufactures and commerce, which merely

change the form or position of raw materials, are barren. As agriculture is the only form of production yielding a value in excess of the cost of production, they advocated that taxes should be levied upon rent—which expresses or measures the ‘net product’—so as to avoid the expense and friction attendant upon the shifting of the tax to this source when placed originally upon other objects. They thus gave to political economy the fruitful theories of surplus value and the single tax—*impôt unique*. (See POLITICAL ECONOMY.) The scientific virtues and defects of the Physiocrats may be traced to one and the same cause, the belief in a beneficent and absolute natural law governing the moral and social universe with the same rigidity and precision as the material universe is governed by physical law. This belief made them at once narrow but precise, systematic but unmindful of the difference between physical and psychical phenomena, careful in definition, distinction, and classification, but careless of the effects of customs, law, and the diversity of human motives. They have exercised a deep and lasting influence upon political economy, and it is now usually admitted that Quesnay, rather than Adam Smith, is to be regarded as the ‘father of political economy.’ Opinions differ regarding their influence upon the practical affairs of the day. They undoubtedly stimulated the study of agriculture, suggested several important agricultural improvements, called attention to the oppression of the peasantry and elevated their importance in the eyes of the nation, and secured a freer intercourse of trade—particularly in breadstuffs—within the French kingdom. In the early years of the French Revolution their doctrines exercised an appreciable effect upon the Constituent Assembly, but their most striking practical influence was exercised through Turgot (q.v.), who, while not a professed Physiocrat, made many earnest attempts, both as intendant of Limoges (1761-74) and as Comptroller-General of Finance (1774-76), to abolish the *corvées* and the guilds, to introduce free trade in corn, to reduce taxation, and to accomplish the general reforms which the Physiocrats demanded.

Among the most important publications of the Physiocrats are Quesnay’s articles on *Fermiers* and *Grains*, published in the *Encyclopédie* of Diderot and D’Alembert; *Le droit naturel*, published with other of his writings in the *Physiocratie* (which gave the school its name), edited by Dupont de Nemours, and his *Tableau économique*, 1758, “the Bible of the Physiocrats,” reprinted for the British Economic Association, London, 1894; Mirabeau’s *Théorie de l’impôt*, 1760, and *Philosophie rurale*, 1763; Dupont de Nemours’ *De l’origine et de progrès d’une science nouvelle*, 1767, published in his *Physiocratie*; Mercier de la Rivière’s *L’Order naturel et essentiel des sociétés politiques*, 1767; and Turgot’s *Réflexions sur la formation et la distribution des richesses*, 1770.

BIBLIOGRAPHY. Oncken, *Euvres de Quesnay* (Frankfort, 1888); Hasbach, *Die allgemeinen philosophischen Grundlagen der von François Quesnay und Adam Smith begründeten politischen Oekonomie* (Leipzig, 1890); Higgs, *The Physiocrats* (London, 1897).

PHYSIOGNOMY (OF. *physiognomic*, *phisionomic*, Fr. *physionomic*, from Gk. φυσιογνωμία,

physiognōmia, φνσιωγνωμία, *physiognōmonia*, art of judging by the features, from φνσιωγνώμων, *physiognōmōn*, one who judges by the features, from φύσις, *physis*, nature + γνώμων, *gnōmōn*, judge, from γινώσκω, *ginōskō*, to know; ultimately connected with Eng. *know*). In general, the form and expression of the visage or face, especially when regarded as indicative of character; specifically, an art or system of reading character from the face. This system was framed by Lavater, and is related to that of phrenology as formulated by Gall and Spurzheim; it was extended and expanded in America chiefly by S. R. Wells in connection with O. S. Fowler, L. N. Fowler, and others. In its application the system involved temperament as determined from complexion, etc.; the general aspect of head and face, sometimes in comparison with those of animals whose traits the individuals were considered to imitate; the form, size, and prominence of particular features, etc. The chief bases of the system were assumed (1) localizations of functions in the brain, and (2) corresponding localizations in the external features. Later researches in cerebral and general anatomy and physiology have failed to establish most of the assumed localizations and correspondences, while modern students commonly regard facial forms and features rather as hereditary ethnic characters than indices of individual disposition; so that the current art may be defined as character-reading from facial expression. A good many modern students, among whom Cesare Lombroso may be regarded as the leader, distinguish between normal and abnormal types of physiognomy, and view the latter as indices of either degeneracy or reversion to lower ancestral types; and some writers have sought to combine certain classes of abnormalities in a 'criminal type' for the guidance of students, jurists, and statesmen. The recognized abnormalities include certain malformations of face and head, asymmetry of features sometimes analogous to that accompanying epilepsy or paralysis, excess or deficiency of hair and beard, unusual pigmentation, and various stigmata, either congenital or of later development. The coördination of these abnormalities with conduct forms a considerable part of the foundation for criminology (q.v.) as defined by Lombroso. The general form and expression of the visage are among the ethnic traits recognized in defining races and peoples. The facial angle, i.e. the degree of prognathism, is among the most useful measures both in comparative anatomy and in ethnology; the shape of the jaw, the conformation of the cheek-bones, the position of the ocular orbits, the number and character of the teeth, and the nature of the dermal appendages (hair, beard, brows, etc.) are also of primary importance as ethnic characters; while the superior expressiveness of the features of more advanced peoples is among the characteristics noted by the ethnologist.

PHYSIOGRAPHY (from Gk. φύσις, *physis*, nature + -γραφία, *-graphia*, description, from γράφω, *graphō*, to write). There is much difference in the usage of the term physiography. It is employed as a synonym for the older term physical geography; as a term to include a general introduction to science; for the study of the physical environment of life; and for the study of land forms alone, that is as a synonym for the

recently proposed name geomorphology. In the United States the term physiography is rapidly coming to replace the older term physical geography, at the same time that a more scientific basis is being introduced into physical geography. In this sense, physiography is concerned with the study of air, ocean, and land, with the object of understanding their present condition and influence on life. To understand present conditions leads back into meteorology, oceanography, and geology; to appreciate their influence on life presupposes knowledge of history and biology at least. It is no uncommon belief that physiography is too complex, and drawing upon too many other subjects to have distinct boundaries, and hence to deserve the name science. It is true that there is no general agreement as to the exact boundaries; but this is by no means proof that physiography can have no boundary. Some one has said that geology is a study of the past. That is to say, a geologist, to appreciate his subject fully, must have knowledge as a physiographer; and a physiographer must know the past that he may use geology as a tool in his attempt to understand the present.

ASTRONOMICAL ASPECTS. The study of physiography deals essentially with the earth—its spherical form, its envelopes of air and water, its cold crust and heated interior, and their influence on life. Yet no thorough appreciation of these conditions and influences is possible without a general knowledge of the astronomical relations of the earth. The earth as a sphere, and as a member of the solar system in which it so moves as to give day and night and the seasons, are facts of fundamental importance to an understanding of changes in the earth; and the spherical form of the earth, and the presence of heat among the members of the solar system, furnish adequate reason for a consideration of the hypotheses for the origin of the earth. This does not mean that the subject encroaches on astronomy; it is dealing with the earth, but it inquires of astronomy the reasons for terrestrial phenomena of vital importance, and applies these to an interpretation of the phenomena in their relation to life.

THE AIR. The influence of the air on life is universal. Its oxygen and carbon dioxide; the influence of its pressure; the effects of its density, for example, on the flight of birds; its water vapor; its winds and their effects—these are among the many reasons why a study of the air properly forms a part of physiography. The science of meteorology furnishes the explanations, and with these the physiographer needs to be familiar. In order that he may understand the distribution of life he should know why there is vapor, why winds blow as they do, why there are rainy and desert regions, and why there are storms. The branch of physiography that deals especially with this phase of the subject is climatology. If the climatologist studies only the causes of climate he becomes a meteorologist; but if his especial concern is the understanding of the laws of climate with reference to their influence on life, he is a physiographer. The study of the air has a bearing on other phases of physiography. Waves and ocean currents depend on air conditions, and to understand them calls for a knowledge of air movements. Rain, river floods, the difference between the topography of arid and moist lands, and the existence of glaciers, are among the fea-

tures of the land that depend upon a knowledge of the air for their proper appreciation. Each of these reacts on life. Thus, along several lines, it is evident that there is a phase of air study, calling for an appreciation of the science of meteorology, it is true, but with its main object the investigation of the influence of the air on the environment of plant, animal, and human life.

THE OCEAN. The temperature and movements of the ocean, dependent upon sun's heat and air movements; the tides, dependent on the attraction of the sun and moon; the composition of the ocean water, its depth, and the characteristics of the ocean bottom are among the important physiographic features of the ocean. Each of these has an influence on life. The ocean supplies vapor to the air; its vast expanse and its currents influence the temperature of the air and aid in those movements of the air by which the temperature and rainfall of the lands are profoundly affected. Life in the ocean as influenced by its environment; the effect of ocean influence on the life of the lands; the ocean as a barrier to the spread of life; and its importance to man in commerce and many other ways are among the subjects with which a physiographic study of the ocean is concerned. The oceans and the lands are profoundly interrelated. The waste of the land is carried to the sea by rain and rivers; and the oceanic agents are attacking the land along its border, forming many varied coast features. Changes in level of the crust lower parts of the land beneath the sea, and raise sea bottoms to form dry land. No study of the lands can promise the best results without a knowledge and appreciation of the conditions of the coast line and sea bottom. From this it is evident that the physiographic study of the ocean is broadly interrelated with the study of the land and air. The science of the study of the ocean is called oceanography; and, as in the case of meteorology, while the physiographer must understand the principles, his concern is far less with the science of oceanography than with the application of its principles to an understanding of their influence on life.

THE LANDS. There is a conflict of forces at the present time operating to modify the forms of the lands which themselves so greatly influence life. On the one hand contraction of the interior of the earth is causing changes in the level of the crust as a result of which continents are raised and ocean bottoms depressed, while mountain chains, volcanoes, plateaus, and plains are being made. On the other hand opposing forces are at work on the land removing the rocks that lie above the sea level and dragging the fragments into the sea. The weather disintegrates the rocks, the rains, rivers, and winds remove the fragments. Glaciers occasionally aid in this erosion, and the seacoast is the seat of further important work of this kind. The result of the opposing forces of elevation and destruction has been to produce a very complex land surface, and it is one of the most important provinces of physiography to understand this land surface and to point out its effect on life. For this phase of physiography the name geomorphology has been proposed. It is intimately related to geology and makes use of geological principles. It is by some considered as a branch of geology; that is, the geology of the present.

Many of the principles relating to the physiography of the lands are stated under other topics.

(See RIVER; LAKE; MOUNTAIN, etc.) In this place only the scope of the subject will be indicated. The simplest land form is the plain (q.v.), the most extensive and perfect plains being on the sea bottom. They may be classified as constructional and destructional, the former being represented by elevated sea-bottom plains, lake-bottom plains, delta plains, flood-plains, etc.; the latter by plains of marine denudation, plains caused by lateral erosion of rivers, etc. In the beginning their surfaces are level, they permit the ready spread of animals and plants, and, if the climate favors, they are usually well suited to occupation by man. If newly formed, or young, the surface may be so level that water stands on it as lakes or swamps; but with increasing age the surface is drained, streams cut valleys, the flat-topped divides are narrowed, and the lakes and swamps are destroyed. In the development of these stream valleys, if the plain stands high enough above sea level, or base level, the rapid cutting along the channels permits the development of deep, steep-sided valleys. In these young valleys the vigorously working streams flow with rapid slope, and with occasional falls where hard layers are encountered. If the land is high above base level, that is, if it is a plateau, the young streams may so trench the land that travel across country is prohibited by the deep cañons. In such cases the interstream areas only are habitable and are chosen for roads and railways. With time the valleys broaden, the slopes become more gentle, and both the valley bottoms and sides invite settlement. Such a land surface is mature, and is well illustrated by the Mississippi Valley. There are few if any falls, the rivers are navigable, and they are bordered by flood plains—waste from the land along the course which the river is unable to bear to the sea over its gentle lower slope.

The Alps as a barrier to the spread of life, and as a refuge from invasion, stand as rugged mountains reaching above the snow line. Their ruggedness is due to their youth and to the fact that denudation, working high above base level, on rocks of very different degrees of hardness, has been able to work rapidly and sear and carve the mountains profoundly. With greater age mountain peaks and ridges are lowered, the valleys are broadened, and the rivers slowly shift position, eating their way backward at the headwaters, robbing weaker opponents of drainage area, and pushing their way across ridge after ridge, as in the Appalachians. The importance of the river gaps to transportation and the influence of mountains on occupation are observable throughout the world.

Rising land gives a straight coast, as along Western South America; sinking forms an irregular coast, with many islands, peninsulas, harbors, and straits, as in the Northeastern United States. A shelving coast of soft materials which has recently assumed its position is skirted by sandbars, like the coast south of New York, while a young coast of hard rock has bold headlands, with beaches in the bays. Here again are innumerable opportunities to study land forms in order to understand their cause and point out their influence on life.

The physiography of the lands investigates islands, peninsulas, capes, plains, plateaus, and valleys; it studies their differences in form; it distinguishes between the different kinds of hills,

cliffs, talus slopes, etc. In fact, it studies all land features, and in all cases it is concerned with the form, its cause, its relation to other land forms, and its effects on life. It shows how, in their conflict, the movements of the crust and the operation of the agents of denudation make land forms by constructional and by destructional processes. It shows that there is a constant building up of land forms by both the internal forces of elevation and the external forces of denudation; and that there is constant tearing down by the forces of denudation. It is the province of physiography to trace the operation of these processes, both to see how they modify the lands and to discover the influences of these modifications on life.

PHYSIOLOGICAL SELECTION. A theoretical explanation proposed by Romanes of the evolution of species on the principle of the prevention of intercrossing. Hence Romanes also referred to the assumed law as that of the "Segregation of the fit." He was led to his generalization by consideration of the facts of sterility between species, and of fertility between varieties and races. Basing upon observation the postulate that the reproductive system was the most susceptible to change of any part of an animal's organization, he argued that in that system would often (perhaps more often than in any other) arise independent variations in individuals. If these were of such a character as to tend toward sterility between them and parent-forms, they would tend to separate the variety from the species and a new species would evolve. Romanes concluded that the principle of sterility between species was essential to the separate existence of species.

PHYSIOLOGY (Lat. *physiologia*, from Gk. *φυσιολογία*, natural philosophy, from *φυσιολόγος*, *physiologos*, discoursing on nature, natural philosopher, from *φύσις*, *physis*, nature + *λόγος*, *logos*, word, account, ratio, from *λέγειν*, *legein*, to say). Under the term physiology, when used in its widest sense, we include all that is known of the properties of living matter. Following the great line of demarcation of living things into animals and plants, we have an animal physiology and a plant physiology. The two subjects, while closely related, are sufficiently different to be considered as separate sciences and to require specialists of different training for their study. In animal physiology we have to deal especially with the properties of animal protoplasm, and although the fundamental properties of this material are believed to be much the same in all animals, yet for each animal or group of animals there are minor distinctions which are due in part to fundamental differences in structure, and in part to the variety in the physiological mechanisms developed in different animals. In what follows an attempt will be made to present briefly

an outline of the important facts and principles of human physiology, but it should be remembered that the body of facts included under this designation have been obtained in many, if not in most cases, by direct study and experiment upon lower forms of life, not only upon the mammals most closely related in structure to man, but also upon the simplest organisms which for one reason or another have offered especial opportunities for study.

It is convenient to consider the physiology of the human body under two general heads, namely, the properties of the tissues and the properties or functions of the organs and mechanisms. The human body, like that of other animals, starts as a single cell, the fertilized ovum. During the progress of development this cell multiplies to form an infinite number of cells which gradually become differentiated in structure and segregated into groups that are known as tissues. Each tissue is characterized by its appearance, as seen by the eye or with the aid of a microscope, and also by known differences in chemical composition and reaction. We distinguish in the human body the muscular tissue, the nervous tissue, the epithelial tissue, the gland or secreting tissue, the blood, the connective or supporting tissue, the lymphatic tissue, the tissue forming the red blood corpuscles, and so on. Each tissue is different not only in structure, but in its properties. Along with the differentiation in form there is a specialization in function. Without attempting to describe their microscopic characteristics, a word or two may be said of the more important physiological properties of some of these tissues.

THE MUSCULAR TISSUES. In man, as in the other vertebrates, we distinguish three kinds of muscular tissue: (1) the cross-striated or voluntary muscle which forms the musculature of the body by means of which our voluntary movements are made; (2) the heart-muscle, composing the walls of the heart; and (3) the plain or unstriated muscle which is found in the walls of the hollow viscera, such as the alimentary canal, the blood-vessels, the uterus, the bladder, etc. The common characteristic of these three tissues is the property of contracting. While this property may occur in other tissues, it reaches its greatest development in the muscles. In cross-striated muscles the contraction is always started by a stimulus received through the nerves and originated usually in the brain by an act of the will. The contraction is very rapid. A single stimulus gives a single or simple contraction that occupies less than one-tenth of a second. All of our ordinary voluntary contractions are, however, compound or tetanic, that is, they are composed of a rapid series of simple contractions fused together more or less completely. The rapid series of contractions is due to a series of stimuli or nerve impulses received from the brain through the nerve fibres connecting it with the muscle. In every voluntary movement, therefore, whether short or prolonged, we must imagine to ourselves a series of changes in the nerve cells of the brain, which are propagated along the connecting nerve fibres to the muscle or muscles and there set up a series of contractions so rapid that they become fused into a long-lasting contraction or movement.

Plain muscle is characterized by the slowness of its contractions. The tissue as found in different parts of the body varies somewhat in this respect, but in all cases its contractions are very

much slower than in the cross-stripped muscle. The plain muscle, moreover, is not under voluntary control; we are not conscious of the movements of the stomach, the blood-vessels, etc. The contractions of these organs are brought about by stimuli conveyed to the muscle through the so-called sympathetic nervous system. The slow and prolonged contractions of plain muscle explain the gentle, long-continued movements of the viscera such as occur in the action of the stomach and intestines in propelling food along their length. Heart-muscle is somewhat intermediate in structure between the plain and the cross-stripped varieties. Its contractions are also intermediate in duration, but approach closer to the quick movement of the striped muscle. The predominant characteristic of heart-muscle, however, is its property of making spontaneous rhythmic contractions which are due not to external stimuli received through the nervous system, but to processes arising within itself. To this property is due the rhythmic beat of the heart.

NERVOUS TISSUE. The nervous tissue is found in the brain, the spinal cord, the nerve ganglia of the sympathetic system, and the peripheral nerves or nerve trunks distributed throughout the body. The nerve tissue consists of nerve cells and their processes. The body of the cell lies in the nerve centres, that is, the brain, the spinal cord, and the ganglia, and the typical cell has two kinds of processes, one comparatively short and much branched, known as the dendrites or dendritic processes, the other but little branched and in some cases very long, as much as two or three feet. This latter branch is known as the axis-cylinder process; it may pass out of the nerve centres to be distributed to the other tissues forming the essential part of what we call nerve fibres. It is important, therefore, to bear in mind that nerve fibres are essentially long processes from nerve cells and form the mechanism by which the nerve centres are connected with and influence the activity of the peripheral tissues. Physiologically, the important function of a nerve fibre is to conduct a change or process known as the nerve impulse. This impulse travels along the fibre at a rate of about one hundred feet per second. The nerve fibres fall into two great groups, those that convey impulses from the peripheral tissues to the nerve centres, and those that convey impulses from the centres toward the periphery. The former group compose the afferent or sensory fibres, the latter name being used because in many cases the impulses finally reach the brain and give rise to conscious sensations of various kinds. In many cases, however, the impulses conveyed to the nerve centres by the afferent fibres cause no change in consciousness, but manifest themselves by what we call reflex effects, as, for instance, in the movements of the intestines, the blood-vessels, or the heart. The group of fibres that carry their impulses outward from the centre to the peripheral tissues compose the efferent or motor fibres. If these fibres end in muscles, the effect of their impulses is the production of a muscular contraction; if they end in a gland, they cause a secretion, the nature of the resulting action depending on the kind of tissue with which the nerve fibre is connected. It should be stated that there is no known difference in structure between afferent and efferent nerve fibres. Each, like a telegraph wire, can conduct an impulse in either direction.

But just as a telegraph wire with a sending apparatus at one end and a receiver at the other is arranged to conduct messages only in one direction, so the afferent and efferent nerve fibres, by the peculiarities of their end connections, are arranged so that normally they can convey effective impulses only in one direction. What we call a nerve or a nerve trunk consists of many hundreds or thousands of nerve fibres belonging usually to both the afferent and the efferent group. Though combined in one bundle, each fibre is physiologically independent and may act alone or in combination with others in the same trunk. In a muscle, on the contrary, the hundreds or thousands of muscular fibres of which it is composed act usually as a unit, all contracting together when the muscle is in action.

REFLEX ACTIONS. A large part of the beautiful adaptation and coördination of the different parts of our bodies is effected by the reflex activities of the nervous system entirely outside our conscious knowledge. The way in which these reflexes are produced is illustrated best by the simple reflex movements that can be obtained from a headless frog. If in such an animal, with its spinal cord intact, one of the toes is gently pinched, the leg will at once be drawn in toward the body. If the skin is stimulated by bits of paper moistened with dilute acetic acid, the leg of the corresponding side will be raised and the piece of paper will be wiped off by a neat movement involving the coördinate activity of a number of muscles. What happens in these cases is that the stimulus applied to the skin irritates the sensory nerve fibres and sends in a stream of nerve impulses to the spinal cord. These impulses are conveyed to the dendrites of certain motor nerve cells and arouse in them fresh impulses which are conducted outward through the efferent nerve fibres to the muscles. The original stimulus, or, more accurately, the nerve impulses to which it gives origin are thus, as it were, reflected in the nerve centres and sent to the peripheral tissues, whence the name of reflex action. Every such reflex involves the activity of at least two groups of nerve cells, one connected with the sensory fibres stimulated and one connected with the efferent fibres going to the muscles. Such reflexes may occur in all parts of the spinal cord and brain. A common reflex in ourselves, for instance, is the winking of the eye when its sensory surfaces are touched. As a rule we limit the term reflex action to those cases in which the element of consciousness is not involved. As a matter of fact, however, all of our conscious processes and mental activities are effected by a similar action of one nerve cell or unit on another, the mechanism in action being essentially similar to, although more complex than, the simple reflexes of the spinal cord. In a mammal as well as in a frog it can be shown that if a part of the spinal cord is severed from its connections with the brain, under such conditions that death does not result at once, the part of the cord below the injury will suffice to effect complex movements upon appropriate stimulation of the skin. To the uninformed such movements usually suggest consciousness, but the evidence of physiology proves conclusively that they are entirely unconscious reflexes.

It should be added that the outgoing impulse in reflex stimulation of the cord or brain may proceed through nerve fibres connected with other

tissues such as the heart-muscle, the plain muscle of the viscera or the glands, and the reflex effect, instead of exhibiting itself as a movement of the limbs, may take the form of a secretion, of a change in the heart beat, or of a constriction or dilatation of the blood-vessels. Owing to the complexity of the connections among the numerous nerve cells in the spinal cord and brain, it is evident that reflex effects may be widespread and very intricate. Certain definite paths or connections are inherited or become acquired during life from repeated use, so that the passage of a sensory nerve impulse that reaches the central nervous system is not hap-hazard, but for the most part along predetermined paths. The wonderful instincts of the lower animals may be regarded as complicated reflexes, and the unconscious regulation of the different parts of our body, especially the activity of the internal organs or viscera, is controlled in this way by the nervous system.

THE CIRCULATORY MECHANISM. The anatomical mechanism for the circulation of the blood and lymph consists of the heart, the blood-vessels, and the lymph-vessels. With regard to the blood we have the central fact that the powerful musculature of the heart serves as a force-pump driving the blood out from the ventricles through the circuit of the blood-vessels and back to the heart. The system of arteries branching from the heart resembles a tree with its central trunk and its vast number of branches of different sizes. As one goes outward from the heart toward the periphery, the arteries distributed to each organ become smaller and smaller until they end in minute capillaries. The combined area of these branches increases, however, toward the periphery, so that the sum of the areas of all the capillaries arising from the aorta is several hundred times as great as that of the aorta itself, just as the combined diameters of all of the twigs of a tree would much exceed that of the trunk. The quantity of blood being practically the same at all times, it becomes distributed as it goes out from the heart over a wider and wider area, or, to use a convenient figure, flows through a wider and wider bed. As a result of this fact the velocity of the blood-flow becomes smaller as we approach the capillaries. While in the aorta the blood may flow with a velocity of 300 millimeters per second, in the capillaries the velocity becomes reduced to $\frac{1}{2}$ millimeter. In the venous system the same general fact holds true. The capillaries unite into larger veins, and these into still larger ones, until finally all of the blood in the aortic system is collected into two large veins, the superior and the inferior vena cava, which open into the auricles. As a consequence the blood, as it flows back to the heart, passes through a path that becomes narrower and narrower, and its velocity increases proportionately. With regard to the velocity of the blood-flow, therefore, we can state that it is greatest in the large arteries and veins and least in the capillaries.

In the arteries, moreover, the blood is under a much greater pressure than in the capillaries and veins. From a cut artery the blood spurts to some distance, while from a cut vein the blood flows out quickly, but with little force. The cause of this difference is easily understood. In flowing through the vessels the blood encounters considerable resistance. Naturally this re-

sistance is greatest in the capillaries and in the small arteries and veins communicating with them. On account of the great resistance in the capillary region, known technically as the peripheral resistance, the blood is dammed up, retarded on the arterial side, stretching the elastic walls of the arteries and putting the blood under a considerable tension. In the capillaries the pressure of the blood is much less, and in the veins it becomes smaller and smaller as we approach the heart. Physiologically the most important part of the blood-circuit is in the capillaries. While flowing through these thin-walled and very minute vessels the blood fulfills its function of nourishing the tissues. At this point the blood, while still under some pressure, is flowing at its slowest rate, and the liquid part of it, the blood plasma, transudes through the thin walls and comes into direct contact with the tissues, thus forming the tissue-lymph. The oxygen carried by the red corpuscles of the blood is liberated in the capillaries and diffuses from the blood to the tissues, being transported to the latter while held in solution in the lymph. The lymph gives up its food materials and oxygen to the tissue cells and at the same time receives from them the waste products and carbon dioxide formed during their nutritive activity. The lymph is prevented from accumulating in the tissues by the fact that it is continually drained off by the system of lymphatic vessels. These vessels form a system parallel in course and structure to that of the veins. They begin in the tissues by small capillaries which unite to larger and larger vessels, forming eventually two main trunks that open into the veins of the neck. By this arrangement the excess of lymph is continually drained off and returned to the blood. The means by which the supply of lymph is regulated forms one of the most interesting and difficult subjects of study in modern physiology.

The heart and blood-vessels are not a fixed and rigid system. On the contrary, they are supplied with nerves through which the beat of the heart and the capacity and resistance of the blood-vessels may be reflexly adapted to the different conditions of the body as a whole, or the individual needs of its separate parts. The heart receives two sets of nerve fibres; one, the inhibitory fibres, are capable of slowing the heart-beat; the other, the accelerative fibres, quicken the rate. The small arteries, on the other hand, receive also two sets of nerve fibres; one, the vaso-constrictors, causes a diminution in size of the blood-vessels, while the other, the vasodilators, brings about an increase in size. The numerous conditions under which these regulating nerve fibres act are too complex to be described here. The mechanism is so adjusted as to control automatically the supply of blood to different organs under varying conditions of rest and activity.

THE RESPIRATORY MECHANISM. In mammals like ourselves the chief organ of external respiration is the lungs. When the inspiratory muscles are contracted the chest is enlarged and air flows into the lungs. When the expiratory muscles are contracted the chest is diminished in size and air is forced out of the lungs. In ordinary respiration the expiratory act is entirely passive; the chest, expanded by the action of the inspiratory muscles, sinks back into its normal position when these muscles cease to act. In forced breathing,

however, the expiratory muscles come into action. By means of these respiratory movements the air in the lungs is continually renewed, the supply of oxygen is maintained, and the carbon dioxide is removed. The oxygen contained in the air-sacs of the lungs diffuses through their thin walls, and, coming into contact with the blood, it unites chemically with the coloring matter of the red corpuscles, the hæmoglobin. In this combination it is carried to the heart, and thence distributed over the body through the various arteries. When the blood reaches the capillaries the compound of hæmoglobin and oxygen is broken or dissociated by the physical conditions there prevailing, while the liberated oxygen passes into solution in the blood plasma and lymph, and is thus conveyed to the tissues. On the other hand, the general nutritive change or metabolism of the tissues results in the formation among other things of carbon dioxide. This substance is a waste product, and if it accumulates in the tissues, brings on a suppression or perversion of the normal nutritive processes. Under normal conditions, however, it is rapidly removed by the lymph and blood. As the oxygen passes from the blood to the tissues by diffusion through the thin-walled capillaries, so the carbon dioxide as rapidly as it is formed streams in the opposite direction from tissues to blood. Each gas follows the physical law of diffusion from a point of greater to one of less tension. Within the blood the carbon dioxide is held mainly in chemical combination, partly with the proteids of the blood plasma, partly with the proteids of the blood corpuscles. When the blood reaches the lungs this loose chemical union breaks down, the carbon dioxide is liberated and diffuses into the air-sacs of the lungs, whence it is given off in the expired air. The process of respiration, therefore, may be divided into two parts, external and internal respiration. Under the former term we include all the processes involved in the movement of air into and out of the lungs, and the exchange of oxygen and carbon dioxide between the blood and the air in the lungs. By internal respiration we mean the exchange of oxygen and carbon dioxide between the tissues and the blood as well as the processes of nutrition by means of which the oxygen is used and the carbon dioxide produced. What we call arterial blood differs from venous blood in that it contains more oxygen and less carbon dioxide, and to this difference in the gaseous contents is due also the well-known variation in color, arterial blood having a scarlet tint, while the venous blood is purplish or crimson. The machinery for the movements of respiration, that is, the respiratory muscles, are under the control of the central nervous system. These muscles may be influenced within certain limits by direct voluntary effort; but a far more important factor is their unconscious or reflex regulation exerted through the respiratory nerve cells or nerve centre found in the medulla oblongata. By the activity of this centre the respiratory movements are kept continually in play and the extent of the respirations is adjusted to the needs of the body.

DIGESTION AND NUTRITION. The living matter of the animal body is characterized, as compared with plant protoplasm, by its limited powers of assimilation. While the latter can construct living matter from comparatively simple inorganic material, such as carbon dioxide, water,

and nitrogen containing salts, the former requires food in the more complex form of organic material. Since in the last analysis this organic food is derived from the plant kingdom, it may be said that the maintenance of animal life is only possible through the synthetic activity of plant protoplasm. All of our varied foods are found upon analysis to be composed of essentially the same materials united in different proportions. These constituent materials of our foods are known as food-stuffs and are usually classified as *proteids, fats, carbohydrates, water, and salts*. Of these substances the water, inorganic salts, and proteids are absolutely essential. The two former are necessary to the composition and reactions of the living tissues, but they do not directly furnish any energy to the body. The requisite amount of water is controlled by the sensation of thirst, and the proper proportions of the inorganic salts are provided in our foods without the necessity of any conscious selection on our part, except perhaps in the case of sodium chloride. Proteid foods have a different value. They are complex nitrogen-containing compounds which in the body are destroyed and reduced to much simpler substances, namely, carbon dioxide, water, and urea. This destruction of proteid is essentially an oxidation, and as much heat is given off in the process as would be liberated outside the body by burning proteid to the same end-products. Proteids are an absolutely necessary constituent of food, because they contain nitrogen in a form capable of being used in the construction of living matter. Fats and carbohydrates, since they contain no nitrogen, cannot be used alone in the synthesis of protoplasm. They are nevertheless valuable foods, since they are readily destroyed or burned in the body with the liberation of energy in the form of heat or muscular work. In a normal diet proteids, fats, and carbohydrates are usually combined in certain proportions, and experience as well as direct physiological experiments show that within limits the fats and the carbohydrates may be interchanged, and furthermore the greater the amount of these two substances used the less will be the amount of proteid required; as we say in physiology, fats and carbohydrates are 'proteid spacers.'

The nutritive history of these three energy-yielding foods may be summarized briefly as follows: The proteids in whatever form they may be taken are digested partly in the stomach by the action of the gastric juice and partly in the intestines by the action of the pancreatic juice. By the act of digestion the food proteids are converted into simpler and more soluble forms known as peptones and protoses, which are then absorbed into the blood and carried to the various tissues. Here they are utilized in part to form protoplasm, either to replace that broken down in metabolism or to supply material for growth. But much the larger part of the proteid is simply destroyed in the tissues with the transformation of some of its chemical energy into a corresponding amount of heat. The fats are prepared for digestion in the stomach, but undergo the important change that fits them for absorption after they are brought into contact with the pancreatic juice in the small intestine. After absorption they are found in the blood and lymph for a time, but soon pass into the tissues. Here they may be deposited as part of our normal store of

body-fat, but with the usual diet of adult life they are supposed to be completely burned. It is known from experiments that one gram of fat burned outside or inside the body yields as much heat as 2.2 grams of proteid. The carbohydrates include the starches and the sugars which from a nutritive standpoint have the same value. The starches form the bulk of our diet, and they are digested partly in the mouth by the action of the saliva, but mainly in the small intestine by the action of the pancreatic secretion. Under the influence of these secretions the starches are converted into a form of sugar, which is then absorbed into the blood. As the blood from the intestines passes through the liver this absorbed sugar is removed and again converted into a form of starch known as glycogen, which is deposited or stored in the liver cells. From time to time the glycogen is reconverted to sugar and given off to the blood. The regulating mechanism controlling this production and conversion of glycogen is so adjusted that under the normal conditions of life the blood always contains a nearly constant amount of sugar. Sugar, therefore, is the final form in which all of our carbohydrate food is brought to the tissues—and under the influence of the living matter it is eventually oxidized to carbon dioxide and water. In the long run, therefore, the final fate of our food is to be burned and furnish energy in the form of heat, muscular work, etc. The continual consumption of food is necessary to maintain the body temperature, and in the body we have very complex regulating mechanisms which control the loss of heat and to a certain extent its production, with the normal result that the temperature of the body remains nearly constant under all the varying conditions of life. It has been shown with scientific accuracy that all the detectible energy given off from the body is derived directly from the food consumed. The energy value of any food can, therefore, be determined by ascertaining the amount of heat produced by burning it, or more conveniently by ascertaining the heat value of proteids, fats, and carbohydrates, and then analyzing the food to determine how much of these three foodstuffs is contained in it.

THE CENTRAL NERVOUS SYSTEM. Some statements regarding the structure of the nervous system will be found in the beginning of this article. (Consult also the article on **NERVOUS SYSTEM AND BRAIN.**) At the base of the brain immediately adjoining the spinal cord we have the medulla oblongata. In this part of the brain are found certain important collections of nerve cells which control the movements of respiration, of the heart, and of the blood-vessels, their activity being entirely unconscious and under the influence of reflex stimulation. Collections of nerve cells connected with and regulating the action of physiological mechanisms are known as nerve centres, and in the medulla we recognize the existence of the three centres mentioned and designate them as the respiratory centre, the cardio-inhibitory centre, and the vaso-motor centre. They and other similar centres regulate the activity of the visceral organs, whose functions are discharged for the most part without our conscious knowledge or control. Injury to the medulla or severance of its connections with the spinal cord is fatal at once, owing to the destruction of the connections of the respiratory

centre with the respiratory muscles and the consequent inability to breathe. In the cerebellum we have an organ which seems to control the co-ordinated activity of the voluntary muscles. Extensive injury to the cerebellum, while not accompanied by actual paralysis, renders the animal incapable of executing orderly movements. If the animal survives the injury, the ability to make co-ordinated movements may be recovered more or less completely, but some awkwardness and muscular weakness persist as permanent results. In the nerve cells of the cerebral hemispheres we have the seat of the conscious sensations and of all the so-called psychic activities. Modern physiology has shown that different parts of the cerebral hemispheres have different functions. The optic nerve fibres end eventually in the occipital lobes, and here our conscious sensations of vision are mediated. A similar arrangement prevails for the other senses. In the cortex of gray matter covering the cerebral hemispheres there are in fact certain sense areas each of which mediates a different kind of consciousness. Other areas are connected with the various muscles of the body and form the centres through which our voluntary movements are executed, while in still other regions we have areas in which are stored the memories of past experiences and in which the factors of sensation are organized into the complex associations that characterize our mental life. Injuries to the brain may, therefore, be followed by quite different results according to the region involved. There may be a paralysis of this or that group of muscles, a loss of this or that primary sensation, or a disturbance or perversion of this or that group of memory associations. The so-called aphasias form noteworthy illustrations of these facts. Injury to certain limited areas of the brain may result in a partial or complete loss of the power of speech, or of the ability to understand either written or spoken language without any interference with vision or hearing. When defects of this character exist it is possible to locate the probable seat of the lesion, and not infrequently this knowledge has been made the basis of successful surgical operations.

HISTORY OF PHYSIOLOGY. The history of physiology is coextensive with that of medicine. Its relatively slow advancement through many centuries was closely associated with the growth of anatomical, chemical, and physical knowledge. In modern times, however, dating perhaps from the first part of the nineteenth century, physiology has become an independent science with a technique peculiarly its own, yet adopting more and more the exact methods that have arisen in the sciences of physics and chemistry. This development of physiology has been especially marked since investigators abandoned the idea of a special vital force controlling the phenomena of life and set themselves to the task of explaining the properties of living matter in terms of the forms of energy recognized as responsible for the phenomena of inanimate nature. The great facts in physiology, as in other subjects, have been discovered in a few cases only by the genius of individual workers. In most instances they have developed gradually as the result of the combined labors of many investigators, so that a history of the growth of the fundamental principles of modern physiology involves a discussion of the progress of the natural sciences in gen-

eral. Every important advance in physics and chemistry has influenced and will continue to influence the development of physiological knowledge. Some of the significant discoveries that belong especially to physiology and that can be traced more or less exactly to a definite period and individual observers are as follows: The circulation of the blood (Harvey, 1616-28); the existence of the lymphatic system of vessels (Aselli, 1622); the microscopic structure of the lungs, capillaries, glands, and other tissues (Malpighi, 1660-90); the discovery of the mammalian spermatozoon (Leeuwenhoek, 1678); the method of direct measurement of blood-pressure (Hales, 1732); the independent irritability of muscle (Haller, 1757); the discovery of oxygen and its functions in respiration (Lavoisier, 1775); the digestive action of gastric juice (Réaumur, 1752); the distinction between motor and sensory nerve fibres (Bell and Magendie, 1811-22); the discovery of the mammalian ovum (Von Baer, 1827); the true nature of the secretions of glands (Johannes Müller, 1830); the existence of enzymes, unorganized ferments, in the gland secretions and saliva—diastase (Leuchs, 1831); pepsin (Schwann, 1836); the nature of reflex actions (Marshall Hall, 1837); the electrical phenomena of muscle and nerve (Du Bois-Reymond, 1843); the existence of inhibition and inhibitory nerve fibres (Weber, 1845); the introduction of the graphic method in physiological experimentation (Ludwig, 1847); the existence of secretory nerve fibres (Ludwig, 1851); the existence of vaso-motor nerve fibres (Bernard, 1851); the existence and functions of glycogen (Bernard, 1857); the function of hæmoglobin in respiration (Hoppe-Seyler and Stokes, 1862-64); the localization of function in the cerebrum (Fritsch and Hitzig, 1870); the establishment of the fact of internal secretions (Brown-Séquard and others, 1891). For full information, consult: Foster, *Text-Book on Physiology* (Philadelphia, 1885); *The American Text-Book of Physiology* (2d ed., ib., 1900); Schäfer, *Text-Book of Physiology* (New York, 1900). For details of the histological features, consult Piersol, *A Text-Book of Normal Histology* (Philadelphia, 1901).

PHYSIOLOGY OF PLANTS. HISTORY. Up to the close of the seventeenth century nothing was known of the physiology of plants beyond the scattered impressions derived from the practical cultivation of plants in fields and gardens. Inasmuch as the physiology of animals was better known, the first study of the actions of plants was an endeavor to identify plant functions with those of animals. As the functions of animals were only superficially known, this attempted identification led oftentimes to most egregious errors. But as the nature of animal functions became better known, the essential identity of the processes in both sorts of living beings became more evident. At first the study of physiology was scarcely more than an enumeration of plant activities and their comparison with those of animals. Later, however, attempts were made to investigate the causes and conditions of the functions. For this a knowledge of anatomy was recognized as of prime importance. Deeper insight into physiology, however, demanded knowledge of physics and chemistry; and it was only when these two sciences underwent their pro-

found transformation and extension that explanations of plant phenomena began to be possible. Among the earliest investigations after the revival of learning were those made in Italy by Malpighi on the movement of sap, and those of Ray on the influence of light upon the colors of plants. About the same time in Germany Camerarius proved the necessity of pollen for the formation of fertile seeds.

Early in the eighteenth century Hales published his studies on the movement of sap and the evaporation of water from the leaves. Later in the eighteenth century came the investigations of Koelreuter, who added to the knowledge of sexuality in plants by his experiments on hybridization. It was in connection with these experiments that the relations of insects to pollination were first pointed out. Later (1793) these interesting relations were set forth at length by Christian Konrad Sprengel, whose famous "Das entdeckte Geheimnis der Natur" was scarcely appreciated until the contributions of Darwin had opened the eyes and understanding of naturalists to Sprengel's extraordinary work. About the same time Ingenhous showed that the green parts of plants when illuminated absorb carbon dioxide and eliminate oxygen, thus deriving the carbon which they need from the atmosphere. He also showed that the living parts of plants absorb oxygen, whether illuminated or not, and evolve carbon dioxide, thus establishing the fundamental facts of nutrition and respiration. This work was further confirmed by Senebier, who demonstrated that the decomposition of carbon dioxide takes place only in green organs. He also studied the influence of light upon the growth and green color of plants. By the beginning of the nineteenth century Nicolas Théodore de Saussure had shown that plants not only fix carbon from carbon dioxide, but also use the elements of water, which, with the mineral salts, are a necessary part of the food materials. Between 1822 and 1832 De Saussure and Goepfert established the connection between the respiration of plants and the development of heat in their bodies. Through the influence of Liebig, about the middle of the century, Ingenhous's clear exposition of the respiration of plants, which had been fairly established, was discarded, to be reinstated in confidence only after 1860 by the father of modern vegetable physiology, Julius von Sachs. Yet Liebig's valuable work in connection with the chemistry of foods and food materials of plants and Bous-singault's investigations in France, especially in relating the known facts to the empirical processes of agriculture, were of great service to both cultivators and physiologists. The year 1860 marks the rise of modern physiology, as indeed it does the rise of modern biology, many cooperating causes, the most notable of which was the publication of Darwin's *Origin of Species*, furnishing the impulse to renewed investigation.

SCOPE. As a science, plant physiology concerns itself with every inquiry relating to the functions and behavior of living plants. Certain aspects of physiology, namely the relation of living plants to the environment, physical (including soil, water supply, temperature, etc.) and biological (i.e. other plants and animals), have recently been separated from physiology proper and named ecology (q.v.). Physiology proper restricts itself to the activities of the individual

plant. Its study demands a previous knowledge of the anatomy (q.v.) and histology (q.v.) of plants, since familiarity with plant mechanism must precede the knowledge of plant function.

The functions of plants may be divided for convenience into certain groups. *First*, processes connected with the absorption of materials by the plant from the surrounding medium. Everything which enters the plant body must do so in solution. The plant depends, therefore, fundamentally upon water, which, with an infinite variety of solutes, both solid and gaseous, it absorbs. (See ABSORPTION.) *Second*, processes by which materials escape from the plant body. Gases, especially carbon dioxide and oxygen, are evolved (see AÉRATION; OSMOSIS); a great variety of materials are eliminated from the plant body by various processes of secretion (q.v.); and water is evaporated in great quantity by the surfaces of land plants. (See TRANSPIRATION.) *Third*, processes by which water and gases are moved about from the points of absorption or manufacture to the points of use, storage, or loss. But in spite of the fact that the movement of water was almost the first subject that attracted the attention of observers, no satisfactory explanation has yet been devised. (See CONDUCTION.) *Fourth*, processes of nutrition. Carbohydrate foods are made only by green plants under the influence of light, a power which is of the utmost importance, since the commercial supply of food and energy depends at present almost wholly upon green plants. The making of carbohydrates is fully described in the article PHOTOSYNTHESIS. (See CHLOROPHYLL; CHLOROPLASTS.) All plants, however, make proteid foods, when the necessary supply of carbohydrates, nitrates, and salts is furnished. Proteid synthesis is discussed in the article FOOD OF PLANTS. When proteid foods are at hand, either through manufacture or absorption, they undergo various changes before they become a part of the protoplasm. (For what little is known of these processes, see ASSIMILATION.) *Fifth*, processes concerned with the release of energy in the plant body or adjacent to it, in such a way that the kinetic energy can be applied to such work as the plant must do. For most plants, these processes constitute respiration. (See RESPIRATION IN PLANTS.) For a few plants fermentation (q.v.) seems to replace, in part at least, the normal respiration. *Sixth*, processes of repair and growth. One of the important activities of the plant is the formation of new material or the rearrangement of old into new parts. The diverse operations involved in this constitute growth (q.v.). *Seventh*, processes of perception and response. Every function of the plant is more or less influenced by the changes occurring in its vicinity, whether these be entirely outside of the body or only in adjacent parts. In order to adjust itself to these changes the plant must receive impressions of them, and these impressions must result in appropriate adjustment. The changes in the protoplasm corresponding to changes in the surrounding medium and the chain of effects thus initiated, are said to manifest irritability (q.v.). The visible alterations of the rate of growth (q.v.) or in movement (q.v.) are most striking evidences of irritability. See CHEMOTROPISM; GEOTROPISM; HELIOTROPISM; HYDROTROPISM; MOTOR ORGAN; RHEOTROPISM; STIMULUS; TENDRIL; TRAUMATROPISM.

PHY'SODON (Neo-Lat., from Gk. φύσα, *physa*, bellows, breath, bubble + ὀδούς, *odous*, tooth). An extinct sperm whale known by its skull, found in the Miocene formations of Patagonia. It differed from the modern sperm whale in having enamel-capped teeth in its upper jaws. See CETACEA.

PHY'SOSTIG'MA. See CALABAR BEAN.

PHYTOGEOGRAPHY. See DISTRIBUTION OF PLANTS.

PHY'TOLAC'CA (Neo-Lat., from Gk. φυτόν, *phyton*, plant + Neo-Lat. *tacca*, lac; from Per. *lak*, *luk*; Hind. *lāk*, from Skt. *lākṣā*, lac-insect, from *lākṣā*, hundred thousand, referring to the numbers of insects in each nest; so called from the crimson juice of the berries). A genus of about 20 species of dicotyledonous herbs and half-shrubs of the natural order Phytolaccaceæ, natives of warm parts of Asia, Africa, and America. *Phytolacca decandra*, the poke or pocan, a native of North America, now naturalized in some parts of South Europe, is occasionally cultivated for its young shoots, which are eaten like asparagus. The juice of the berries, which are about the size and color of black currants, is employed in the adulteration of wine. The young shoots of *Phytolacca acinosa* are boiled and eaten in the Himalayas. Under the name *Phytolacca esculenta* it has been introduced into gardens.

PHY'TOLAC'CA (in medicine). Official under either of two forms, the fruit or the root of *Phytolacca decandra* or poke, also called 'pigeon-berry' and 'garget root.' The fruit is a small, deep purple compound berry, nearly round, with a sweet and slightly astringent taste. The root is "large, branched, fracture fibrous, inodorous, sweetish, and acrid" (Potter). A fluid extract and a tincture are the preparations used, besides the berry and root. Poke has been used in ulcers, certain tumors, eczema, syphilis, and other skin diseases, chronic rheumatism, mastitis, tonsillitis, and pharyngitis. It has been used to decrease adipose tissue and thus reduce obesity since 1858. When given in large doses, phytolacca causes nausea, depression, vomiting, and purging. It lowers the rate of respiration and weakens the heart's action, and has caused convulsions.

PI. See PRINTING.

PIACENZA, pē'a-chēn'tsā. The capital of the Province of Piacenza, Italy, situated on the right

bank of the Po, two miles below its confluence with the Trebbia, 43 miles southeast of Milan (Map: Italy, D 2). The city is gloomy and desolate in appearance, though its thoroughfares are broad and regular. The Stradone is one of the most beautiful streets in Italy. Piacenza occupies a position of great strategic importance, and is fortified with solid walls and a strong castle. The Italian Government has strengthened and extended these fortifications by the construction of external defensive works, and by a formidable intrenched camp. The city has numerous fine palaces and churches. The attractive cathedral, an edifice in the Lombard-Romanesque style, founded in the eleventh century, is interesting for the grotesque character of its interior decorations. It has frescoes by Guercino and L. Carracci. The Church of Sant' Antonino, the original Cathedral of Piacenza, has been several times rebuilt. Santa Maria di Campagna has excellent mural paintings by Pordenone. The noteworthy San Sisto, an ancient church rebuilt in the Renaissance, gave its name to Raphael's Sistine Madonna. Among the other principal buildings are the immense Palazzo Farnese, begun in 1558 and never completed, once famous, but now serving as barracks; the fine Palazzo Municipale, dating from the thirteenth century, with its arched arcades and pinnacles; and the Palazzo dei Tribunali with curious courts, now in ruins. The principal square is the Piazza de' Cavalli, so called from the colossal bronze equestrian statues of the Dukes Alessandro and Ranuccio Farnese. There are a public library with over 130,000 volumes, a splendid theatre built in 1803, two new theatres, several hospitals, and an arsenal. Piacenza has manufactures of silk, cotton and woolen goods, hats, pottery, and machinery, and a trade in wine, grain, cheese, and marble from its quarries. Population (commune), in 1881, 34,987; in 1901, 36,064.

Piacenza, the ancient Placentia, was founded by the Romans in B.C. 219. In B.C. 200 it was plundered and burned by the Gauls, but recovered its prosperity with the construction of the Æmilian military road, which had its western terminus here. In the twelfth century it became a member of the Lombard League. In 1545 Piacenza, along with Parma, was erected into a duchy for the Farnese family. (See PARMA.) An important battle occurred here in 1746 in which the allied French and Spaniards were defeated by the Austrians. Consult Giarelli, *Storia di Piacenza* (Piacenza, 1889).

PIA MATER. See NERVOUS SYSTEM AND BRAIN.

PIAN'KISHAW. An Algonquian tribe, originally a band of the Miami, formerly residing chiefly upon the lower Wabash and claiming jurisdiction over most of southern Indiana and southeastern Illinois. When first known to the French, about 1670, they were in central Illinois, with the Miami and Illinois, and probably reached the Wabash about 1700. In 1832 they and the Wea sold all their claims in the east and agreed to remove to Kansas as one tribe. In 1867, having in the meantime consolidated with the remnants of the Illinois, they removed to the Indian Territory. They probably never numbered many more than 1000. In 1870 they were reported at 950, in 1895 at 800. In 1825 there were only 234 remaining in their original country,

with a few others residing in Missouri. The whole body of mixed-blood Piankishaw, Wea, Kaskaskia, and Peoria together now number only 180.

PIANO (It., soft), abbreviated *p*. A sign used in music to denote that the strain where the indication occurs is to be played with less than the average intensity of force: *pp*, or *ppp*, for *pianissimo*, signifies very soft, or as soft as possible. *Piano* is used in contradistinction to *forte* (q.v.), and the transition from the former to the latter is indicated by the sign <; the change from *forte* to *piano* is marked by the opposite sign >.

PIANOFORTE (It. *pianoforte*, from *piano*, soft + *forte*, loud). A percussive instrument consisting of wire strings struck by felt-covered hammers, operated by keys arranged in a keyboard. It was directly evolved from the clavichord and harpsichord (qq.v.). The history of the pianoforte proper begins with the year 1709. Scipione Maffei in the *Giornale dei letterati d'Italia* (1711) gives a detailed account of four instruments built by Bartolommeo Cristofori (not Cristofali, as generally stated until quite recently), named by him *pianoforte* and exhibited in 1709. The earlier clavichord and harpsichord admitted no gradation of the loudness of tone. In order to render musical performances more expressive by a contrast of soft and loud tones, three different men about the same time turned their attention to this matter. These were the just-mentioned Cristofori in Italy, Marius in France, and Schröter in Germany. Marius exhibited some harpsichords with hammer-action in Paris in 1716, but it is not known that Schröter ever built an instrument or had one built for him. Schröter claimed to have invented the hammer-action between 1717 and 1721. But not until 1738, when Cristofori's instruments had become famous, did he come forward with his claim; and he waited even till 1763 before he published for the first time a drawing of his invention.

Cristofori's earlier instruments show a very simple form of escapement: the return of the hopper to a perpendicular position is secured by means of a spring. But there is no check to prevent the rebound of the hammer after striking

ACTION OF CRISTOFORI'S PIANO.

the string. Two later instruments, built in 1720 and 1726 respectively, have a device for checking. In order to withstand the force of the impact of the hammer it was necessary to use thicker wire than in the harpsichord. This thicker wire increased the force of the tension, and necessitated a strengthening of the supporting framework. The hammers were covered with leather, and every key had a damper. Thus the fundamental principles of our modern grand pianos are all found, though in a simpler form, in the instruments of Cristofori. The compass of these instruments was four to four and a half octaves. The action of

Cristofori was adopted in its essential features by the famous organ-builder Silbermann. His first instruments failed to win the approbation of J. S. Bach, who criticised them for their weak treble and heavy action. This led Silbermann to spend some years in experiments which finally resulted in success.

Up to 1760 all pianofortes were built in the shape of the modern grand. In that year Zumppe a German workman, settled in London and began to build instruments in the square form, which at once became very popular. About the same time other makers settled in London and practically made the English capital the centre of the world's pianoforte trade. About 1790 Broadwood, working upon acoustic principles, discovered the fact that when struck at a certain point the string would yield a fuller tone. Accordingly he adjusted the hammers so as to obtain this result. He also transferred the wrest-plank (the block in which the tuning pins are held) to the back of the case, and in 1783 invented the pedals: one by means of which all the dampers could be raised, the other to soften the tone by dropping a piece of cloth over the strings. In these improvements Broadwood had the advice and assistance of Backer and Stodard. The action as perfected by Broadwood has come to be known as the English action, and is generally in use today.

ENGLISH GRAND PIANOFORTE ACTION.

Meanwhile German manufacturers had not been idle. Stein, a pupil of Silbermann, invented a new action, which has become famous as the Viennese action. While in Cristofori's (English) action the axis of the hammer does not change, because the hammer is fixed upon a lever separate from the key. Stein attached the hammer directly to the rear end of the key itself, causing a change of axis of the hammer when the key is struck. This produced the extreme lightness characteristic of the Viennese action. Stein's

STREICHER'S GRAND PIANOFORTE ACTION.

son-in-law, Streicher, in 1794 further improved this action and established a great reputation for his instruments. France was supplied chiefly with English pianos until Erard (a German whose name originally was Erhardt) settled in Paris in 1777. The Revolution drove him to London, where he made himself thoroughly familiar with English methods. Even after his return to Paris Erard continued to use the English action, but meanwhile he was seeking some improvement. His experiments resulted in 1821 in the double

escapement action, which soon spread the fame of Erard all over the world. The next important manufacturer in France was again a native German, Pape, of Hanover. Pape invented, in 1827, a down-striking action where the action is above

FRENCH GRAND PIANOFORTE ACTION.

the strings. He also substituted felt for leather in the covering of the hammers (1839). But this departure had already been made a few years previous by Babcock, of Boston.

In order to save space, some English makers toward the end of the eighteenth century conceived the idea of building pianos in an upright form. The first attempts consisted in nothing more than turning a grand or square instrument on one side. The first genuine upright was patented (1800) in England and the United States by John Isaac Hawkins, an Englishman living in the latter country. It is remarkable for containing most of the features which distinguish the modern upright. In the direct line of piano development, however, we owe a greater debt of gratitude to Southwell, who after fourteen years of experimenting exhibited the first upright piano that yielded practical results in 1807. This he called the 'Cabinet.' In 1811 he built another instrument which shows many decided improvements. Wornum still further improved this

ENGLISH UPRIGHT PIANOFORTE ACTION.

model by the introduction of diagonal stringing. The increased length of the strings yielded a more powerful tone. He also invented a new action principle (the so-called lever-check action), which was taken up and further improved by Pleyel of Paris, in which form it became known as the French action.

It must not be imagined that the pianoforte immediately upon its appearance at the beginning

of the eighteenth century superseded the harpsichord or clavicembalo. These instruments continued to be made; especially the clavicembalo kept its position in the orchestra throughout the century. Composers still wrote for the harpsichord. The earliest known composition written especially for pianoforte appeared in 1771. The composer, a certain Müthel, entitles it "Duetto für zwey Claviere, zwey Fortepiano oder zwey Flügel." But the technique is not different from that of the harpsichord. The first compositions written especially for the pianoforte and showing a technique characteristic of the new instrument are three sonatas (op. 2) by Muzio Clementi, published in 1773. From that time on composers began to study the peculiarities of the pianoforte and to employ the proper technique. The colossal pianoforte works of Beethoven were destined to revolutionize the manufacture of pianofortes. Many of his pianoforte works were beyond the capabilities of the instrument at that time. Thus he gave a powerful stimulus to piano-builders to increase both the compass and power of the pianoforte. In order to obtain power of tone the *thickness* of the strings had to be increased; to extend the scale the *number* of strings had to be increased. Manufacturers had to devise some frame capable of withstanding this enormous increase of tension. This led to the use of metal. In 1820 Allen and Thom patented a frame consisting of hollow metal tubes with brass and iron plates supported by heavy wooden crossbars. This was soon adopted by the leading manufacturers. Babcock of Boston in 1825 tried a cast-iron frame, and in 1832 Allen produced a frame that combined the string-plate, tension bars, and wrest-plank in one casting. This was still further improved by Chickering in 1837. In 1859 Steinway & Sons of New York added to the metal frame in one casting an agraffe, which is a small metallic support for the string, inserted between the bridge and the string for the purpose of preventing vibration in that part of the string. The same firm introduced also a double overstrung scale, which is obtained by dividing the strings into two sets, so that one set lies diagonally across the other.

Besides the improvements mentioned innumerable others have been and are still being made. From the four-octave instrument of Cristofori with a moderate tension, supported by a wooden sounding board, the modern pianoforte has developed into an instrument of tremendous tone-power with a compass of over seven octaves and a tension amounting to several tons. A modern pianoforte consists of the following parts: (1) The *frame*, now almost universally made of iron cast in a single piece. At the rear end is attached the *string-plate*, into which the strings are fastened. In the front there is the *wrest-plank*, into which the *tuning-pins* are set. Around these is wound the other end of the strings, and by turning these pins the tension of the strings is regulated. (2) The *sounding-board*, a thin piece of wood placed under the strings for the purpose of reinforcing the tone by means of sympathetic vibration. (3) The *strings*, made of steel wire, increasing in length and thickness from the treble to the bass. The lower ones are made heavier by being *overspun*, i.e. wound around with a coil of thin copper wire. For the very lowest tones only one wire is used (A_2-F_2). Then two strings for each tone (G_2-C); above that three

strings. (4) The *action*, the entire mechanism required for propelling the hammers against the strings. This includes the keyboard, a row of keys manipulated by the fingers. The keys corresponding to the natural tones are made of ivory, those corresponding to the chromatically altered tones, of ebony. When a key is pressed down the rear end rises and lifts a rod, called *jack*, which, in turn, throws the *hammer* against the string or strings. At the same time a *damper* is raised. The hammer, having struck the string, falls back immediately and is caught by a *check*, preventing a rebound. But as long as the key is pressed down the damper remains raised and thus allows the string to vibrate freely. (5) The *pedals*, levers pressed down by the feet. (a) The *forte* or *loud* pedal raises all the dampers, so that all the strings struck continue to vibrate even after the keys are released. (b) The *soft* pedal, which either throws all the hammers nearer to the strings, so that the striking distance is diminished by one-half, or shifts the hammers a little to one side, so that only a single string instead of the two or three is struck. (c) Some pianos have a third or *sustaining* pedal which does not raise *all* the dampers, but keeps raised only such as are raised by the keys at the moment this pedal is applied. (d) Recently many upright pianos have been built in which the application of a pedal interposes a strip of felt between the hammers and strings, so that only a very faint sound is produced. This is a great convenience while practicing. (6) The *case*. According to the shape of the case, pianos are classified as grand, square, and upright. The square form is no longer built, although many instruments of that shape are still in use. For use in private homes they have been entirely superseded by the uprights, which latter take up far less room. The grand pianos are built in various sizes, from the full concert grand, 8 feet 10 inches long, to the parlor or baby grand, 6 feet long. The cases are often very elaborately carved or even inlaid. There have been special instruments made that cost \$50,000.

For the sake of completeness, it is necessary to speak briefly about some inventions made in connection with the pianoforte. There is a device for increasing the volume of tone. This is the *æolian attachment*, an arrangement by means of which a current of air is directed against the strings, reinforcing the vibrations and thus causing a considerable increase in the volume and duration of the tone. In 1891 Dr. Eisenmann, of Berlin, invented the *electric piano*. Besides the ordinary hammer-action this instrument has an electro-magnet attached to each string. By pressing down the keys an electric circuit is closed, and the action of the electro-magnets causes a steady vibration of the strings. When the electric action is employed alone, the tone of the piano closely resembles that of the stringed instruments. By means of a special pedal any tone or chord can be sustained at will even after the fingers have left the keys. The electric action or the hammer-action may be employed each separately, or both may be combined. Many ingenious devices have been invented by which the piano can be played automatically, the most successful of which is perhaps the *pianola*. The great advantage of this invention is the control which the player can exercise over expressive interpretation by means of fine dynamic shading

and modifications of tempo. But, like all mechanical contrivances, it has its shortcomings, as the inability to bring out a melody in the middle voices. The idea of dumb keyboards is quite old. The *digitorium* or *dumb piano* is a portable box having five keys supported on springs. The use of it has always been strongly condemned by good musicians. In 1883 Mr. Virgil of New York invented the *Virgil practice clavier*, which is now extensively used and has several points of excellence. It has a complete keyboard. Each key when pressed down gives an audible click. There is a mechanism by means of which the player is enabled to cause a second click upon the release of a key. This is of great advantage in the practice of a legato touch. The performer need only see to it that the two clicks, the one produced by the release of a key, the other by the depression of the next key, coincide exactly. By means of a mechanical adjustment the action can be regulated at will from the very lightest pianoforte touch (2 ounces) up to 20 ounces. If used with judgment this is an excellent device for acquiring strength of the fingers. For exercises of a purely technical nature, the clavier is a valuable help. Some standard works dealing with the history of the pianoforte are: Rimbault, *History of the Pianoforte* (London, 1860); Paul, *Geschichte des Klaviers* (Leipzig, 1868); Gontershausen, *Der Klavierbau* (Frankfort, 1870); Ponsicchi, *Il pianoforte, sua origine e sviluppo* (Florence, 1876); Blüthner and Gretschel, *Lehrbuch des Pianofortebaues* (Weimar, 1886); Spillane, *History of the American Pianoforte* (New York, 1890); Hipkins, *The Pianoforte* (London, 1896); Bie, *A History of the Pianoforte and Pianoforte Players*, trans. from the German (London, 1899). See HARPISCHORD; MONOCHORD; PANTALEON; SPINET; VIRGINAL.

PIARISTS (from Lat. *pious*, pious), or **FATHERS OF THE PIOUS SCHOOLS**. A religious congregation for the education of the poor, founded at Rome at the end of the sixteenth century by Saint Joseph of Calasanza. He was a Spanish priest who, while in Rome, was struck with the imperfect and insufficient character of the education even of the higher classes, and decided to devote himself wholly to the meeting of this want. In 1597 he opened a school, with the assistance of a few like-minded friends, which rapidly increased until, seven years after, it numbered 900 pupils, and in 1613 as many as 1200. In 1617 the associates were recognized as a congregation by Paul V., who warmly approved the work. It spread during the seventeenth century into various European countries, and now numbers some 350 members, principally in Italy, Spain, and America. The general, who is chosen for nine years, resides in Rome, where general chapters are held every six years. The system of education adopted in their schools is very thorough, and in many ways resembles that of the Jesuits, with whom the Piarists have always had some affinity; on the suppression of the Society of Jesus they received many of its members into their ranks.

PIAS'SABA, or **PIAÇABA** (Port. *piassava*, *piacub*, from the native Brazilian name). A remarkable and important vegetable fibre produced by one or more species of South American palms. The greater part is furnished by the coquilla-nut palm (*Attalea funifera*), but Wallace states that

much of it is produced from a species of *Leopoldinia*, which he has named *Leopoldinia piassaba*. This quality is known commercially as Para piassaba. When the leaves decay, the petioles split up into cylindrical, dark-brown hard fibres varying from the thickness of a horsehair to the size of a quill. This material has been widely used in making coarse brushes, particularly those required for street-sweeping machines, for which purpose the coarsest have almost superseded all other kinds. The smaller fibres are used for finer brushes. In Brazil, cables, baskets, hats, and many other articles are made from this fibre. Large quantities are exported.

PIATIGORSK, pyät'-görsk'. A town in Russia. See PYATIGORSK.

PIATRA, pyät'ra. A town of Moldavia, Rumania, situated on the Bistritza, about 55 miles southwest of Jassy (Map: Balkan Peninsula, F 1). It has a large number of churches and monasteries and is an important centre in the lumber trade. Population, in 1901, 17,391.

PIATT, pi'at, DONN (1819-91). An American lawyer and journalist. He was born in Ohio, was educated at Saint Xavier College, Cincinnati, studied law, and was in 1851 elected judge of the common pleas court. During President Pierce's administration he was secretary of the Paris Legation, and for some months was acting chargé d'affaires. He enlisted as a private at the outbreak of the Civil War, and rose to the rank of colonel of volunteers, having served for the greater part of the war as adjutant-general on General Schenck's staff. After the war he was a newspaper correspondent, and founded the *Washington Capital*. His publications include: *Memoirs of the Men Who Saved the Union* (1887); and the poem, *The Lone Grave of the Shenandoah* (1888). Consult Miller, *Life of Donn Piatt* (1893).

PIATT, JOHN JAMES (1835—). An American journalist and poet, born in Milton, Ind. After studies at Capital University and Kenyon College, he was connected with Louisville and Cincinnati journals, and in 1871 was chosen librarian of the House of Representatives. From 1882 to 1893 he served as United States Consul at Cork and Dublin, Ireland. His poems are collected under many titles, among which are: *Poems of Two Friends* (with W. D. Howells, 1860); *The Nests at Washington* (with Mrs. Piatt, 1864); *Poems in Sunshine and Firelight* (1866); *Western Windows* (1869); *Landmarks, and Other Poems* (1871); *Idylls and Lyrics of the Ohio Valley* (1884-88-92); *At the Holy Well* (1887); etc. His prose works are less striking than his description in verse of the sentiments that underlie life in the Middle West.—His wife, SARAH MORGAN (BRYAN), born in Lexington, Ky., August 11, 1836, is known for many volumes of verse. She issued her *Collected Poems* in 1894.

PIAUHY, pē'ou-e'. A State of Northeastern Brazil, bounded on the east by the States of Ceará and Pernambuco, on the south by Bahia, on the northwest by Maranhão (Map: Brazil, J 5). On the Atlantic Ocean, on the north, it has a coast line of less than 10 miles. Area, 116,218 square miles. The surface consists mainly of sparsely wooded tablelands or *campos*, with lowlands in the north and west and along the rivers. There are no forests and the climate is dry and

hot. The chief rivers are the Paranyha and its tributaries. Agriculture is hindered by droughts and the scarcity of population, and the attempts to establish colonies of foreign immigrants have not been successful. Sugar, manioc, tobacco, and grain are raised in quantities hardly sufficient for domestic consumption. Cattle-raising is more extensive. Piauhy contains iron, aluminum, and some silver, but the deposits are not worked to any extent. The population was estimated in 1894 at over 300,000, mostly of mixed race. The capital is Theresina (q.v.), and the chief port is Paranyha.

PIAZZA ARMERINA, pĕ-ăt'sá är'má-rĕ'ná. A town in the Province of Caltanissetta, Sicily, 18 miles southeast of Caltanissetta. It stands on the crest and slopes of an isolated hill on the left bank of the Terranova. It is the residence of many nobles and landowners. The town has a Renaissance cathedral (1517), an old castle now used as a prison, a gymnasium, a seminary, a technical school, a theatre, and a picture gallery. The trade is chiefly in corn, wine, oil, fruits, and nuts. Piazza Armerina was founded by the Greeks. It was destroyed in 1160, but was soon rebuilt. Population (commune), in 1881, 19,591; in 1901, 24,379.

PIAZZA DELLA SIGNORIA, dĕl'lá sé'nyô-rĕ-á. See FLORENCE.

PIAZZA DEL POPOLO, pĕ'pô-lô. See ROME.

PIAZZA DI SPAGNA, spá'nyá. A square in Rome named from the Palazzo di Spagna, the residence of the Spanish ambassador. It is the centre of the foreign colony. Its most noted feature is the famous Spanish steps, leading to the Church of the Trinità de' Monti, and the resort of picturesquely clad artists' models.

PIAZZA NAVONA, ná-vô'ná. The second largest public place of Rome, laid out on the site of the Stadium of Domitian, on the ruins of which the surrounding buildings rest. The piazza, officially called the Circo Agonale, corresponds in size and shape to the ancient stadium, and contains three fountains and an obelisk in honor of Domitian, originally in the circus of Maxentius.

PIAZZA VENEZIA, vá-ná'tsé-á. See ROME.

PIAZZI, pĕ-ăt'sé, GIUSEPPE (1746-1826). An Italian astronomer, born at Ponte. He is known principally for his work at Palermo, where he went in 1781 to take the chair of mathematics, and where he established an observatory, which was put in working order in 1789. The first results of his observations were the corrections of some errors in the estimation of the obliquity of the ecliptic, the aberration of light, the length of the tropical year, and the parallax of various heavenly bodies. These results were published in 1792. On the night of January 1, 1801, he discovered a new planet, the first known of the planetoids (q.v.). Piazzi was able to obtain only a very few observations of it before it passed too near the sun to be visible; from which Gauss (q.v.) was nevertheless able to compute its orbit so that it was again found later in the year. Piazzi named it Ceres, after the ancient goddess of Sicily. In 1803 he published a catalogue of the fixed stars, the result of ten years' observations and far superior to any before published. It was rewarded with a prize from the Institute of France. In 1814 appeared a new and more

complete catalogue, containing 7646 stars, for which he was again rewarded with a prize from the French Institute. This catalogue is now regarded as his work of most lasting value to astronomy; and a new computation of his observations, using modern methods, is now being made. He also made researches into the nature of comets. In 1817 he was called to Naples as chief director of the Government Observatory, where he remained till his death.

PI-BESETH, pĕ-bá'sĕth. See BUBASTIS.

PIBROCH, pĕ-brôk (Gael. *piobaireachd*, art of playing on the bagpipe, from *piobair*, piper, from *piob*, bagpipe + *feair*, OIr. *fer*, man, connected with Lat. *vir*, Lith. *vicjras*, Lett. *vicrs*, Skt. *vira*, Goth. *vair*, AS., OHG., *wer*. man). The highest form of music written for the bagpipe. It consists of a series of variations written on a fundamental theme called *urlar*. These variations (generally three or four in number) increase in difficulty and speed, the last one, *creanluidh*, being a furious *presto*. What renders the notation of pibrochs particularly difficult is the great number of ornaments introduced, so that no definite rhythm can be discovered. A still greater difficulty is encountered because they make use of the eleventh overtone (a tone between *f* and *f#*), and thus cannot be reduced to any scale. Only in comparatively recent times (nineteenth century) has the expression of pibrochs in our notation been attempted. Before that, all music for the bagpipe was taught by a special system, the different tones having such names as *hodroho*, *hananin*, *hiechin*, etc. Niel Macleod published in 1828 at Edinburgh a collection of pibrochs in this peculiar notation. See BAGPIPE.

PICA. See PRINTING.

PICAN'DER. The pseudonym of the German poet Christian Friedrich Henrici (q.v.).

PIC'ARD. A corruption of Beghard. See BEGUINES.

PICARD, pĕ'kär', JEAN (1620-82). A French astronomer. In 1655 he succeeded Cassendi as professor of astronomy in the Collège de France. In 1666 he became a member of the Academy of Sciences. In 1671 he went to Uranienborg, on the island of Hven in the Sound, to determine the latitude and longitude of Tycho Brahe's observatory. The Paris Observatory and the *Connaissance des Temps* were founded by his efforts. He is known especially for his geodetic work in connection with determining by measurement the exact length of a degree of latitude.

PICARD, LOUIS BENOIT (1769-1828). A French dramatist, born in Paris. He began early to write plays, the first of which was *Le badinage dangereux* (1789). In many that he subsequently produced, he was both author and actor, and he had several collaborators. His plays, excellent pictures of the time, are satirical and vivacious, and have animated dialogue. The best include: *Encore des ménechmes* (1791), which made his reputation; *Médiocre et rampant* (1797); *Les marionnettes* (1807); *Les capitulations de conscience* (1809); and *L'intrigant maladroît* (1820). Several of them are printed in his *Théâtre* (8 vols., 1821) and *Théâtre républicain* (1832).

PIC'ARDY (Fr. *Picardie*). Formerly a province of France, now constituting the Department of Somme and parts of the departments of

Pas-de-Calais, Aisne, and Oise. Its principal town was Amiens. In 1167 Philip of Alsace, Count of Flanders, became Count of Picardy. It was acquired by Burgundy in 1435 and was united to France in 1477.

PIC'CADIL'LY. An important London street extending for about a mile between the Haymarket and Hyde Park Corner. One portion of the street contains many handsome shops, while the other is given up to fashionable residences. The name is referred to a kind of lace, fashionable in Queen Elizabeth's time, or to the collars so called during the reign of James I.

PICCINI, or PICCINNI, pè'chè'nè, Niccolò (1728-1800). An Italian composer. He was born in Bari, and studied music with Durante and Leo at the Conservatory of Sant' Onofrio, Naples. After producing a number of operas at Naples he removed to Rome, where he brought out *Allessandro nell' Indie* (1758); *Cecchina zitella, ossia la buona figliuola* (1760), which had an unparalleled success; and *L'Olimpiade* (1761). In 1776 he went to Paris, where Gluck was then the popular composer. Marmontel and others championed Piccini, and for several years a bitter controversy was carried on between the 'Piccinists' and the 'Gluckists.' Marmontel made a modern version of Quinault's drama *Roland*, and Piccini composed an opera on it, which had great success. He also composed *Iphigénie en Tauride*, a subject on which Gluck had also written an opera, *Atys*, and many others. He was professor in the Ecole de Chant (1783-91), was removed, and returned to Naples, where he suffered much annoyance from the espionage of the Government on account of his supposed revolutionary sympathies. Returning to Paris in 1798, he succeeded in obtaining from Bonaparte the inspectorship of music at the National Conservatory, but he did not live to begin the duties of his office. He is of interest to the musical historian, not so much for the quality of his work, or his ability as an artist, as for the important part he played in the overthrow of Logroscino (q.v.), whose buffo operas were then the vogue in Naples; and his own defeat (together with the ideas for which he stood) by Gluck (q.v.). He died at Passy, near Paris.

PICCININO, pè'chè-nè'nò, NICOLA (1375-1444). An Italian soldier, born at Perugia. He entered the band of condottieri led by Braccio da Montone, and after the death of their chief was elected to succeed him. For a short time he served Florence, but in 1425 went over to Filippo Maria Visconti, of Milan. Fighting in his interest, he defeated Carmagnola and the Venetians at Soncino and at Cremona (1431), and at Imola in 1434 gained a victory over the Venetians and Florentines. He captured Bologna in 1438. The city revolted from Piccinino's rule in 1443, and, overcome by reverses and the loss of his son, he died in the next year.

PICCIOLA, pè'chò-là. A pathetic story by Saintine (1836) which attained wide popularity and brought the author a decoration and the Montyon prize. It is the story of a prisoner in the time of Napoleon I., who beguiles the monotony of his confinement by caring for a plant which springs up between the stones of his cell, and which he calls *Picciola* (poor little one). The prisoner's life is saved in sickness by an infu-

sion of the leaves of the plant, which withers and dies after his release.

PIC'COLO (It., small). A flute of small dimensions, having the same compass as the ordinary flute, while the notes all sound an octave higher than their notation. In joyous as well as violent passages this instrument is sometimes very effective in an orchestra. The piccolo is usually made in three keys, C, D \flat , and E \flat , the latter two being used almost exclusively in military music. Piccolo is also the name of an organ stop. See FLUTE.

PICCOLOMINI, pik'kò-lóm'i-nè. The name of an old Italian family, whose ancestors settled at Rome, afterwards removed to Siena, and finally obtained the Duchy of Amalfi. Its most eminent member was **ÆNEAS SYLVIVS PICCOLOMINI**, who became Pope in 1458. (See PIUS II.) The family also gave several cardinals to the Church, and another pope, Pius III. (q.v.).—**OTTAVIO PICCOLOMINI** (1599-1656), first Duke of Amalfi, and fifth in direct descent from Pope Pius II., was a distinguished general in the Thirty Years' War on the Catholic side. He first entered the Spanish military service, and then as captain in a Florentine cavalry regiment aided Emperor Ferdinand II. against the Bohemians. He won distinction as a cavalry leader, served under Wallenstein, and at Lützen (1632) commanded the regiment of cuirassiers that met the last charge of Gustavus Adolphus. Wallenstein confided to him his secret designs against the Emperor; Piccolomini, however, communicated these designs to the Emperor, and after Wallenstein's assassination (1634) received as a reward for his fidelity a part of his estates. He took part in the battle of Nördlingen (1634), and in the following year was sent with a large force to aid the Spaniards in the Netherlands, where the French and Dutch were carrying all before them. Piccolomini speedily drove out the French, but his success against the Dutch was not so marked. In 1640 he was summoned to stay the Swedes, under Baner, who were threatening the hereditary possessions of Austria. He succeeded in checking the invaders in Bohemia and the Palatinate, but was badly beaten, along with the Archduke Leopold, in 1642 at Leipzig by Torstenson. He was now sent to the Netherlands to take command of the Spanish troops, and though the prestige of the Spanish infantry was destroyed by the Duke d'Enghien (the future Condé) at Rocroi (May 19, 1643), Piccolomini was again successful against both the French and Dutch till 1648, when he was anew summoned to Germany to encounter the victorious Swedes. The Peace of Westphalia put an end to the Thirty Years' War soon after. Piccolomini had now attained the rank of field-marshal. In 1650 he was raised to the dignity of a prince of the Empire. The King of Spain conferred upon him the order of the Golden Fleece, and bestowed upon him the Duchy of Amalfi, which had previously belonged to his family. With a fictitious son, Max, Piccolomini figures prominently in Schiller's *Wallenstein*.

PICCOLOMINI, DIE. The second play in Schiller's Wallenstein trilogy, produced in 1799. It represents Wallenstein in the midst of his preparations to make himself master of the throne of Bohemia, and takes its name from the two Italians, Octavio and Max Piccolomini. **Max,**

the son, is the devoted adherent of Wallenstein, while Octavio, the professed friend on whom Wallenstein relies, is in reality employed by the Emperor to watch him. Octavio in *Die Piccolomini* gradually involves Wallenstein in the web which leads to his death in the third tragedy of the series, *Wallenstein's Tod* (q.v.).

PICHEGRU, pèsh'gru', CHARLES (1761-1804). A French revolutionary general. He was born February 16, 1761, at Arbois, in the Department of Jura, and was educated at the college of his native town. He subsequently attended the military academy at Brienne, where he taught mathematics and had Bonaparte as one of his pupils. He entered an artillery regiment in 1783 and was for a short time in America. He was lieutenant when the Revolution broke out. Pichegru became an ardent republican, joined the army of the Rhine, and by his soldierly qualities soon attracted general attention and earned rapid promotion. In 1793 he became general of division and commander of the Army of the Rhine, and, in conjunction with the Army of the Moselle under Hoche, repeatedly defeated the Austrians and established himself securely in the Palatinate. After the arrest of Hoche, his success at the head of the combined Rhine and Moselle armies was not less decided. The rapidity and boldness of his manœuvres when in command of the Army of the North, in 1794, again disconcerted the Allies, and they were compelled to retreat beyond the Meuse. Pichegru completed the conquest of Holland in 1795 and ended a glorious campaign by organizing the Batavian Republic. He next visited Paris, and while there suppressed an insurrection in the suburbs of the city (April 1, 1795); but soon afterwards went to take command of the Army of the Rhine, and for some time displayed his usual skill and energy, crossing the river in the face of the enemy and capturing the fortress of Mannheim. But the state of affairs at Paris, combined with the flattering promises and bribes held out to him by the Prince of Condé, converted Pichegru into a secret partisan of the Bourbons. His inactivity, though prearranged with the Austrian generals, was not suspected till he suffered himself to be defeated at Heidelberg, and retreated, leaving Jourdan (q.v.) without support, thus compelling the latter also to retire. The suspicions of the Directory were confirmed by the seizure of Pichegru's correspondence, and he was immediately superseded by Moreau (q.v.). He then retired to his native town, where he lived till 1797, when he was elected one of the Council of Five Hundred. He soon became its president; but still continuing his intrigues with the Bourbons, he was arrested, and subsequently transported to Cayenne, but escaped in June, 1798, to England. He entered heart and soul into the Bourbon conspiracy along with Cadoudal (q.v.), the two Polignacs, and others, the primary object of which was the assassination of the First Consul. The conspirators secretly reached Paris, and there in 1804 Pichegru attempted to persuade Moreau, who was on bad terms with Napoleon, to join them, but without success. But the plans of the conspirators were soon known to the police, and an intimate friend of Pichegru, with whom he resided, sold the secret of his retreat to the police. Pichegru was suddenly arrested and taken to the Temple prison, February 28, 1804. On April 6 he was found dead in his bed.

The Royalists endeavored to fasten a charge of secret assassination on Napoleon, but it was generally, and probably correctly, believed that Pichegru strangled himself. Consult the biographies by Gassier (Paris, 1814), Pierret (ib., 1826), Vouziers (Dôle, 1870); also Montgaillard, *Mémoire, concernant la trahison de Pichegru* (Paris, 1804); and Daudef, *La conjuration de Pichegru, etc.* (ib., 1901).

PICENUM. One of the ancient divisions of Middle Italy, extending along the Adriatic from the Aesis (now Esino) to below the Vomano (now Vomano) River and bounded on the west by Umbria, Sabinum, and Vestinum. It was anciently inhabited by the Umbrians, who were conquered by the Sabines, under whom the name Picenum was acquired. In 268 the district was reduced by the Romans to the condition of a dependency and many of its inhabitants colonized in the town of Picentia. In Asculum, the old capital of Picentium, in B.C. 91, occurred the outbreak of the war of the Italian Confederacy against Rome. Under Augustus Picenum formed the fifth political region of Italy.

PICHICIAGO. See ARMADILLO and Plate of ANT-EATERS.

PICHINCHA, pé-chèn'chá. A volcano of the western range of the Andes in Ecuador, situated a few miles northwest of Quito (Map: Ecuador, B 3). It is an irregular mass of peaks, the highest of which, Huahua-Pichincha, has an altitude of 15,918 feet. Its crater is over 2000 feet deep; it is dormant, there having been no great eruption since 1660. On its slopes, on May 24, 1822, was fought the battle which secured the independence of the Republic.

PICHLER, pik'lér, ADOLF VON (1819-1900). An Austrian poet and naturalist. He was born at Erl in Tyrol, studied at Innsbruck and Vienna, published his first volume of poems in 1846, and in 1848 fought as an Austrian volunteer in the Italian campaign with great bravery. In 1867 he was appointed professor of mineralogy and geology in the University of Innsbruck. He wrote on the geology of the Alps and of Tyrol, but is better known as the Tyrolean poet, author of *Frühlieder aus Tirol* (1846), *In Lieb' und Hass* (1869; 3d ed. 1900), *Vorwinter* (1885), and *Spätfrüchte* (1896). Valuable autobiographic material is contained in his *Aus den März- und Oktobertagen zu Wien, 1848* (1850), and *Aus dem wälsch-tirolischen Kriege* (1849). Consult Prem, *Adolf von Pichler, der Dichter und Mensch* (Innsbruck, 1901).

PICHLER, KAROLINE (1769-1843). An Austrian novelist, born in Vienna. Her first novels, *Gleichnisse* (1800), *Oliver* (1802), *Leonore* (1804), *Ruth* (1805), possessed slight merit; *Agathokles* (1808), her best work, was meant to disprove the heresies of Gibbon's *Decline of the Roman Empire*. Succeeding novels were chiefly historical in matter, patriotic in purpose, and diffuse in style; e.g. *Die Grafen von Hohenburg* (1811), *Die Belagerung Wiens* (1824), *Die Schweden in Prag* (1827), *Henriette von England* (1832). She also wrote society stories, *Frauenwürde* (1808), *Die Nebenbuhler* (1821), *Zeitbilder* (1840), which, like her autobiographical *Denkwürdigkeiten* (1844), are wearisome. Her works are in 60 vols. (1845).

PICHURIC ACID. See LAURIC ACID.

PICIDÆ, pís'i-dê (Neo-Lat. nom. pl., from Lat. *picus*, woodpecker). The family of woodpeckers (q.v.).

PICK, BERNHARD (1842—). A Lutheran clergyman, born at Kempen, in Prussia. He studied in Berlin and at the Union Theological Seminary, New York City. In 1868 he entered the Presbyterian ministry, and, after having held several pastorates in that Church, he joined the Lutheran denomination in 1844. Besides contributing to the *Cyclopædia of Biblical, Theological, and Ecclesiastical Literature*, the *Cyclopædia of Religious Knowledge*, and many periodicals, his publications include: *Luther as a Hymnist* (1875); *Life of Christ According to Extra-Canonical Sources* (1887); and *The Talmud, What It Is and What It Says About Jesus and the Christians* (1887).

PICKELHERING, pik'el-hä'ring. A stock fool in the drama. The name was probably first assumed in the early part of the seventeenth century by Robert Reynolds, who traveled through Germany with a company of strolling comedians, and created a type which maintained itself until the eighteenth century.

PICK'ENS, ANDREW (1739-1817). An American soldier, born at Paxton, Pa. He removed with his parents to the Waxhaw settlement, S. C., in 1752, and fought in the Cherokee war in 1761 as a volunteer. At the beginning of the Revolutionary War he became captain of a militia company, and by successive promotions soon attained the rank of brigadier-general of South Carolina troops, gaining great distinction as a partisan leader. In 1779 he defeated a superior force of loyalists under General Boyd at Kettle Creek, participated on June 10th in the battle of Stone Ferry, and defeated the Cherokees at Tommassee. He commanded the militia at the battle of Cowpens, January 17, 1781, twice rallying them after they had been driven back, and for his gallantry received a sword from Congress. At the battle of Entaw Springs, September 8, 1781, he was in command of the Carolina militia, and in 1782 forced the Cherokees to relinquish their claim to a large tract of land now included in the State of Georgia. After the war he was a member of the South Carolina Legislature from 1783 to 1794; sat in Congress in 1793-95; was a member of the State Constitutional Convention; became major-general of militia in 1795; and was again in the Legislature in 1801 and 1812. He was commissioner on many occasions to treat with the Indians. His son, ANDREW, a lawyer, was Governor of South Carolina in 1816-18, and died in Mississippi in 1838.

PICKENS, FORT. See FORT PICKENS.

PICKENS, FRANCIS WILKINSON (1805-69). An American statesman and diplomat, born at Togadoo, Saint Paul's Parish, S. C. He studied at South Carolina College, was admitted to the bar in 1829, and three years afterwards was elected to the State Legislature, where he soon became prominent as an advocate of nullification and the doctrine of extreme States' rights. From 1834 until 1844 he was a member of Congress, in 1850-51 a delegate to the Nashville Southern Convention, and in 1854 presiding officer of the South Carolina State Convention, and in 1856 a delegate to the General Democratic Convention in Cincinnati. The next year he was appointed

United States Minister to Russia, but returned to America in 1860, and soon afterwards was elected Governor of South Carolina. He zealously supported the secession movement, and immediately after the passage of the ordinance by the Charleston Convention began to organize an independent government. To this end he demanded the surrender of all Federal property within the borders of the State, and when Major Anderson refused to give up Fort Sumter, began to erect the batteries which afterwards, under the orders of the Confederate Government, caused its reduction.

PICKEREL (double diminutive of *pike*). One of the smaller members of the pike family, Lucidae. The Eastern or pond pickerel, jack, or green pike (*Lucius reticulatus*) is common everywhere east and south of the Allegheny Mountains. In Tennessee and Arkansas it reaches a length of 24 inches and is golden green marked with numerous dark lines and streaks, which are mostly horizontal, and by their junction with one another produce a reticulated appearance. The banded pickerel (*Lucius Americanus*), of the coast streams from Massachusetts to Florida, is 12 inches long and dark green, with about 20 blackish curved bars on the sides. The little pickerel (*Lucius vermiculatus*) occurs throughout the Mississippi Valley, is 12 inches long and very variable in color, with an irregular network of fine curving streaks on the sides. The common pike is also frequently called 'pickerel.' The habits and mode of catching are the same as in the case of the pike (q.v.). See Plate of NEEDLE-FISH, PIKES, ETC., and Colored Plate of AMERICAN GAME FISHES, accompanying article TROUT.

PICKEREL FROG. A small light brown frog (*Rana palustris*) with dark square or oblong brown blotches in two rows on its back, and the head marked by a dark line which runs from the nostril to the eye. This frog dwells in the Eastern United States, especially in mountainous parts, and occurs mainly about springs.

PICK'ERING, CHARLES (1805-78). An American naturalist, grandson of Col. Timothy Pickering, born at Starucca Creek, Pa. He graduated at Harvard in 1823, and at the Medical School three years later. After practicing for some years he was, in 1838, appointed naturalist of the United States Exploring Expedition under the command of Lieut. Charles Wilkes (q.v.). In 1843 he visited Egypt, Arabia, East Africa, and India. He published: *The Races of Man and Their Geographical Distribution* (1848); *The Geographical Distribution of Animals and Plants* (1854); and *The Chronological History of Plants; Man's Record of His Own Existence Illustrated Through Their Names, Uses, and Companionship* (1879).

PICKERING, EDWARD CHARLES (1846—). An American astronomer, born in Boston. He graduated at the Lawrence Scientific School, Harvard, in 1865, and for the next two years was instructor of mathematics there. From 1867 until 1877 he was Thayer professor of physics at the Massachusetts Institute of Technology, but in the latter year he returned to Harvard as professor of astronomy and director of the observatory. At the Institute of Technology in 1869 he established the first physical laboratory for general instruction in the United States, and later, in connection with his work at Harvard, established an

observatory at Arequipa, in Peru. He devoted particular attention to the study of light and the spectra of the stars and published the results of his observations in the *Annals of the Harvard Observatory*. He also wrote *Elements of Physical Manipulation* (1874).

PICKERING, JOHN (1777-1846). An American linguist and lexicographer, son of Timothy Pickering, born in Salem, Mass. He graduated at Harvard in 1796, studied law with Edward Tilgham in Philadelphia, was Secretary of Legation in Lisbon until 1799, and then became private secretary to Rufus King, Minister to England. He practiced law in Salem, Mass., from 1801 to 1827, was City Solicitor of Boston (1827-46), and during his service in the State Legislature took a prominent part in revising the Massachusetts general statutes. He was president of the American Academy of Sciences, first president of the American Oriental Society, an able linguist, and, like his father, particularly interested in the languages of the North American Indians. He wrote *A Uniform Orthography for the Indian Languages* (1820), *Remarks on the Indian Languages of North America* (1836), *Vocabulary of Words and Phrases Supposed to be Peculiar to the United States* (1816), and a *Greek and English Lexicon* (1826; 3d ed. 1846), as well as many monographs on ancient and international law. Consult the biography by his daughter, Mary Orne Pickering (Boston, 1887).

PICKERING, TIMOTHY (1745-1829). An American statesman. He was born at Salem, Mass., July 17, 1745, graduated at Harvard in 1763, and was admitted to the bar in 1768. In 1773 he drafted for the town of Salem a paper entitled *State of the Rights of the Colonists*, and in the following year the memorial of the citizens of Salem to General Gage in regard to the Boston Port Bill. In 1776 he joined the Revolutionary Army and led an Essex County regiment to Tarrytown, N. Y. In the following year he took part in the battles of Brandywine and Germantown, and was appointed a member of the Congressional Board of War. In 1780 he was appointed Quartermaster-General of the army and retained the office until its abolition in 1785. Upon his retirement from the army, he engaged in business in Philadelphia, but two years later removed to the Wyoming Valley and became involved in the disturbances of that region, where he was instrumental in maintaining order and quiet. He settled the territorial disputes between Pennsylvania and the inhabitants of the Wyoming Valley, and organized Luzerne County, which he represented in the Pennsylvania Constitutional Convention of 1789. In 1790 he was commissioned by President Washington to negotiate a treaty with the Six Nations, which he did successfully, and later performed a similar service with the Indians of the Northwest. In 1791 Colonel Pickering was appointed Postmaster-General of the United States, which office he held until 1795, when he was appointed Secretary of War. Pickering signalized his administration by establishing a military school at West Point and by supervising the construction of the frigates *Constitution*, *United States*, and *Constellation*. Upon the resignation of Edmund Randolph near the end of 1795, Colonel Pickering was appointed Secretary of State, which office he held during the remainder of Washington's term and through the great-

er part of Adams's administration. In 1800 he was abruptly removed on account of a serious disagreement with the President growing out of the difficulties with France over the X. Y. Z. correspondence (q.v.). He then retired to his uncleared lands in what is now Susquehanna County, Pa., but was in poor circumstances, and some of his Massachusetts friends prevailed upon him to return to his native State, where in 1802 he became Chief Justice of the Court of Common Pleas. In the following year he was elected to the United States Senate, where he served until 1811. As a member of the House of Representatives he served until 1817, when he refused a renomination and again retired to private life. He died at Salem, January 29, 1829. Pickering wrote numerous political papers, including a *Review of the Correspondence Between John Adams and William Cunningham*. A biography of Colonel Pickering in 4 vols. was published by Octavius Pickering and C. W. Upham (Boston, 1867-73).

PICKERING, WILLIAM (1796-1854). An English publisher. After serving for ten years in a Quaker publishing house in Cornhill, London, he opened a bookshop of his own in Lincoln's Inn Fields (1820). Adding publishing to the business, he subsequently moved to Chancery Lane (1824), and to Piccadilly (1842). For printing he employed the Chiswick Press. About 1830 he adopted the trade-mark of Aldus, the famous Italian printer—an anchor entwined with a dolphin, to which was added the motto, *Aldi Discip. Ang.* Among his notable undertakings were the *Diamond Classics* (a series of delicate volumes in 48mo and 32mo, issued between 1821-31); and reprints of different versions of the Book of Common Prayer, between 1549 and 1662 (6 vols., 1844), the typography of which has probably never been surpassed. Among his sumptuous publications may be cited Walton's *Compleat Angler*, illustrated by Stothard and Inskipp (2 vols., 1836). He also projected the Aldine edition of English poets. After his death the business was carried on by his son, BASIL MONTAGUE PICKERING (1836-78), who, among several reprints, issued a fac-simile of the first edition of *Paradise Lost*. In 1878 the firm came to an end.

PICKET (OF. *piquet*, *piequet*, Fr. *piquet*, peg, diminutive of OF. *picue*, *pieque*, Fr. *pique*, pike, probably from Lat. *spica*, point, ear of grain, tuft of a plant, pin). A military term having several meanings. Specifically it is used as describing a small body of men posted at some point beyond the general line of sentries for the purpose of observing the motions of an enemy, or giving timely notice in case of impending attack. (See OUTPOST.) Formerly, in the British Army the term was applied to a military punishment, in which the culprit was held by the raised arm in such a position that his whole weight fell on one foot, which was supported on a picket with a blunt point. The time the man thus stood was proportioned to the offense. It was a peculiarly inhuman form of punishment, and is now strictly forbidden. In camp, horses are said to be picketed when secured to a picketing rope. Pegs of wood or iron used to secure tent ropes are also called pickets. In all English garrisons and camps a small body of men under a corporal or sergeant, and known as the garrison picket, patrols the lines or city as a disciplinary check on

the troops, and a support to the military police (q.v.). See **ADVANCE GUARD**; **OUTPOST**; **PATROL**.

PICKETING. In labor wars, the practice pursued by trades-unions of stationing outposts near the place of employment where a strike is in progress, for the purpose of dissuading workmen not affiliated with the union from taking service with the employer against whom the contest is being waged. In theory a matter of persuasion, picketing, in strikes where feeling runs high, is apt to assume the form of intimidation against non-union workmen, and as such has come within the cognizance of the police, who, as a rule, have been able to prevent the effective execution of picketing duty by the exercise of the authority vested in them to prevent open disorder and loitering in the public highways. Legally the question is a mooted one, and the real point in most cases that appear before the courts is one of fact as to whether the union watchers have overstepped their right of exercising moral persuasion and have resorted to force. In recent judicial decisions a double trend is apparent. On the one hand, the judges, by a broad use of the power of injunction (q.v.) have declared against any action on the part of strikers partaking of the nature of intimidation. In reaction against this view, some courts have shown a tendency toward permitting the peaceable propaganda of their views on the part of strikers, and where picketing has been carried on by small groups of men, scarcely to be suspected of exercising force against non-union workers, to countenance such action as falling within the legitimate exercise of every man's right to express his views in a peaceable manner. See **STRIKE**.

PICKETT, GEORGE EDWARD (1825-75). An American soldier, born in Richmond, Va. He graduated at West Point in 1846, served in the Mexican War, and was brevetted first lieutenant for gallantry at Contreras and Churubusco, and captain for his conduct at Chapultepec. He became first lieutenant in 1849, and captain in 1855. In 1856, while serving in the Territory of Washington, he occupied San Juan Island and prevented the landing of British troops. He resigned from the Federal Army June 25, 1861, and became major of artillery in the Confederate Army. On July 23d he was made colonel in the provisional army and was assigned to command in the lower Rappahannock. He became brigadier-general on February 28, 1862, and at Seven Pines held his ground stubbornly, though outnumbered. He was seriously wounded at Gaines's Mill, and on his recovery was made major-general, in October, 1862. At Fredericksburg he held the centre of the Confederate line. At Gettysburg his division reached the field on the morning of the third day, July 3d, and formed the centre of the attacking line in the famous assault on Cemetery Ridge. (See **GETTYSBURG**.) In September, 1863, General Pickett was given charge of the Department of North Carolina, and made an unsuccessful demonstration against New Berne in January, 1864. When he returned to Virginia his division recaptured the Confederate lines at Drewry's Bluff in June. He was sent to Lynchburg to oppose Sheridan's cavalry in March, 1865, and was badly defeated at Dinwiddie Court House and Five Forks, but rallied his men and checked the pursuit. After the close of the war

he engaged in business at Richmond, where he died.

PICKING, HENRY FORRY (1840-99). An American naval officer, born in Somerset County, Pa. He graduated at the United States Naval Academy in 1861, and in the Civil War served successively in the North Atlantic Blockading Squadron, the East Gulf Blockading Squadron, and the South Atlantic Blockading Squadron, being promoted to be a lieutenant in July, 1862, and being placed in command of the *Nahant* in 1865. In July, 1866, he was promoted to be lieutenant-commander, and in January, 1875, to be commander. He commanded the *Kearsarge* in 1879-81, was Lighthouse Inspector in 1881-82, and commanded the United States naval force in the Northwestern Lakes in 1887-89. In August, 1889, he was promoted to be captain, in November, 1898, to be commodore, and in March, 1899, to be rear-admiral. He succeeded Rear-Admiral Howison as commandant of the Charlestown Navy Yard on March 25, 1899, and died there in the following September.

PICKLES (from Ger. *pökel*, *bökel*, pickle, brine). Although the term *pickled* is applied to animal substances, such as beef, pork, and fish, preserved in salt, yet pickles are generally understood to be the various kinds of fruits or vegetables preserved in vinegar. The process employed is first to wash the articles intended for pickles in clean cold water, and afterwards to soak them for a few days in a strong solution of salt in water. They are next taken out, and if fruits or roots, dried in a clean cloth; but if vegetables, such as cauliflower, etc., they must be well drained, and then placed in the vessels intended to hold them, a few peppercorns, or any other spice which is suitable, being sprinkled in from time to time. When the vessel is so far filled that it will hold no more, boiling vinegar is poured in until it is quite full, and tightly covered up. Many persons prefer to boil the spices, of whatever kind used, in the vinegar; and some add the vinegar cold to such vegetables or fruits as are of a naturally soft substance, because, except in the case of green walnuts, and one or two other fruits, extreme softness is objectionable in pickles. When the materials to be pickled are naturally green, as in the case of gherkins or small cucumbers, French beans, etc., it is considered very desirable to preserve their color as much as possible; and it is sometimes very successfully accomplished by steeping vine, cabbage, spinach, or parsley leaves in the vinegar, by which their color is imparted through the vinegar to the pickles. But this requires great care and patience, more, indeed, than is generally thought worth applying to it, and dealers consequently resort to very reprehensible methods of coloring their pickles, such as boiling the vinegar in copper vessels, and thereby forming an acetate of copper, which is green; or even directly adding that salt to the pickles. Many serious accidents have resulted from the presence of this poison. Many fruits are preserved by pickling, in which case no salt is used and sugar is added to the vinegar. Pears, plums, and blackberries are particularly palatable when prepared in this way. The principal vegetables commonly preserved by pickling are cauliflowers, cucumbers, gherkins, onions, mushrooms, and nasturtiums. *Piccalilly*, or Indian pickle, is a mixture

of various vegetables, as cucumbers, onions, cauliflower, and of spices, pickled together. *Chouchou* is a mixed pickle to which mustard is added. See FOOD, PRESERVATION OF.

PICKLE WORM, or **PICKLE MOTH**. A moth of the family Pyralidæ (*Diaphania nitidalis*), which occurs abundantly throughout the Southern and Western United States, and lives, in the larval state, in cucumbers, boring into them and destroying them when about half-grown, or at about the stage when they are preferably used for pickles, whence the popular name. It also feeds upon other cucurbitaceous plants, such as the squash, cantaloupe, and melon. The early generation of this insect feeds upon the leaves of the same plants, and there is little doubt that by carefully spraying with arsenicals before the fruit is grown the insect may be held in check.

PICK'NELL, **WILLIAM LAMB** (1852-97). An American landscape and marine painter, born at Hinesburg, Vt. He studied under George Innes at Rome from 1873 to 1875, under Gérôme at Paris in 1875, and under Robert Wylie in Brittany until 1879. He returned to America in 1882, passing his summers at Anquisham, Mass., his winters in England and Southern France. He became a member of the Society of American Artists in 1880, and of the Society of British Artists in 1884. He received medals at Boston (1881 and 1888), and a gold medal at the Paris Salon with his "Morning at the Loing" (1895). He died at Marblehead, Mass. His work is natural and unaffected, and shows a fine feeling for line, brilliant light effects, and rich color, though he also succeeded well with the shimmering mist in his gray marines. His chief works include: "Route de Concarneau" (1880), Coreoran Gallery, Washington; "Borders of the Marsh" (1880), Academy of Fine Arts, Philadelphia; "A Stormy Day" (1891); "Coast of Ipswich" (1882), in the Boston Museum; "Sunshine and Drifting Sand" (1895); "Bleak December" (1887), in the Metropolitan Museum, New York; "A Sultry Day" (1884); "Wintry March" (1885); "November Solitude" (1887); "Among the Olives" (1894); "Midwinter on the Littoral" (1895); "Route de Nice" (1896).

PICKWICK CLUB, **THE POSTHUMOUS PAPERS OF THE**. A novel by Charles Dickens (1837). It was undertaken to accompany a set of comic sketches by Seymour, appearing as a serial in 1836 and 1837, and established Dickens's literary success. A work of humor throughout, giving rather loosely connected accounts of comical characters in many walks of life, linked together by the adventures of the amiable Mr. Pickwick, chairman of the Club of Solemn Stupidity. Mr. Pickwick, with his associates, Tupman, Winkle, and Snodgrass, pursues his investigations in various parts of England, in the course of which he runs across the inimitable Sam Weller, Sam's father, the coachman, the 'shepherd,' Stiggins, the hospitable Mr. Wardle, of Dingley Farm, impecunious Alfred Jingle, and Job Trotter, the 'portable engine,' the buxom Mrs. Bardell, who brings the famous breach of promise suit, Mr. and Mrs. Leo Hunter, and other minor characters.

PICO, pē'kō. One of the Azores Islands (q.v.), belonging to the central group. It is 36 miles long and 4 to 10 miles wide, with an area of 176 square miles. It is traversed by a volcanic

ridge, which rises 7613 feet high in the peak (Pico), whence the name of the island. The chief product is wine. Population, in 1900, 16,626.

PICO DELLA MIRANDOLA, dē'l'la mè-rān'-dō-lā, GIOVANNI, Count (1463-94). An Italian philosopher and theologian. He was born February 24, 1463, the son of the sovereign prince of Mirandola and Concordia. From his fourteenth to his sixteenth year he studied at the University of Bologna, and afterwards visited the principal schools of Italy and France, everywhere distinguishing himself by his extraordinary facility of acquisition. He is said to have known more than twenty languages; he was familiar with the different phases of the scholastic philosophy, and was also versed in mathematics, logic, and physics. At the age of twenty-three he returned to Rome, when Innocent VIII. was pontiff, and immediately sought an opportunity of showing his learning in the most striking manner, by publicly posting up no fewer than 900 theses or propositions in logic, ethics, physics, mathematics, theology, science, and cabalistic magic, drawn from Latin, Greek, Jewish, and Arabic writers, offering to maintain an argument on each against all the scholars of Europe, and undertaking to pay the expenses of those who came from a distance. Pico presumptuously entitled his theses *De Omni Re Scibili* (On Everything that can be Known). Pope Innocent VIII. refused to allow Pico to carry on this discussion, inasmuch as some of his theses were deemed heretical. But Alexander VI. cleared him of the charge of heresy. He died November 17, 1494, at the early age of thirty-one. A complete edition of his works was published at Bologna in 1496; it has since been frequently reprinted. In philosophy Pico was a Neo-Platonist, though his thoughts are tinged with cabalism. Consult: Dreydorff, *Das System des Johannes Pico von Mirandola und Concordia* (Marburg, 1858); *Vita di Giovanni Pico della Mirandola, filosofo platonico* (Florence, 1882); Pater, *Studies in the History of the Renaissance* (London, 1873); also his *Life* by his nephew, translated by T. More (ib., 1890).

PICOT, pē'kō', FRANÇOIS EDOUARD (1786-1868). A French historical painter, born in Paris. He was the pupil of David and Vincent, and won the Prix de Rome in 1813. His works include: "Cupid and Psyche" (1819); "Orestes Sleeping in the Arms of Electra" (1822); an "Annunciation" (1827); and decorative paintings in the Louvre, and in Paris churches. He was awarded a first-class medal at the Salon of 1819, and the cross of the Legion of Honor in 1852. In 1836 he was elected to the Institute.

PICOT, GEORGES (1838-). A French jurist and historian. He was born in Paris, studied law, and in 1865 was appointed judge at the Seine tribunal. In 1877 he received a post in the Ministry of Justice, from which he retired when Grévy became President, to become editor of *Le Parlement*, the organ of the Left Centre. In 1878 he was elected to succeed Thiers in the Academy of Moral and Political Sciences, and in 1896 became its perpetual secretary. Among Picot's writings the chief are: *Recherches sur la mise en liberté sans caution* (1863); *Les élections aux Etats généraux dans les provinces, 1302-1614* (1874); *Histoire des Etats généraux* (1872);

2d ed. 1888), his best work, twice winner of the Gobert prize; *La réforme judiciaire* (1881); *Un devoir social et les logements d'ouvriers* (1855); *Pacification religieuse* (1892); and *Décentralisation et ses différents aspects* (1897).

PICPUS (pék'pus') **SOCIETY**. The name commonly used for a religious community in the Roman Catholic Church officially styled the Congregation of the Sacred Hearts of Jesus and Mary and of the Perpetual Adoration. It was founded in 1805 by Pierre Joseph Condrin and confirmed by Pius VII. in 1817. Its mother house is in the Rue Picpus in Paris, whence the colloquial name. The society devotes itself to missionary work, especially in Eastern Oceania and South America. Consult Keller, *Les congrégations religieuses en France* (Paris, 1880).

PICRIC ACID (from Gk. πικρός, *pikros*, bitter), or **CABAZOTIC ACID**, $C_6H_2(NO_2)_3OH$. One of the first organic dyes that have been prepared by artificial processes. It is derived from carbolic acid, or phenol, by the action of nitric acid, and is therefore called also trinitrocarbolic acid or trinitrophenol. It is best prepared by dissolving carbolic acid in strong sulphuric acid and gradually adding nitric acid; after the violent action has subsided, the mixture is kept for about two hours at a gentle heat, so as to complete the reaction. Picric acid separates out in crystalline form from the solution thus obtained, and may be purified by crystallization from hot water, in which it is moderately soluble. The acid is also formed by the action of nitric acid on many organic products, such as wool, leather, silk, indigo, resins, etc. While it is but sparingly soluble in cold water, it readily dissolves in organic liquids like ordinary alcohol, ether, benzene, etc. Its solutions have a strongly bitter taste and stain the skin as well as wool and silk a bright yellow. Formerly picric acid was much used as a dye. Since vegetable fibres are not colored by it, it may be used to detect cotton mixed in with wool. At present picric acid is used extensively for the manufacture of certain explosives. The acid itself burns quietly if ignited; but its alkali derivatives, the *picrates* of sodium, potassium, and ammonium, explode when heated, with great violence. It is mostly these derivatives of picric acid that are employed in the manufacture of explosives. The explosive known as *melinite*, however, consists mainly of the free acid. Formerly the acid was largely used in the manufacture of smokeless powder. Picric acid is said to have been employed also as a substitute for hops in the manufacture of beer. In France the acid is commonly used as a remedy for burns, as it is believed to prevent the formation of blisters. A small quantity of the acid is dissolved in a little alcohol, and the solution is diluted with a large amount of cold water; the solution is constantly applied to the burned part until the smarting pain has ceased. In organic chemistry picric acid is classed with the phenols, being a benzene derivative containing the hydroxyl group (OH). Unlike most other phenols, however, it is more strongly acid than carbonic acid, from the combinations of which (the carbonates) it is capable of taking away the alkali metals, to form picrates. These strongly acid properties of picric acid (trinitrophenol) are due to the presence of nitro-groups (NO_2) in its molecule.

PICROTOXIN (from Gk. πικρός, *pikros*, bitter + τοξικόν, *toxikon*, poison, originally that in which arrows were dipped, neu. sg. of τοξικός, *toxikos*, relating to a bow, from τόξον, *toxōn*, bow), $C_{30}H_{14}O_{12}$. The active poisonous principle contained in the seeds of *Anamirta paniculata*, which grows in the East Indies. It may be obtained from the seeds by extraction with hot alcohol and may be purified by crystallization. The substance is extremely poisonous, one-third of a grain being sufficient, when introduced into the stomach of a cat, to produce tetanic convulsions and death in a few minutes. It is sometimes used externally as a parasiticide, and internally to check night-sweating in phthisis.

PICTET, pék'tá', **RAOUL** (1842—). A Swiss physicist and chemist. He was born at Geneva and served as professor in the university of that city. He has devoted himself largely to problems involving the production of low temperatures and the liquefaction and solidification of gases. (See LIQUEFACTION OF GASES.) By using extreme cold and pressure he ascertained in 1877 that oxygen, nitrogen, and hydrogen could be liquefied, making this discovery about the same time as Cailletet (q.v.) in Paris, who employed an altogether different method. Pictet is the author of *Mémoire sur la liquéfaction de l'oxygène, la liquéfaction et la solidification de l'hydrogène et sur les théories des changements des corps* (1878); *Synthèse de la chaleur* (1879); *Nouvelles machines frigorifiques basées sur l'emploi de phénomènes physicochimiques* (1895); *Etude critique du matérialisme et du spiritualisme par la physique expérimentale* (1896); *L'acétylène* (1896); and *Le carbide* (1896).

PIC'TON, Sir **THOMAS** (1758-1815). A British general, born at Poyston, Pembrokeshire. In 1794 he went to the West Indies. He distinguished himself in the taking of Saint Lucia and Saint Vincent from the French, and Trinidad from the Spaniards, and was made military Governor of Trinidad in 1797. He restored order there, and made many improvements, and in 1801 was made brigadier-general and Civil Governor of the island. The severity of his rule caused complaint and he was superseded in 1803, but was made commandant at Tobago. He was recalled to England to answer charges against his Trinidad administration, but was honorably acquitted and as major-general (1808) went to serve at Flushing. He commanded the Third Division under Wellington, and was with him throughout the Peninsular campaigns, and fought in all the leading battles. He was promoted to the rank of lieutenant-general in 1813, joined Wellington again in the Netherlands, and was killed in the battle of Waterloo, while leading his brigade.

PICTONES, pik'tōn-ēz, or **PICTA'VI**. An ancient tribe in Gaul whose name survives in Poitiers, the capital of the Department of Vienne. They are mentioned by Cæsar with the Senones, Parisii, Carduci, Turones, Auleri, and Lemovici in the combination against the Romans organized by Vercingetorix. The chief interest in them is the belief that they were Iberians and probably blood kindred of the Picts in Scotland. On the strength of this connection and resemblance in physical characteristics, Rhys, an eminent authority, applies the title Ibero-

Pictish to the pre-Celtic longheads in Britain. In Cæsar's time the language of the Pictones was Gaulish, but originally they spoke Iberian. Consult Keane, *Man: Past and Present* (Cambridge, 1899).

PICTOU, pik-tōō'. The capital of Pictou County and a port of entry on the north coast of Nova Scotia, Canada, 84 miles north-northeast of Halifax (Map: Nova Scotia, G 4). It stands in a fertile and well-cultivated district, with extensive coal mines and quarries of building stone in the vicinity, and is the terminus of a branch of the Interecolonial Railway. It has a safe and well-equipped harbor and exports large quantities of coal, building stone, dried fish, and potatoes. An important lobster culture establishment is maintained here. The chief building is the Pictou Academy, founded in 1818. The town dates from 1763, and replaced an Indian village. The United States is represented by a consular agent. Population, in 1891, 2998; in 1901, 3235.

PICTS. An ancient people of the Stone Age (Long Barrow Period) inhabiting the whole of Great Britain. They were dolichocephalic and of rather low stature (5 feet 5 inches), dark in complexion, and are supposed to have been Iberians or, according to Sergi, longheaded Mediterraneans from Africa speaking Celtic. They were supplanted or incorporated by the succeeding Teutonic invasions in the primitive period of the English nation. The name originated from the custom of the Picts of staining or tattooing the skin. It is pretty generally agreed by scholars that the Southern Welsh, the *Firbolg* (q.v.) of Western Ireland, and perhaps the short and dark remnants in Scotland represent survivals of the Picts. The language is not only extinct, but has left no literature and only scant traces in place names. Concerning their history nothing definite is known until A.D. 297, when we find the name *Picti* used by the orator Eumenius. They called themselves *Cruithnigh* (q.v.) and occupied at that period the north and the centre of the Highlands. The Romans waged continuous war with the Picts and built large walls to keep them out of the conquered provinces. The Saxons at first did not come into contact with this race, but as they pushed farther northward they also encountered the Picts, and in 685 were defeated by their King Brude. After this a continuous border warfare was carried on with varying results. Gradually the Picts were converted to Christianity, and their King Angus MacFergus (731-761) ruled over the whole of Scotland. Soon thereafter this race disappeared as a separate entity, and in the middle of the ninth century Kenneth MacAlpine, as King of the Scots, ruled over all the different races. It must be stated that concerning nearly everything which pertains to the Picts long disputes have been carried on by scholars. Consult: Skene, *Celtic Scotland* (3 vols., Edinburgh, 1876-80); Innes, *A Critical Essay on the Ancient Inhabitants of the Northern Parts of Britain or Scotland* (Edinburgh, 1885); MacRitchie, "Modern Views of the Picts," in *The Monthly Review*, vol. ii. (London, 1901).

PICTS' HOUSES. The small stone houses built underground in Scotland probably as places of concealment during wars or other dangers, and the chambered tumuli found in the north of the British Isles, of which Mousa and Maeshow,

in the Orkneys, are types. In popular tradition they have been attributed to the Picts.

PICTURED ROCKS. A series of sandstone cliffs 300 feet in height, stretching for five miles along the shore of Lake Superior, about 45 miles east of Marquette. They present a remarkable variety of form and color, and are diversified by a number of waterfalls. The wigwam of Nokomis or Hiawatha stood on the site of Munising Harbor.

PICTURES, RESTORATION OF. See RESTORATION OF PAINTINGS.

PICTURE-WRITING. See HIEROGLYPHICS.

PICUDA, pi-kōō'dā. The largest and most voracious of the barracudas (q.v.), of which several species inhabit the American tropical seas. The great barracuda, 'picuda,' or 'becuna' (*Sphyræna picuda*) reaches a length of 6 feet, and is highly valued as food. It is silvery in color, with dark blotches along the sides, and some inky spots. Other species are known as 'piendilla,' 'guaguanche,' 'spet,' etc., and the larger ones are sometimes dangerous to bathers, attacking them as fiercely as a shark.

PICULET (diminutive of *picule*, from Lat. *picus*, woodpecker). Any one of a group of about thirty species of tropical birds, which form a subfamily (Picumminæ) of woodpeckers. They are small, plainly colored, usually marked with black, and with red or yellow on the head, and differ from typical woodpeckers in having short rounded tails without spinous shaft-tips, and the nostrils hidden by bristles. Most of them are Central and South American birds. See Plate of WOODPECKERS.

PI'CUS. A legendary king of Lavinium, father of Faunus and grandfather of Latinus. He was gifted with prophecy, a warrior and statesman. Because he aroused the jealousy of the sorceress Circe, she changed him to a woodpecker (Lat. *picus*). The whole story is late and may have arisen from a folk-tale about the bird sacred to the great god Mars.

PIDDIG, pè-dég'. A town of Northern Luzon, Philippines, in the Province of Ilocos Norte. It is situated on the Guisi River, 8 miles east of Laoag (Map: Philippine Islands, E 1). Population, 10,840.

PIDDOCK (of uncertain etymology). A bivalve mollusk of the genus *Pholas*, related to the ship-worms (q.v.). The shell is thin, white, and very hard, and beset with calcareous inequalities, connected by fine transverse parallel ridges, forming a kind of rasp, used by the animal for boring a hole, in rock, wood, or other substances in which it lives. The animal itself is club-shaped, with large, long siphons, united almost to the end, and a short foot. The shell is two or three inches in length, gaping at both ends and provided with two accessory valves. The siphons are two or three times as long as the shell and are extended to the opening of the hole in which the animal lives. Several species occur on the eastern coast of America, living buried in mud or clay. The commonest species is *Pholas truncata*, which lives in clay or peat banks between tides, and burrows into them to a depth of a foot or more. A larger and finer species is *Pholas costata*, found only in deep water. Two or three species are used in Great Britain for bait and

for food. In boring its hole, the piddock fixes itself firmly by its foot, and works itself from side to side, making use thus of the rasping power of its shell. See Colored Plate of CLAMS AND EDIBLE MUSSELS.

PIDGIN (Chinese corruption of Eng. *business*), or PIGEON ENGLISH. A mixed language much in use in the ports of China, as a medium of oral communication between foreigners who cannot speak Chinese (merchants, sea-captains, sailors, etc.) and such Chinese servants, shopkeepers, compradores, boatmen, etc., as they may have to converse with. It is also occasionally used by natives from different ports whose own dialects are so different as to be mutually unintelligible. It consists of a mixture of English words, mostly monosyllabic, with corrupted Chinese, Portuguese, Malay, and other terms and expressions, arranged according to Chinese idiom. These words are "uninflected" except to the extent that vowel-endings such as *o* or *ee* are frequently added after certain consonants which the Chinese in common with the Japanese are unable to pronounce without a following vowel; for example: *washee* for *wash*; *largee* for *large*; *s'posce* for *suppose*; *wifo* for *wife*. Owing to the inability of the Chinese to pronounce initial *r*, *l* takes its place, and 'rice' becomes *licc*; 'American' becomes *Melican*; 'friend' becomes *flew*, and 'try' becomes *tli*. Among the corrupted Chinese words are *bobbyery*, noise, disturbance, abuse, scold, either noun or verb, as "you makee too muchee bobbyery;" "howe fashion you bobbyery my?" *Chop* is a mark, brand, or device; *chop-chop* means quick! make haste! and the same *chop* occurs in *chop-sticks* or 'hasteners' used in eating. *Chow-chow* means food or eat; and *maskee* (probably of Malay or Portuguese origin), never mind! no matter! *Belong* takes the place of *be*; *my* is equivalent to I, me, my, mine ("no belong my" = I didn't do it, or it is not mine). *Sarey* means know; 'not' is replaced by *no*, and the opening sentence of Hamlet's famous soliloquy, "To be or not to be! That is the question," is simply rendered by "Can do no can do! Howe fashion?" *Joss-pidgin* means religious ceremony, and *Joss-pidgin man*, a priest, clergyman, or missionary. In the same way a tourist or sightseer becomes a 'look-see man,' and *get* is expressed by *catchee*. Consult Leutner, *Wörterbuch der englischen Volkssprache Australiens und der englischen Mischsprachen* (Halle, 1891).

PIDGIN, CHARLES FELTON (1844—). An American writer, statistician, and inventor, born in Roxbury, Mass. He received an academic education, was in the mercantile business in Boston from 1863 to 1873, and in June of the latter year became chief clerk of the Massachusetts Bureau of Statistics of Labor. Among many other machines and appliances for the mechanical tabulation of statistics, he invented an electrical adding and multiplying machine, an addition register, a self-counting tally sheet, and automatic multiple tabulating machine. He wrote the librettos for a number of musical comedies, and cantatas, and the words for more than sixty songs, and, in addition to many magazine articles, published: *Practical Statistics; or the Statistician at Work* (1888); and the novels, *Quincy Adams Sawyer and Mason's Corner Folks* (1900), and *Blennerhasset; or the Decrees of Fate* (1901).

PIEDMONT, pēd'mōnt (It. *Piemonte*, country at the foot of the mountains). A compartment of the Italian kingdom embracing the provinces of Turin, Cuneo, Alessandria, and Novara, and bounded by Switzerland, France, Liguria, and Lombardy. In 1247 a partition of the territories of Savoy (q.v.) led to the establishment of the two related lines of Savoy and Piedmont. The rulers of the second line were made princes of the Empire in the early part of the fourteenth century. In 1418 the dynasty became extinct and the land reverted to Savoy. From 1797 to 1814 it was a part of France. It constituted the principal part of the former Kingdom of Sardinia (q.v.), which was not infrequently spoken of as the Kingdom of Piedmont. See ITALY.

PIEDMONT PLAIN. A name used in the physiography of the United States to designate that part of the Atlantic coast plain which lies between the Appalachian highland and the low coastal plain proper. It is distinguished from the latter topographically by being more rugged and eroded with deeper river-valleys, and geologically by consisting of much older and harder rock strata. The change from the hard to the soft and recent formation is marked by a definite line of escarpments over which nearly all the Atlantic rivers fall in rapids or cataracts, and the line is known as the 'fall line.' The Piedmont Plain is less defined in New England than in the Southern States. It is narrowest and also approaches closest to the sea in New York, and broadens southward, being about 300 miles wide in North Carolina.

PIED PIPER OF HAMELIN, THE. A poem by Robert Browning (1842), written for a child of Maeready, the actor, on the old legend of the piper who agreed to rid the town of rats in 1284, and, because he was not paid, lured the children of Hamelin by his playing to a cave in the mountain, where they disappeared.

PIE'GAN. One of the most interesting of the Algonquian tribes in North America. They are associated with the Siksika and the Kino or Bloods in the so-called Siksika confederacy, and over two thousand of them are on the Blackfeet agency in northwestern Montana. They are well disposed and tractable, and crimes are almost unknown among them. The other members of the confederacy extend northward into Canada, where they join their co-linguists, the Creeks (q.v.), to form the westernmost tribes of the most widely diffused language family in the Western Hemisphere.

PIEHL, Pēl, KARL (1853—). A Swedish Egyptologist, born at Stockholm. He was docent in Egyptian languages at Upsala in 1881, became director of the Egyptian Museum in 1889, and in 1893 was appointed to a newly endowed chair of Egyptology. Three years afterwards Piehl became editor of the *Sphinx*, a periodical of Egyptian archaeology. His publications include: *Petites études égyptologiques* (1881); *Dictionnaire du papyrus Harris No. 1* (1882); and the great work, *Inscriptions hiéroglyphiques* (1884 sqq.).

PIENZA, pē-én'tsā. A town in the Province of Siena, Italy, 25 miles southeast of Siena. It is interesting because of the extant examples of early Renaissance architecture. The chief of

these are the cathedral, with an ecclesiastical museum attached, the *Palazzo Pubblico*, and the *Palazzo Piccolomini*. Population (commune), in 1901, 3864.

PIEPOWDER, COURTS OF (also *piepoudre*, *piepoudre*, from OF. *piepoudreux*, peddler, dusty foot, from *pie*, foot + *poudre*, powder, dust). Inferior courts in England, which formerly had special jurisdiction for the speedy trial controversies arising at fairs, markets, etc. The French name was probably applied to the court because most of the litigants were peddlers and tradesmen who traveled from one fair to another—persons with 'dusty feet.' Its jurisdiction was extended in some counties to include whole villages. This court has fallen into disuse, though it seems it has not been expressly abolished in some countries.

PIER. See BRIDGE; FOUNDATION; DOCK; WHARF; HARBOR.

PIERCE, pērs, FRANKLIN (1804-69). The fourteenth President of the United States. He was the son of Gen. Benjamin Pierce, a soldier of the Revolution and twice Governor of New Hampshire, and was born at Hillsborough, N. H., on November 23, 1804. He graduated at Bowdoin College in 1824, having among his college mates Nathaniel Hawthorne, John P. Hale, S. S. Prentiss, and Longfellow. After leaving college he studied law in the law office of United States Senator Levi Woodbury, and also in offices at Northampton, Mass., and at Amherst, N. H., and was admitted to the bar in 1827. Two years later he was elected to a seat in the State Legislature as a Democrat. He was thrice reelected and for two terms served as Speaker of the House of Representatives. In 1832 he was elected to a seat in the Lower House of Congress, and was reelected in 1834. In 1837 he was elected to the United States Senate, and when he took his seat enjoyed the distinction of being the youngest member of that body. As a member of Congress he supported by his speeches and votes the policy of President Jackson. He opposed appropriations for the Military Academy at West Point, the renewal of the United States Bank charter, and the policy of internal improvements, and was averse to the spoils system. Among his colleagues in the Senate were Benton, Clay, Calhoun, Webster, Woodbury, and Wright, in comparison with whom Pierce was not a distinguished figure, although his service was marked by industry and faithfulness to duty. In 1842, before the expiration of his term as Senator, he resigned and resumed his law practice, settling in Concord, N. H. He successively declined an appointment to fill a vacancy in the Senate, refused the nomination for Governor of New Hampshire, and would not accept the office of Attorney-General of the United States tendered by President Polk, and announced it as his fixed purpose never again to accept public office. He did not, however, cease to take interest in public affairs, and during his retirement took an active part in the councils of his party, openly advocated the annexation of Texas, and took the stump against his former college mate, John P. Hale (q.v.), the successful anti-slavery candidate for the United States Senate. Upon the outbreak of the Mexican War, Pierce promptly volunteered as a private soldier. He was soon appointed colonel, and in March, 1847, received a commission from

the President as brigadier-general of volunteers. He at once sailed for Vera Cruz and joined General Scott in time to participate in the battles of Contreras and Churubusco. In the former engagement he was thrown from his horse, but, although painfully injured, refused to leave the field. Upon the conclusion of peace he resumed his law practice, which was again interrupted in 1850 by his election as a delegate to the New Hampshire Constitutional Convention, over whose deliberations he was chosen to preside by an almost unanimous vote. At the Democratic National Convention, held at Baltimore in June, 1852, he was brought forward, after thirty-five ballottings, as a compromise candidate for the Presidency, and was nominated on the forty-ninth ballot, defeating Buchanan, Douglas, Cass, and Marey. On account of his personal popularity, and his conservative position with regard to the slavery question, General Pierce was able to draw to his support a large number of voters in the North, among them many Whigs, and consequently defeated General Scott, the Whig candidate, by a vote of 254 to 42. He carried every State except Massachusetts, Vermont, Kentucky, and Tennessee, and received a larger electoral vote than had ever before been cast for a Presidential candidate. He chose a Cabinet of able and distinguished men to aid him. This Cabinet was the only one in the history of the country that did not suffer a break during the Presidential term. The chief events of Pierce's administration were the Gadsden Purchase (q.v.), the Koszta affair (q.v.), the conclusion of commercial treaties with Great Britain and Japan, the bombardment of Greytown, Nicaragua, the reorganization of the diplomatic and consular service, and the creation of a United States court of claims. As regards the slavery question, the policy of President Pierce caused much discontent in the North. The chief events under this head were the promulgation of the Ostend Manifesto (q.v.) and the enactment of the Kansas-Nebraska Bill (q.v.), which brought on strife between the pro-slavery and free-State settlers in Kansas. From 1855 to the end of Pierce's term the sole problem of importance was that of governing Kansas and maintaining peace therein—a problem in the management of which the President did not add to his distinction. Upon the expiration of his term Pierce traveled for several years in Europe, taking no further part in politics. As an advocate at the bar, Pierce was excelled by few. Two 'campaign' biographies of Pierce were published in 1852, written by Nathaniel Hawthorne (Boston) and D. W. Bartlett (Auburn). Consult, also, Carroll, *Review of Pierce's Administration* (Boston, 1856); and Rhodes, *A History of the United States from the Compromise of 1850* (New York, 1901). See UNITED STATES.

PIERCE, GEORGE FOSTER (1811-84). A bishop of the Methodist Episcopal Church, South. He was born in Green County, Ga., the son of Lovick Pierce (q.v.). He studied law, but entered the Georgia Conference (1831). He was president of Georgia Female College, Macon, 1839-42; president of Emory College, Oxford, Ga., 1849-54; elected bishop, 1854. His sermons and addresses were edited and published by Bishop A. G. Haygood (1886). He was considered one of the ablest preachers of his Church. Consult his *Life* by George G. Smith (1888).

PIERCE, Lovick (1785-1879). A minister of the Methodist Episcopal Church, South. He was born in Halifax County, N. C.; entered the South Carolina Conference in 1805, though he began to preach the year before; he was chaplain in the army during the War of 1812; at the close of the war he retired from the ministry and studied and practiced medicine. In 1823 he reëntered the ministry and filled the chief appointments of the Church; he represented his conference in numerous general conferences. He was known as one of the most eloquent preachers of his time.

PIERIDÆ. A family of butterflies noted for mimicry. See MIMICRY.

PIERIDES, pi-ēr't-dēz (Lat., from Gk. *πριίδες*). (1) A name given the Muses from their birth-place, Pieria in Thessaly. (2) According to late mythology the nine daughters of Pierus, King of Enathlia, whom he named after the nine Muses. When they were defeated by the Muses in a musical contest, they were changed into magpies.

PIERNÉ, pyār'ná', GABRIEL (1863-). A French organist and composer, born at Metz. He was graduated at the Paris Conservatory, where he won many important prizes, including the Prix de Rome in 1882. He became organist at Sainte Clothilde in 1890, succeeding César Franck, and subsequently devoted himself largely to composition. He produced several operas (notably a four-act opera *Izél*, 1894), all of which are highly regarded.

PIERO DELLA FRANCESCA, pyār'ró dē'lá frán-chēs'ká. An Italian painter. See FRANCESCA, PIERO DELLA.

PIERO DI CASIMO, dē ká'sé-mò (1462-1521). An Italian painter of the Florentine school. He was born in Florence and was a pupil of Casimo Rosselli, from whom he derived his name and whom he assisted in painting the frescoes in the Sistine Chapel. Afterwards the influence of Leonardo da Vinci becomes apparent in his works, of which "Perseus Delivering Andromeda" (Uffizi, Florence), "Holy Family" (Dresden), "Venus with Cupid and Mars" (Berlin), "Coronation of the Virgin" (Louvre), and "Death of Procris" (National Gallery, London) are the most remarkable. A special feature of his pictures is the fine landscape backgrounds. He was the first master of Andrea del Sarto. For his biography, consult Knapp (Halle, 1899).

PIEROLA, pē'á-rō'lá, NICHOLAS DE (1839-). A Peruvian politician, born at Camaná. He was educated for the law and served as Minister of Finance during Balta's administration (1869-72). He was implicated in the revolts against Prado in 1874 and 1877, and when, in the war with Chile, Prado deserted his post, Pierola assumed the leadership of the Revolution, and was proclaimed supreme chief at Lima, in the closing days of 1879. In 1881 he was defeated and obliged to retire into the interior. Four years later he made an unsuccessful attempt to seize the Presidency, and was banished in consequence. In 1894 he headed another revolt, overthrew President Cáceres, was himself elected President in 1895, and held the office until the expiration of his term, September 10, 1899.

PIER/PONT, FRANCIS HARRISON (1814-99). An American political leader, born in Monon-

galia County, Va. (now West Virginia). He supported himself while studying and graduated at Alleghany College (Pennsylvania) in 1839. He began the practice of law at Fairmount, Va., about 1845. He was a pronounced abolitionist, and was an elector on the Whig ticket in 1848. After Virginia seceded, representatives from 40 western counties met in convention at Wheeling June 11, 1861, organized the 'Restored Government of Virginia,' and elected him Governor. He was recognized by President Lincoln and raised troops for the Federal Army. In the fall he was elected by the loyal people for the unexpired term of two years, and then for a full term of four years. When West Virginia was admitted to the Union as a separate State in June, 1863, he removed his capital to Alexandria, under the protection of the Federal Army. When Richmond was evacuated he removed there, and acted as Governor of the entire State until 1868. He then returned to Fairmount and sat in the West Virginia Legislature in 1870. President Garfield appointed him collector of internal revenue, in which capacity he served until the consolidation of his district.

PIERPONT, JOHN (1785-1866). An American poet. He was born in Litchfield, Conn., April 6, 1785, and graduated from Yale College in 1804, after which he taught school for a few years. He then studied law and practiced at Newburyport, Mass. After unsuccessful business ventures in Boston and Baltimore, he studied theology in the Harvard Divinity School, and in 1819 was ordained over the Hollis Street Congregational (Unitarian) Church in Boston. His advocacy of anti-slavery, temperance, and other reforms caused his withdrawal from that parish in 1845, after which he became pastor of the Unitarian Church at Troy, N. Y., and of the First Church (Unitarian) at Medford, Mass. During the Civil War he was appointed, though seventy-six years old, as chaplain of a Massachusetts regiment, but was soon transferred to the United States Treasury Department, where he remained till his death at Medford, Mass., August 26, 1866. He published, among other volumes: *Airs of Palestine* (1816; republished and enlarged as *Airs of Palestine, and Other Poems* in 1840) and *Anti-Slavery Poems* (1843). Some lines on his dead son are also notable for their pathos. He was a genuine poet, though his work is rather slight.

PIERRE, pēr. A city, the county-seat of Hughes County and the capital of South Dakota; situated near the centre of the State, on the Missouri River, and on the Chicago and Northwestern Railroad (Map: South Dakota, E 5). It has a Government industrial school for Indians, and is the commercial metropolis of an extensive stock-raising and farming district. It is the largest stock market in the State, the annual shipments of cattle averaging 1000 cars. Underlying the city are supplies of natural gas, which is used for lighting and heating and for industrial purposes. Pierre was settled in 1880, and incorporated three years later. It is governed under a charter of 1900, which provides for a mayor, elected biennially, and a council. The water-works, gas plant, and electric light plant are owned by the municipality. Population, in 1890, 3233; in 1900, 2306.

PIERREPONT, pēr'pōnt, EDWARDS (1817-92). An American lawyer and diplomat, born at

North Haven, Conn. He graduated at Yale in 1837, was admitted to the bar in 1840, and practiced at Columbus, Ohio, until 1845, when he removed to New York. He was elected judge of the Superior Court, New York, in 1857, but resigned in 1860, and resumed his practice. In 1867 he conducted the case for the Government against John H. Surratt, indicted as an accomplice in the murder of President Lincoln, and in 1869 he was appointed United States District Attorney by President Grant, but resigned a year later, when he took an active part as one of the Committee of Seventy in fighting the Tweed ring. He was appointed Attorney-General of the United States in 1875, and the next year Minister to the Court of Saint James's, which post he resigned in 1877. During his later years he took a keen interest in finance, and published several pamphlets dealing with financial questions.

PIERROT, pyá'ró'. A character of French comedy taken over from the Italian Pedrolino of the *commedia dell' arte*. Toward the beginning of the eighteenth century he appeared on the French stage in parodies at the Opéra Comique and other theatres. The Pierrot of the pantomime was introduced by Debureau at the Funambules, and reappeared with the revival of the pantomime at the end of the nineteenth century. Pierrot's costume consists of very wide trousers, a loose coat with great buttons, and a wide collar, all white.

PIERSON, pēr'son, ABRAHAM (c.1645-1707). An American educator. He was born probably at Southampton, Long Island, N. Y., graduated at Harvard in 1668, became colleague pastor with his father at Newark in 1672, and was in sole charge of the New Church from 1678 to 1692. He then preached for two years in Greenwich, Conn., became pastor at Killingworth, Conn., in 1694, and from 1701 until his death was the first president, or rector, of Yale College. See YALE UNIVERSITY.

PIERSON, ARTHUR TAPPAN (1837—). An American Presbyterian minister, born in New York City. He graduated at Hamilton College in 1857, was pastor of Congregational churches at West Winsted, Conn., in 1859-60, at Binghamton, N. Y., in 1860-63, and at Norwalk, Conn., in 1863. In the latter year he became a Presbyterian; thereafter had charge of churches of that denomination at Waterford, N. Y. (1863-69), Detroit, Mich. (1869-82), Indianapolis (1882-83), and Philadelphia (1883-91). He occupied the pulpit in the Metropolitan Tabernacle, London, in 1891-93. He was made editor of *The Missionary Review of the World* when it was founded in 1888. His publications include: *Many Infallible Proofs* (1886); *Crisis of Missions* (1886); *Divine Enterprise of Missions* (1891); *Miracles of Missions* (1891); and *New Acts of the Apostles* (1894).

PIERSON, HENRY HUGO (1815-73). An English musician and composer, born at Oxford. His correct name was Henry Hugh Pearson. He was educated at Harrow and Cambridge, and before his graduation (1830) had set to music half a dozen of Byron's songs. Forsaking the study of medicine for that of music, he went to Germany (1839), where he became a pupil of Reissiger, Tomaschek, and Rinck, the organist.

He returned to Great Britain (1844) to be Reid professor of music in Edinburgh University, but shortly went back to make his home in Germany, where the greater number of his works were produced, though the best of them, the oratorio *Jerusalem*, was first sung at the Norwich Festival of 1852. Two years afterwards he received the gold medal of art and science from the Belgian King for his musical setting to *Faust* (part ii.), while his five-act opera *Contarini* was performed at Hamburg the year before his death, which occurred in his Leipzig home. Besides his first operas, *Der Elfensieg* (Brünn, 1845) and *Leila* (Hamburg, 1848), he left an unfinished oratorio, called *Hezekiah*, and several fine overtures, songs, and choruses, sacred and secular, of which only *Ye Mariners of England* gained favor in his native land.

PIERS PLOWMAN. See LANGLAND, WILLIAM.

PIERS PLOWMAN'S CREDE. An alliterative poem, written about 1394 by an unknown poet whom Skeat identifies with the author of the *Plowman's Tale*. An ignorant man, wanting to learn his creed, applies to friars for help. They merely show their greed and jealousy of one another, and the creed is taught at last by a poor plowman.

PIETAS (Lat., piety). In Roman mythology, the goddess of loyalty, especially of filial devotion. She is symbolized by the stork.

PIETER DE KEMPENEER, pē'tēr de kēm'-pe-nār. The name of the Flemish-Spanish painter Pedro Campaña (q.v.).

PIETERMARITZBURG, pē'tēr-mā'rīts-bōrg. The capital of the British colony of Natal, South Africa, 40 miles by rail, northwest of Durban, the chief port of the colony (Map: Africa, H 7). It is a well-built town, situated 2200 feet above sea-level, and is noted for its healthful climate. It has considerable trade, and is the seat of an Anglican bishop. Its chief features are the Government buildings, town hall, a fine park, botanical gardens, and bathing establishments; it has electric lighting. The town was founded by the Boers in 1839, and named after the two Boer leaders Pieter Retief and Geert Maritz. Population, in 1901, 30,000.

PIETISM (from piety. OF. *piete*, Fr. *piété*, from Lat. *pietas*, piety, from *pius*, pious). A name given in the latter part of the seventeenth century to a religious movement in Germany, distinguished by certain peculiarities of religious opinion and the manner in which these were manifested. The name is also applied to similar tendencies of opinion, feeling, and conduct exhibited elsewhere. Pietism may be regarded as an exaltation of the importance of religious feeling and of the practical part of religion, with a corresponding depreciation of doctrinal differences, and a contempt for outward ecclesiastical arrangements.

German Pietism was the natural outcome of conditions existing in the seventeenth century. The Reformers had emphasized the efficacy of faith in Christ as the means of securing deliverance from sin. But the controversies which arose among them and increased among their successors gradually gave a too exclusively doctrinal and polemical character to the sermons and writings of both Lutheran and Calvinistic

divines. When the inevitable reaction came it took form in favor of a religion of feeling and good works, or of the heart and life. Johann Arndt (1555-1621), Johann Valentin Andreæ (1586-1654), both Lutherans, and Johannes Coecejus (1603-69), a Calvinist, may be regarded as forerunners of Pietism. But its full development is to be ascribed to Peter Jakob Spener (q.v.) and his friends and disciples, particularly the Leipzig Doceats, Paul Anton, J. K. Schade, and August Hermann Francke. Driven from Leipzig by the opposition of the older school of theologians, Francke and Anton found a refuge, through Spener's influence, in the newly founded University of Halle, and under their lead and that of their associates, Joachim Justus Breithaupt and Hermann Lange, Halle became the centre of the movement and a source of new religious life in Germany. Pietism also became dominant in the universities of Königsberg, Giessen, and Marburg, and from North Germany spread to the south, where its head was Johann Albrecht Bengel, and even to other lands. Ultimately it went to excess, fantastic doctrines and fanatical practices came to prevail, and the rationalism of the eighteenth century was the inevitable and healthful reaction. For further details, see the article GERMAN THEOLOGY, section *The Period of Pietism*; see also the biographical notices of Spener, Francke, Bengel, and the other leaders. Histories of Pietism have been written by Schmidt (Nördlingen, 1863); Tholuek (Berlin, 1865); Heppé, treating particularly of the movement in the Netherlands (Leipzig, 1870); and Ritschl (Bonn, 1880-86). Consult, also, Renner, *Lebensbilder aus der Pietistenzeit* (Bremen, 1886); Hubener, *Pietismus geschichtlich und dogmatisch geschildert* (Zwickau, 1901).

PIET PAALTJENS, pēt pält'yēns. The pseudonym of the Dutch poet Francis Haverschmidt (q.v.).

PIETRA-DURA, pyā'trā dōw'rā (It., hard stone). A name given to the finest kinds of Florentine mosaic-work, in which the inlaid materials are hard stones, such as jasper, carnelian, amethyst, agate, etc. The real pietra-dura work dates as far back as the sixteenth century, about 1570; and from that time to the present has been almost confined to Florence, where a Government atelier has existed ever since the beginning of the seventeenth century. In the inferior kinds, which are sold in Italy, and are also manufactured in Derbyshire and other parts of Britain, pieces of colored sea-shells are used instead of the harder and more valuable colored stones.

PIETRAPERZIA, pyā'trā-pēr'tsē-ā. A town in the Province of Caltanissetta, Sicily, seven miles southeast of Caltanissetta. It has an old Norman fortress, and carries on a trade in grain and almonds. There are sulphur and gypsum mines in the vicinity. Population (commune), in 1881, 11,284; in 1901, 12,826.

PIETRASANTA, pyā'trā-sān'tā. A town in the Province of Lucca, Italy, 15 miles northwest of Lucca by rail, and two miles from the Mediterranean. It is situated on a hill, on the top of which is a large fortress, and is surrounded by a wall. The fourteenth-century Church of San Martino has fine choir stalls and a baptistry with bronze decorations by Donatello. The surrounding country is fertile, and the grape and

olive are produced in abundance. There are marble quarries and quicksilver mines. Population (commune), in 1881, 14,382; in 1901, 17,444.

PIETSCHMANN, pēch'mān, RICHARD (1851—). A German Orientalist. He was born at Stettin, studied in Berlin and Leipzig, and in 1888 became university librarian at Göttingen, where two years afterwards he received an appointment to a chair of Egyptology and Oriental history. He wrote: *Hermes Trismegistos* (1875); *Geschichte der Phönizier* (1889); and translations of Maspero's Oriental history (1877), and of the part dealing with Egypt in Perrot and Chipiez, *Histoire de l'art dans l'antiquité* (1884).

PIEZOMETER (from Gk. πῆζειν, *piezein*, to press + μέτρον, *metron*, measure). An instrument for measuring the compressibility of fluids. The name was given by Oersted (q.v.) to a piece of apparatus which he devised in 1822, and with which he was able to determine the compressibility of water, mercury, alcohol, and other liquids. It consisted of a cylinder of thick glass closed at either end by a brass cap. A tube of glass or brass containing a piston or a screw plug was fitted to the upper cap, by means of which considerable pressure could be exerted on the liquid in the cylinder below. This cylinder was sufficiently large to contain a glass flask whose neck was drawn out into a fine tube, like that of a thermometer, graduated into equal divisions, each of which represented a certain fraction of the volume of the flask. The flask was filled with the liquid whose compressibility was to be determined, and a small thread of mercury introduced into the fine tube. It was then placed inverted in the cylinder, which was filled with water, being so supported that the end of the fine tube dipped into a small vessel of mercury at the bottom. In this was placed another tube closed at its upper end, which acted as a manometer, enabling the observer to measure the pressure sustained by the liquid by the height of the mercury column. When the piston was pushed or screwed down, the liquid in the cylinder was put under pressure. This pressure was communicated to the liquid in the flask, which was compressed by a small amount, as was shown by the use of the mercury in the fine tube. Knowing the volume of the flask and the value of the divisions of the tube, the amount of compressibility was readily ascertained by the pressure shown by the manometer, and in this way Oersted found that the compressibility of water for one atmosphere of pressure amounted to 46.65 millionths. Colladon and Sturm, who performed a series of similar experiments, made this value 49.65 millionths, while Grassi somewhat later fixed the compressibility of water at 0° centigrade at 50 millionths, and at 53° centigrade at 44 millionths. With the piezometer it was also demonstrated that liquids are perfectly elastic, since when the pressure is removed the mercury sinks to its former position, showing that the liquid returns to its original volume.

PIFFERARI, pif'fā-rā'rē (It., pipers). The name given to shepherds of the Abruzzi who formerly flocked to Rome in the Advent season and collected gifts at the shrines of the Virgin, where they sang and played old airs on pipes and bagpipes. The pifferari were among the picturesque features of Rome and usually went in

pairs, an old man with pointed hat, cloak, sandals, and bagpipe, accompanied by a boy clothed in a skin and carrying the pipe.

FIG. See HOG; SWINE.

PIGAFETTA, pè'gà-fèt'tà, (FRANCESCO) ANTONIO (1491-c.1534). An Italian traveler and historian, born at Vicenza. His first journey was to Spain, where he obtained leave to go on the Magellan expedition (1519-22), and Pigafetta's was the chief account of the voyage. It was printed in French and Italian at Milan (1800), and a later edition came out in Rome under the title *Relazione intorno al primo viaggio di circumnavigazione. Notizie del Mondo Nuovo con le figure de' paesi scoperti* (1894).

PIGALLE, pé'gál', JEAN BAPTISTE (1714-85). A French sculptor, born in Paris. He was a pupil of Robert Le Lorrain and Lemoyne, and then studied in Rome. In 1741 he was elected to the Academy, where he became professor in 1752 and rector in 1777. His "Mercury Fastening His Sandals" (1763), a "Child with Cage," the busts of Marshal Maurice of Saxony (1750) and of the surgeon Guérin, and the marble statue of the Duke of Richelieu are in the Louvre. Other works by him include a marble group of the "Queen of Heaven," in Saint Sulpice, Paris; the tomb of the Comte d'Harcourt—partly destroyed, but restored—in Notre Dame, Paris; a statue of Voltaire in the library of the Institute; and his masterpiece, the tomb of Marshal Maurice of Saxony, in the Church of Saint Thomas at Strassburg. Consult Tarbé, *La vie et les œuvres de J. B. Pigalle* (Rheims, 1859).

PIGEON (OF. *pigeon*, *pipion*, Fr. *pigeon*, It. *piccione*, *pippione*, pigeon, from Lat. *pipio*, squab, young bird, from *pipire*, to chirp, onomatopoeic in origin). A name applied, like dove (q.v.), to all members of the family Columbidae. Although members of the group differ greatly in size and color, with a few exceptions they are easily recognized. They are chiefly medium-sized or rather large birds. Most of those of temperate regions are plainly colored with gray, brown, or slate, and some black and white, but some of the tropical forms show brighter shades of blue and purple; while the fruit-pigeons of the far Orient are gorgeous in green, yellow, orange, red, violet, and blue. The wings are usually long and pointed; the tail more or less elongated. The crop is large and double; during the breeding season it becomes glandular and secretes a milky fluid upon which the young are in part fed, or at any rate it moistens the food given them by their parents. The plumage of pigeons is generally very dense, quite smooth, often reflecting metallic lustres; the feathers entirely lack the aftershaft. Pigeons are monogamous, and the birds seem much attached to each other, and share mutually the labors of nest-building, incubating, and caring for the young. The nests are always flimsy structures of a few twigs in a tree, and the eggs, almost always two in number, are pure white. The young are naked and helpless when hatched. Pigeons are vegetarians, and eat fruit, grain, seeds, and the like, and are therefore often destructive in cultivated fields. Their notes are soft, low, and rhythmic—well described as 'cooing.' The flesh of most species is good eating, and they are ranked game-birds and are much

hunted. The flesh is nutritious, and that of the young, or 'squabs,' from twenty to twenty-five days old, is particularly delicate, and in some parts of the United States great numbers of domesticated doves are reared for market. One establishment near Los Angeles, Cal., kept in 1901 more than 10,000 to supply the demand for this delicacy.

More than 300 species of pigeon are known, of which nearly or quite half are the so-called fruit-pigeons of the East. The geographical distribution of the pigeons, living and extinct, suggests some of the most interesting inquiries in zoölogy. One interesting fact is that pigeons are generally absent from regions where monkeys abound, as these nimble thieves rob their open, unprotected nests so persistently that the two races of animals cannot dwell in the same district. Twelve species have been taken within the boundaries of the United States, but eight of these are West Indian or Mexican species, found only occasionally along our southern boundary. The remaining four are the little ground-dove (q.v.); the common 'mourning' or Carolina dove (*Zenaidura macroura*), abundant throughout temperate North America; the band-tailed pigeon (*Columba fasciata*), a large stout species, with a noticeable black bar across the bluish-ash tail, common from the Rocky Mountains to the Pacific; and the formerly very numerous 'wild' or 'passenger' pigeon.

The North American wild pigeon (*Ectopistes migratorius*) is especially interesting from the marvelous numbers composing its flocks before the settlement of the interior of the country caused its almost total disappearance. It is a large, slender bird, with a small head, notched beak, turned at the base, short strong legs with naked feet, a long acuminate tail, and very long, pointed and powerful wings. It is a beautiful bird, of very graceful form and finely colored plumage, and formerly was found in almost all parts of North America. It is not, properly speaking, a bird of passage, as apparently its movements are consequent on the failure of a supply of food in one locality and the necessity of seeking it in another. Its power of flight is very great. The nest of the passenger pigeon consists of a few dry twigs placed in a fork of the branches of a forest tree, and contains two eggs. They breed two or three times in a season. Although both the bird and its nest are rarities now, only isolated colonies remaining in the less settled parts of the country. During the early part of the nineteenth century incredible numbers of pigeons were wont to roost at night and nestle in certain breeding-places in the forests of the Mississippi Valley, where sometimes 100 or more nests were often seen in a single tree. These great breeding-places extended over a tract of forest, sometimes not less than forty miles in length. Flocks of pigeons were often seen flying at a great height in dense columns, eight or ten miles long; and calculations made by careful observers agreed that in some of their great migrations the column, a mile broad, was more than 150 miles long. The roosting-places were correspondingly extensive. The noise of wings and of cooing voices drowned the report of guns. The multitudes which settled on trees broke down great branches by their weight, so that it was dangerous to pass beneath. They crowded together, alighting one upon another, till they formed solid masses like hogs-

heads, and great numbers were killed by the breaking of branches. The inhabitants of the neighboring country would assemble, shoot them, knock them down with poles, stifle them by means of pots of burning sulphur, cut down trees in order to bring them in great numbers to the ground, eat them fresh, salt them, and bring hogs to fatten on them. Wolves, foxes, lynxes, cougars, bears, raccoons, opossums, polecats, eagles, hawks, and vultures congregated to share the spoils.

Such are the facts given by Wilson, Audubon, and the early historians of the West, and abundantly verified. The disappearance of these birds, as soon as settlers began to invade and clear away the woods, was so rapid as properly to be called sudden; and it is not easily explained.

Of the pigeons of the Old World, the most interesting is doubtless the blue rock pigeon, or rock dove (*Columba livia*), the 'biset' of the French, a bird of extensive geographical range. It is found as far north as the Farøe Islands and over the greater part of Europe, and breeds in crevices of rocks and often within caverns which open on the sea. In a wild state this bird exhibits great uniformity both in size and plumage; the prevailing color is bluish-gray, with two distinct bars of black across the closed wings. It is commonly believed that domestic pigeons are all descended from this species, although possibly some were derived from the very similar *Columba intermedia*. The ordinary domestic pigeon differs from the wild chiefly in color, and a tendency to revert to the original coloring has been observed. There are 250 or more domestic breeds, and they have undergone many remarkable changes under the selective care taken by intelligent fanciers, who often pay very high prices for fine birds. Some of the varieties which exhibit very strange peculiarities are known as 'fancy' pigeons, and are carefully tended and preserved by pigeon-fanciers. Of these may be mentioned, as among the most interesting, the rough-footed pigeon, having the feet feathered; the Jacobin, which has a range of feathers inverted over the head, and extending down each side on the neck, as a hood; the fan-tail, in which the number of the tail feathers is greatly increased, and the bird has the power of erecting its tail like that of a turkey-cock; the tumbler, so called from turning somersaults in the air in its flight, and further characterized by a very short bill; the pouter or 'cropper,' which has the power of blowing up its crop to an extraordinary degree so that the head seems fastened on the top of an inflated bladder; and the black nun.

None of these have the popular interest and value, however, reached by the carrier, or 'homing' breed, which is trained to return to its home from great distances, and is utilized for carrying messages in places where, sometimes, no other means of communication is available. This represents the highest example of pigeon development. This breed is of large size, about 15 inches long, and has the cere very large and carunculated, the eyes surrounded with a broad circle of naked red skin, and the wings reaching nearly to the extremity of the tail. Carrier pigeons are trained by being conveyed, when young, to short distances of a few miles from home and then let loose, the distance being grad-

ually increased until at last as much as 100 miles may be added, and the pigeon made to return accurately and swiftly from 500 to 600 miles away. Pigeons intended for this use must be brought from the place to which they are to return within a short period (not exceeding a fortnight) of their being let loose, and at a time when they have young in their nest; the remarkable fecundity affording particular facilities for its employment in this way. The impulse of the bird is to return to its family with the utmost haste.

The use of carrier pigeons is very ancient in the Orient, and was brought to the attention of Europe at the time of the First Crusade, when the Saracens were found to have the birds in regular use for the conveyance of information; and the Christian commanders employed falcons to chase and intercept this pigeon-post on several occasions, and on others caught the tired birds, substituted misleading messages for those they were carrying, and sent them on to deceive the enemy. Arabic writers attribute to the perfection of a system of pigeon-posts elaborated by the great Turkish sovereign Nur-ed-din a large part of his success in welding together the scattered parts of his broad empire. Although their use, publicly and as an amusement, continued, it was not until the Franco-Prussian War of 1870 that pigeons were again of conspicuous public service. During the siege of Paris constant communication between the beleaguered city and the outside world was obtained by this means, microphotographs of military despatches, private letters, and even newspapers, being printed upon films of collodion and carried by the birds—as much as 30,000 words in some instances. These would then be enlarged by photography and made legible. Subsequently the German, French, and other European governments established regular pigeon-corps in the intelligence departments of their armies and navies, and thousands of birds were trained, and many continue to be kept for use as messengers. Experiments were tried extensively by the French in the employment of pigeons at sea. It was found that they bore voyages well, and would fly from a distance of over 300 miles to shore-stations with great accuracy; but that they could not be depended upon to go from ship to ship. In 1897 many trials were made in the United States Navy, especially by Admiral Sieard, and considerable success was attained. A similar news-service was also attempted by certain newspapers in coöperation with some of the Atlantic steamship companies, but was not long maintained.

The flight of one of these birds is steady, direct, and rapid, but the rate of speed has been exaggerated, and is now known to be on the average only about 30 miles an hour and rarely 45 miles. It begins with a spiral flight upward as soon as the bird is released from its confinement (usually in a portable dark basket), which is continued to a sufficient height to enable the bird, searching the horizon, to catch sight of some landmark with which it has previously been made familiar. Its memory in this respect is marvelous; and it may be assisted by that instinctive faculty for direction which seems innate in many birds and other wild animals. (See MIGRATION.) It then directs its course straight toward that point, when it will sight

PIGEONS

1. WILD or PASSENGER PIGEON (*Ectopistes migratorius*). 2. EUROPEAN TURTLE-DOVE (*Turtur communis*). 3. GROUND-DOVE (*Columbigallina passerina*). 4. TOOTH-BILLED PIGEON (*Didunculus strigirostris*). 5. BLUE ROCK PIGEON (*Columba livia*). 6. CRESTED BRONZEWING (*Ocyphaps lophotes*). 7. CROWNED PIGEON (*Goura coronata*).

another landmark and so proceed from known place to place until it reaches home. Many societies in various parts of the world are breeding these pigeons and perfecting their abilities, and 500-mile races are frequently run.

The pigeons are a family, Columbidae, of the charadriiform suborder Columbæ, which also includes the families Dididae (see DODO) and Didunculidae (or tooth-billed pigeons). The Columbidae are divided by structural features into several subfamilies: (1) Gourinae, containing the gouras (q.v.). (2) Peristerinae, containing such tropical groups as the Nicobar pigeon, the wonga wonga of Australia, the bronze-wings, and several other robust, often terrestrial forms of the East and West Indies; also the ground-doves of American warm latitudes; the scaly doves of the Andean region; the American mourning-doves, and the many species of turtle-doves (q.v.) of the Old World. (3) Columbinae, the typical pigeons. (4) Treroninae, the fruit-pigeons, in the widest sense, about 120 species, most of which are Oriental and African.

BIBLIOGRAPHY. Excellent popular accounts of pigeons in general will be found in the *Standard and the Royal Natural Histories*; by Evans in *Birds* (New York, 1900); and by Newton, in *Dictionary of Birds* (New York, 1896), the latter with many bibliographical references. Monographs have been prepared by Temminck (1808-11), Prevost (1838-43), and Selby (1835), but the most recent is Salvadori's vol. xxi. (London, 1893) of the *Catalogue of Birds in the British Museum*. In respect to domestic pigeons, many works exist, of which the foremost is Tegetmeier, *Pigeons, Their Structure, etc.* (London, 1867); Darwin, *Origin of Species* (London, 6th ed., 1882); id., *Variation of Animals and Plants* (London, 2d ed., 1875); Helm, *Cultivated Plants and Domestic Animals* (English trans. by Stallibrass, London, 1891); Rice, *The National Standard Squab Book* (Boston, 1902); id., *Robinson's Method of Breeding Squabs* (ib., 1902).

PIGEON-BERRY. The fruit of a perennial herb. See POKE; PHYTOLACCA.

PIGEON-ENGLISH. See PIDGIN-ENGLISH.

PIGEON-FLYING. The art and practice of training and coursing carrier pigeons, according to the rules of societies which exist for the promotion of competitive races. See PIGEON.

PIGEON-HAWK. A falcon (*Falco*, or *Falco columbarius*), inhabiting the cold and temperate parts of America. It is from twelve to fourteen inches in length, with a spread of wing, in the female, of from two feet to twenty-six inches. The male, as is usual with falcons, is smaller. In the adult the back is of a bluish slate color, every feather having a longitudinal black line. The throat, breast and belly are pale pinkish or yellowish white, each feather with a longitudinal line of very dark brown. The quills are black, with ashy white tips; bill blue, legs reddish yellow, with dark lines. It is the most fierce of all hawks in proportion to its size, and lives mainly upon small birds, such as pigeons, but rarely if ever attacks poultry. It breeds in the northern part of the continent, but passes the winter in the tropics. A familiar hawk of India, known to falconers there as 'turumti' (*Falco typlus*), and an Ethiopian species (*Falco*

ruficollis) complete this lively and interesting genus. Consult American and European ornithologies, especially Fisher, *Hawks and Owls of the United States* (Washington, 1893).

PIGEON-PEA (*Cajanus*). A genus of plants of the natural order Leguminosæ, of which there is only one species (*Cajanus indicus*), a native of the East Indies, but much cultivated also in the West Indies and in Africa, where, as in other tropical countries, the plants annually drop their leaves and reproduce new ones with their flowers, when they are productive for several years. The seeds are among the most valuable tropical kinds of pulse. The plant is a shrub attaining a height of four to ten feet when grown in favorable regions, although in cultivation it is generally treated as an annual. It grows either in rich or poor soils. Tested at the Louisiana Experiment Station, the pigeon-pea was found very susceptible to frost and not well adapted to growing in this country.

PIGEON-PLUM. A Florida fruit. See SEASIDE GRAPE.

PIGLHEIN, pig'hin, BRUNO (1848-94). A German painter, born at Hamburg, where he originally studied sculpture under Lippelt. Subsequently a pupil of Schilling in Dresden, he was influenced by a visit to Italy to take up painting under Pauwels at Weimar (1870), then studied under Diez in Munich and after some decorative work became more widely known through his religious composition "Moritur in Deo" (1879, National Gallery, Berlin), representing Christ on the cross kissed by the Angel of Death. Soon afterwards he began to cultivate the pastel almost exclusively, and depicted fashionable ladies, roués, masked figures and dancers, but also executed many refined portraits of women and children, and scenes from child life, of which the "Idyl" (child and dog snugly seated by the water) became widely familiar through reproductions. After 1886 he gave preference again to religious subjects, well exemplified by an "Entombment" (1888), in the New Pinakothek at Munich, which also contains the impressive "Blind Maiden Going to the Well" (1890).

PIGMENT. See PAINTS.

PIGMENT (Lat. *pigmentum*, from *pingere*, to paint; connected with Skt. *piś*, to adorn). In animals, the coloring granular matter in certain cells of the inner layer ('derma' of vertebrates, 'hypoderma' of arthropods) of the skin. In mammals and man the pigment is brown or nearly black, that of the retina of the eye very black and abundant, and is always situated in cells of the Malpighian layer, which lies between the epidermis and derma; in amphibians the pigment is accumulated mostly in the derma, partly diffused, and partly inclosed within the cells. In birds, the skin being very thin and concealed by the feathers, the coloring matter is mainly confined to the feathers. The principal pigments are: Zoömelanin, the black animal coloring matter, distributed in amorphous little corpuscles, insoluble in water, alcohol, acid, or ether, but dissolved and destroyed when boiled in caustic potash and then treated with chlorine; it consists of about 53.5 per cent. of carbon, 4.6 of hydrogen, 8.2 of nitrogen, and 32.7 of oxygen. Zoöerythrin, red, hitherto found in the red feathers of cotinga, the flamingo, ibis, a cockatoo, the car-

dinal-bird, and others, and in the 'rose' around the eyes of the grouse. It is soluble in ether, alcohol, and chloroform, but not in acids or in potash. Zoöxanthin, yellow, can be extracted by boiling in absolute alcohol, and is a diffused pigment which tinges the shafts, rami, and radii of the feathers, and is possibly the same in the yellow feet and bills of birds of prey and ducks; like zoërythrin, it is a colored fatty oil. Turacin is a most peculiar pigment, detected in the red feathers of the Musophagide, and seems to be restricted to these birds. It consists of the same elements as zoömelanin with the addition of from 5 to 8 per cent. of copper. Such pigments appear in the coloring matter of birds' eggs. See Egg.

In insects the conditions are somewhat different, as the coloring matter is lodged not only in the scales, but in the skin or crust of the body. The pigment in most insects, as well as in the lobster, is secreted in the deeper layer of the skin, under the cuticle, and this layer is called the hypodermis. When the lobster casts its shell the soft hypodermal layer consists of cells which are filled with red and blue pigment masses. This cellular layer gives rise to the outer cuticle, which thus derives its hue, red and blue, from the deeper inner layer of color-secreting cells. In most insects the cuticle is nearly colorless, or horn-colored or honey-yellowish, in tint.

It has been found by experiments that pigments may be dissolved out by chemical reagents and subsequently restored by other agents. Both Coste and Urech have proved that red, yellow, brown, and black colors in the scales of certain butterflies are always due to pigments, and in a few cases greens, blues, violets, purples, and whites are due to the presence of pigments in the scales themselves. Dr. A. G. Mayer believes that the pigments of lepidopterous insects are derived from the blood of the chrysalis. The first color to appear in the pupa or chrysalis of the American silkworm, on which he made his observations, is dull-yellow ochre or drab; this is of the hue of the blood when removed from the chrysalis and exposed to the air. Mayer has also artificially produced several kinds of pigments from the blood, which are similar in color to various markings on the wings of the imago, or adult. He has also found that chemical reagents have the same effects on these manufactured products as on similar pigments in the wings of the living moth.

As regards pigmental colors, Baer classified them into two types: diffused and granular. Pigments of the first type are diffused through the chitin or substance of the scale, are usually present in very small amount, and include the dark pigments, most yellows, oranges, and reds, except in the Pieridæ, and the whites (uric acid) of the Pieridæ. Baer also, contrary to the results of Hopkins, found that some of the orange and yellow pigments of the Pieridæ are diffuse and not granular. Granular pigments occur exclusively in the Pieridæ and are yellow or red in color. They color the scales in which they occur very deeply. Such scales are few in number and almost without surface sculpturing. The superposition of dark-colored scales upon scales deeply tinted by yellow granular pigment may, as in *Anthochaus cardamines*, produce a greenish tint.

Equal activity has been shown by chemic-

biologists in the study of the coloring matter of flowers. It is now held that nearly all blue and red pigments originate from tannin; in other words, tannin constitutes the chromogen of the red and blue floral pigments. Keegan showed that the circumstances which created or influenced the particular tint of flowers was first chemical (the presence of quercetin in the form of rutin, etc., in the corolla), and second, physiological, i.e. the possession by the corolla of energetic respiratory and transpiratory functions, with the result that the substances contained in its cells underwent an oxidation more or less vigorous and complete.

PIGMY PARROT. One of the diminutive parrots of New Guinea, of the subfamily Nasiternine, which are smaller than a song sparrow. They have beaks like those of miniature cockatoos, short square tails, and the males have gorgeous plumage, but the females are more soberly dressed.

PIGNEROL, pé'nye-rôl'. The French name of the town of Pinerolo (q.v.), in Italy.

PIGNUS (Lat., pledge). At Roman law, a pledge, i.e. something given to secure performance of an obligation. Originally, *pignus* could be established only in corporal things, and only by giving possession; and it conferred no right upon the pledgee except that of retaining possession until the debt was paid. Power of sale in case of the debtor's default was first introduced by contract, but eventually the power of sale became part of the general law of pledge. Pledge of a claim against a third person (*pignus nominis*) was also recognized, a quasi-possession of the pledgee being established by notice to the pledgor's debtor. Before the close of the republican period the pledge of a thing had become independent of possession; it could be established by mere agreement; and such a contractual lien was enforceable against third persons. With this change *pignus* and hypotheca (see HYPOTHECATION) became virtually the same thing. In the Justinian law *pignus* designates a pledge or mortgage of movable property or of a debt, while hypotheca designates a mortgage of immovable property.

From the point of view of the relation of pledgor and pledgee, *pignus* was regarded as one of the real contracts. See CONTRACT.

Pignus could be established not only by contract, but by will. It could also be established by levy on property in execution of judgment, and it was established in some cases by direct operation of law, as in the case of the landlord's lien on the effects brought in by the tenant.

Modern civil law recognizes as a rule no pledge of movables without possession. See PROPERTY; also BAILMENT.

PIGNOT. See EARTHNUT.

PIGOTT, pig'ot, RICHARD (1828?-89). An Irish journalist and forger. He passed a checkered career on several Dublin newspapers. In 1879 he was proprietor of three newspapers, which he soon sold to the Irish Land League, of which Charles Stewart Parnell (q.v.) was president. Hitherto a violent Nationalist, Pigott now began to vilify his former associates and to sell information to their political opponents. His famous transaction was with the Irish Loyal and

Patriotic Association, founded in 1886, to resist home rule for Ireland. His papers, part true and part forged, furnished to this organization, were purchased by the London *Times*, in which they began to appear under the heading "Parnellism and Crime" (1887). Widespread sensation was created by a letter (published April 18, 1887), purported to be signed by Parnell. In this letter sympathy was expressed for the Phoenix Park murderers. In 1888 Parliament appointed a commission to inquire into the charges made by the *Times* against the Irish leader. Pigott was exposed by Sir Charles Russell, the counsel for Parnell, confessed his crime to Henry Labouchère, and fled to Madrid, where he shot himself as the English officers who had come to arrest him entered his room (March 1, 1889).

PIGRES, pi'gréz (Lat., from Gk. Πίγρης). A Greek poet of the fifth century B.C.; supposed to have been the brother or son of Queen Artemisia of Caria. According to Suidas and Plutarch he wrote a poem entitled *Μαργύρης*, and he is now generally regarded as the author of the mock-heroic poem *Βαρραχομωμᾶχια* (*The Battle of the Frogs and Mice*), which was once attributed to Homer. Pigres is said to have been the first poet to introduce the iambic trimeter.

PIG-TAILED BABOON. A small, black baboon-like monkey, of Celebes Island (*Cynopithecus niger*), which has a rudimentary tail.

PIG-TAILED MONKEY. Either of two species of East Indian macaques, remarkable for their short curling tails. The best known is the short-haired one (*Macacus nemestrinus*), described by Buffon as the 'maimon,' which inhabits the Malay Peninsula and southward through Sumatra and Borneo. It is as large as a mastiff, and has great strength; and it was long ago related of it that the Sumatrans trained it to climb trees and throw down coconuts, but it is now believed that if this were ever true it must have been so only of females or young, as the old males become very fierce and unruly.

The Burmese pig-tailed monkey (*Macacus leoninus*) is distinguished by its longer hair, smaller size, and darker color. It has a limited distribution, is rare, and little known. See Plate of MONKEYS OF THE OLD WORLD.

PIGWEEED. A name given to various species of *Amarantus* (q.v.) and often also to certain species of *Chenopodium* (q.v.).

PIKA. The popular name of the curious little duplicidentate rodents of the genus *Lagomys*, related to hares and rabbits, but representing a distinct degenerate family, the *Lagomyidae*. They are sometimes called 'calling hares,' 'little chief hares,' and 'comies.' They are about the size and shape of a guinea-pig, and are not superficially at all like the hares, except about the nose, though the rounded ears are large and the tail very short. Three species at least are known, one in Europe and Asia, a second in Asia, and the third in the mountainous parts of the Western United States. The latter (*Ochotona princeps*) is seven inches long, the tail less than an inch. It is dark grizzled blackish above and dirty whitish beneath. It inhabits the higher parts of the mountains, generally just above the timber line. The pikas are somewhat gregarious, and numbers usually inhabit masses of rocky debris at the base of cliffs, where their squealing

note makes their presence known. They are timid, unsuspecting, and perfectly harmless animals. They feed entirely upon vegetable matter, and store up hay and dried vegetables—which they cut and lay in the sun to cure—as bedding and fodder for the winter. The Indians hunt and trap them for their skins, which they sew together into undergarments. See Plate of HARES AND PIKA.

PIKE (so called from its sharp snout and slender shape). The name of any one of several species of soft-rayed fishes of the family *Lucidae* (or *Esocidae*). They have an elongated body, slightly compressed posteriorly, and covered with scales. The head is long with a prolonged and depressed snout. The mouth is large, the lower jaw somewhat the longer, and well supplied with strong, sharp teeth. The dorsal and anal fins are inserted far back. There is a single genus, *Lucius* (*Esox*), with six species all restricted to the northern part of North America except one species (*Lucius lucius*), which is also found in Northern Europe and Asia. This, the 'common' or English pike, grows to a length of about four feet. The "general color is bluish, or greenish gray, with many whitish or yellowish spots . . . arranged somewhat in rows; the dorsal, anal, and caudal fins with roundish or oblong black spots." It is called both 'pike' and 'pickerel' in the United States. The greatest of the American pikes is the maskinonge (q.v.), of the Great Lakes, which differs little from the European species. The remaining species are described under PICKEREL.

All the pikes are known for their voracity and are hated by fish culturists because of their inroads upon other more desirable species. A pike willingly attacks any fish of its own size and preys freely on the smaller ones, even of its own species. Frogs are frequent prey; water-rats and ducklings are sometimes devoured. They spawn in spring in grassy shallows of the rivers and weedy waters in which they live, laying many thousands of eggs, which remain entangled in the vegetation until they hatch. The young pikes grow with great rapidity, and in England are known as 'jacks,' or 'pickerels.' The Scotch name is gedd, a term similar to those in the Scandinavian languages.

The pike is caught by means of nets, by the rod, by set lines, and by trimmers or jiggers, which may be briefly described as floats with lines attached to them, the line being so fastened that the bait swims at a proper depth, and that some yards of line run out when the bait is taken. In angling for pike various baits are used, such as a minnow, a portion of a fish, etc., and sometimes an artificial fly is employed with success. These are English methods. In the United States a commoner method is by trolling with a spoon-bait. They are also much caught through the ice of the northern lakes. See Colored Plate of AMERICAN GAME FISHES, accompanying article TROUT; and Plate of NEEDLE-FISH, PIKES, etc.

Various other fishes are often called pikes, as the gars, and pike-perches (q.v.). The 'Sacramento pike' (q.v.) is a chub; the 'picuda' is a barracuda.

PIKE (AS. *pic*, OF. *pique*, *picque*, Fr. *pique*, pike). A weapon of warfare used extensively till the introduction of the bayonet. Among ancient armies the Macedonians were famous for

their spear or pike men, who carried weapons fully 24 feet long, while among comparatively modern armies pikes averaged a length of from 12 to 14 feet. They were of stout wood, and were tipped with a flat-shaped iron spear-head, which sometimes had cutting edges. As a defense against cavalry, the pike, from its length and rigidity, was of great value; but though it survived the introduction of gunpowder, that event was really fatal to it. In pike formations a depth of several men was essential, but the growing use of artillery rendered this impossible. For the transition from pike to bayonet, see BAYONET. See also INFANTRY.

PIKE, WALL-EYED. See PIKE-PERCH.

PIKE, ALBERT (1809-91). An American author, born in Boston. He studied at Harvard, and in 1831 journeyed to Santa Fé by way of Saint Louis. In 1832 he explored the head waters of the Brazos and Red rivers, and went 500 miles on foot, to Fort Smith, Arkansas, in which State he settled. After editing the Arkansas *Advocate*, he was admitted to the bar, and in 1836 he edited the Arkansas Revised Statutes. He served as captain of cavalry in the Mexican War, at the beginning of the Civil War was Indian commissioner of the Confederate Government, and later served as brigadier-general, commanding bodies of Indians whose enlistment he had secured. In 1866 he settled as a lawyer at Memphis, where in 1867 he edited the *Appeal*. In 1868 he resumed his practice at Washington, D. C. Besides preparing a number of volumes for the Freemasons, he published *Prose Sketches and Poems* (1834), and *Nugæ* (1854), printed privately, and containing the "Hymns to the Gods," which had appeared in *Blackwood's Magazine* in 1839. His poetry, especially his "Hymns to the Gods," proves him to have been a man of considerable talent. He died in Washington, D. C.

PIKE, ROBERT (1616-1706). An American colonist, born in England. He emigrated to this country with his father, John Pike, in 1625, and settled in Newbury, Mass. Four years later he removed to the farm at Salisbury which was his home for the remainder of his life. He early became a man of prominence in the colony, was major of the local militia, and from the time he was twenty-eight years old until his death—with the exception of three years when he was at odds with the General Court—he held political office, being for a long time a member of the General Court itself, and later of the Board of Assistants. He was chiefly remarkable, however, as the representative of the first advocates in America of the people's right to free speech, to petition and to criticise their legislative bodies, and to demand acquittal in a court of law when not confronted with conclusive evidence. Though strictly orthodox in his own beliefs, he defended the right of the Quakers to the free expression of their views and criticised the General Court for its action against sectarians. For this he was disfranchised by that body. Though he believed in the possibility of witchcraft, he protested against the admission of 'spectre testimony' at the trials of supposed witches. Several were condemned in the towns about Salisbury despite his labors in their behalf, but, probably because of his influence, none were executed; and so this little group of villages was saved from sharing in the notoriety of Salem.

PIKE, ZEBULON MONTGOMERY (1779-1813). An American soldier and explorer, born in Lambertton, N. J. He was taken by his father, an army officer, to Bucks County, Pa., and then to Easton. At the age of fifteen he was a cadet in his father's regiment, became ensign March 3, 1799, and was made first lieutenant November 1, 1800. On August 9, 1805, he started from Saint Louis on an exploring expedition into part of the territory acquired by the Louisiana Purchase. After suffering many hardships and reaching the Upper Red Cedar (Cass) Lake, he returned to Saint Louis in April, 1806. He started on another expedition on July 1st, ascended the Missouri River and the Osage, into the present State of Kansas, and thence proceeded south to the Arkansas River. He ascended this to the present site of Pueblo, Col., viewed 'Pike's Peak' (named in his honor), and then went to the site of the present Leadville. While searching for the Red River, he reached the Rio Grande on Spanish territory, and was sent under guard by the Spanish Governor of New Mexico to General Salcedo at Chihuahua. After some delay he was escorted to the boundary, and on July 1, 1807, reached Natchitoches. He had been made captain in 1806 and was promoted to be major in 1808, lieutenant-colonel in 1809, and colonel in 1812. On March 12, 1813, he was nominated brigadier-general (though he was not confirmed by the Senate before his death), and was assigned to the principal army as adjutant and inspector-general. In the expedition against York (Toronto), Canada, he landed on April 27th, and stormed one of the redoubts. The retreating garrison blew up the magazine, and a descending fragment of rock crushed his spine and caused his death within a few hours. Pike published the results of his expedition in *An Account of an Expedition to the Sources of the Mississippi, and Through the Western Parts of Louisiana, and a Tour Through the Interior Parts of New Spain* . . . (1810). This contains much valuable information, but is poorly arranged and full of repetition. It was rearranged and reprinted in England in 1811. From this was made a French translation in 1812 and a Dutch translation in 1812-13. Consult *The Expedition of Zebulon M. Pike to the Headwaters of the Mississippi, Through Louisiana Territory, and in New Spain* (3 vols., New York, 1895). This contains the rearranged text, full notes, and an elaborate memoir by Elliott Coues.

PIKE-PERCH. The name given in America to a genus of perches, *Stizostedion*, and in Europe to species of a very nearly related genus, *Lucioperca*, because of their rather elongate body and the resemblance of the snout to that of a pike. They are true perches and inhabit the lakes and streams of Europe, Western Asia, and Eastern North America. There are several species in each genus, and all are important food fishes. They are usually under two feet in length, but *Lucioperca sandra* of Europe may reach a length of four feet, and *Stizostedion vitreum* of America a length of three feet and a weight of twenty pounds. The latter is a fish of many names in the United States, 'wall-eyed pike' being perhaps the most widespread and familiar—a name, like 'white-eye' and 'glass-eye,' due to the large prominent eye; 'dory,' 'yellow' or 'blue' pike, and 'jack salmon' are other local

names. It is brassy olive in color, with the lower jaw, belly, and lower fins pinkish. It is scattered in favorable waters all over the North-western States and the Mississippi Valley, and is caught both in nets and by angling.

A second species (*Stizostedion Canadense*) is more northerly in its distribution, and is known as 'sauger' and 'sand' or 'gray' pike. It is particularly a fish of the Great Lake region, and has a more cylindrical form and more spotted fins than the wall-eyed pike, from which it may also be distinguished by absence of the jet-black spot over the hinder spines of the dorsal fin. See Plate of PERCHES.

PIKE'S PEAK. A peak of the Rocky Mountains, in El Paso County, Col., near Colorado Springs (Map: Colorado, E 2). It was discovered by General Pike, U. S. Army, in 1806. Its height is 14,108 feet above the level of the sea, and it commands a magnificent and widely extended view of the great plains, and of a rugged, mountainous country containing many lakes and rivers. Pine forests cover the slopes to a height of 11,700 feet, above which the mountain consists of bare granite rocks. The summit was occupied by a meteorological station of the United States Signal Service from 1873 to 1888, and reoccupied by the Weather Bureau in 1892. A rack and pinion railroad to the top was opened in 1891.

PILASTER (ML. *pilasterum*, little pillar, diminutive of Lat. *pila*, pillar). An ornamental member in architecture, corresponding to the column and pier, but forming a part of the wall from which it projects. When it is not prominent and is lacking in capital and base, it is called pilaster strip. In Greek architecture it was called *anta*; in Roman buildings, as in Greek, the pilaster usually responded to a column, but in some cases, as in the beautiful arch at Tripolis, it was independent and richly ornamented. The pilaster was used in every style, but until the Renaissance was not as favorite a form as the engaged column. The decorative pilasters of the early Italian Renaissance were the most charming works of their class, and, though copied in design from Roman art, were more profusely used than in any other style.

PILATE (Lat. *Pontius Pilatus*). The Roman Governor of the territory comprising Judæa, Samaria, and a large part of Idumæa, which, after the deposition of Herod Archelaus in A.D. 6, became an Imperial province. His official title was procurator, and he resided in the prætorium at Cæsarea, going up to Jerusalem at the season of national feasts. He possessed complete judicial authority except in cases of Roman citizens, who had the right of appeal to Rome, but many of these functions were discharged by local courts, particularly by the Sanhedrin in Jerusalem; death sentences were confirmed and executed by the procurator. Pilate's term of service in Palestine was long, from the appearance of John the Baptist, through the ministry of Jesus, and while the early Church was gaining its first converts (A.D. 26-36). The early years of his administration were marked by strained relations between himself and the Jews, whose intense religious convictions and national pride he failed to understand. He was thoroughly hated, and, in one instance at least, the people appealed successfully to the

Emperor against him. Pilate is known chiefly from his connection with the trial and death of Jesus of Nazareth. After the Sanhedrin had condemned Jesus to death, they came to Pilate evidently expecting that he would ratify their decision without investigation. This, however, he refused to do. The Jews therefore presented charges of corrupt teaching, interference with tribute, and false claims of kingship against Jesus (Luke xxiii. 2), which brought him within the sphere of civil law. Pilate examined him privately and Jesus answered his questions frankly. As a result of the examination, Pilate was convinced that Jesus was politically harmless and wished to save him, but he feared to do so by peremptory release. In the end popular clamor prevailed, and personal and political considerations of a selfish nature outweighed Pilate's loyalty to the functions of a just judge. Pilate's rule in Judæa ended by his being cited to appear in Rome to explain certain acts of cruelty. Thereafter he disappears from authentic history. There are many traditions concerning the end of his life. One of these is connected with Mount Pilatus, near Lucerne, Switzerland, in a lake on which his body is said to lie. Consult, besides the lives of Christ, and Schürer's *History of the Jewish People in the Time of Jesus Christ* (Eng. trans., Edinburgh, 1886-90), especially, G. A. Müller, *Pontius Pilatus der fünfte Prokurator von Judäa* (Stuttgart, 1888).

PILATE, ACTS OF. See APOCRYPHA, section on *New Testament*.

PILATE, ARCH OF. An arch spanning the Via Dolorosa at Jerusalem, said to mark the spot where Jesus with the crown of thorns was presented to the Jews by Pilate with the words "Ecce Homo." The structure is probably a Roman triumphal arch.

PILATUS, pi-lä'tus, MOUNT. A peak of the Bernese Alps in Switzerland, rising from the western shore of the Lake of Lucerne (q.v.) to a height of 6998 feet (Map: Switzerland, C 2). It is visited by numerous tourists on account of the fine view to be had from the summit, which is reached by a rack and pinion railroad. The name is probably a corruption of *pilatus*, 'capped;' but according to a legend it is derived from Pontius Pilate, whose body is supposed to have been thrown into a little lake at the foot of the mountain, and whose ghost, as the legend goes, still haunts the place.

PIL'CHARD (formerly also *pilcher*, from Ir. *pilseir*, pilchard). A European fish (*Clupea pilchardus*), closely allied to the herring and the same thing as the sardine, sardines being simply young pilchards. (See SARDINE.) The pilchard occurs in vast schools along the western coast of Europe and in the Mediterranean Sea, and is taken by means of seines in enormous quantities for the European markets and preserving factories. It reaches nearly the size of the herring, but is rather thicker, and the outlines of the back and belly are straighter; the upper part of the body is bluish green, the sides and abdomen silvery white, the cheeks and gill-covers yellowish, and the dorsal fin and tail dusky. In Great Britain it is caught only along the Channel coast. See Plate of HERRING AND SHAD.

PILCOMAYO, pi'kó-mä'yó. A river of South America, the longest tributary of the Paraguay

River (q.v.). It rises in the Cordillera Real in Western Bolivia, and flows with no large deviations southeastward until it joins the Paraguay just below Ascunción (Map: Paraguay, E 8). In the lower half of its course it forms the boundary between Argentina and Paraguay. After descending from the Bolivian plateau and breaking through several ridges, it flows for the remainder of its course through the great plain of the Gran Chaco, partly through dense forests, partly through wide, marshy tracts, where the banks are submerged, and where the river divides into several parallel channels. It is here a sluggish stream with an average width of thirty yards, and so shallow and obstructed as to be almost completely unnavigable. The Pilcomayo has not yet been thoroughly explored, and its length is undetermined, but is estimated at 1200 miles.

PILE (AS. *pil*, from Lat. *pilum*, javelin, pestle, from *pisere*, *pinsere*, to pound). In engineering and architecture, a long post generally of wood, but often of iron, driven into soft soils to support a load or to form an inclosure against the entrance of water. Piles are known by different names, according to their character or use, the more important being: *Bearing pile*, one used to sustain a vertical load and the one generally meant when the word pile is employed without qualification; *sheet piles*, thick boards or timbers driven in close contact, often tongued and grooved, to inclose a space, to prevent leakage, etc.; *serew pile*, an iron shaft to the bottom of which is attached a broad-bladed serew with one or two turns; *disk pile*, an iron shaft to the bottom of which is attached a circular disk to give additional bearing power. The most common form of pile is the bearing pile of, usually, a roughly trimmed, slender tree trunk, or, less usually, of a squared or other dressed timber shape. The woods used for piles are spruce and hemlock for soft soils, pines, elm, and beech for firmer soils, and oak for compact soil. Engineers usually require that piles shall not be less than

falling weight. These leaders are usually braced back to the pile-driver platform by diagonal timbers. The sides of the hammer are grooved to slide between the leaders, and it weighs from 500 to 4000 pounds, usually about 2000 pounds. It is hauled to the top of the frame by a rope or chain attached to its top and passing over a pulley at the top of the frame, and thence to a hand windlass or the drum of a hoisting engine. In one kind of pile-driver the rope is attached to the hammer by a sort of tongs which is automatically opened by a tripping device when the top of the frame is reached, thus allowing the hammer to fall. In another form the rope is permanently attached to the hammer, which is set free by loosening a friction clutch, thus allowing the drum to unwind the rope which is pulled down with the hammer. The latter form of driver is the one least commonly used, and is the most expensive in first cost, but is generally regarded as the most efficient.

Drop-hammer pile-drivers are mounted on scows or cars, or may be skidded about on the platform timbers. A steam-hammer pile-driver consists of a steam cylinder in which a piston works, carrying a heavy weight or hammer on the end of the piston rod. This steam cylinder is vertical with the piston rod, extending downward, and is held between the tops of two or four uprights which serve to guide the hammer. The bottoms of these uprights are held together by a cast block pierced with a conical hole which fits over the partly sharpened head of the pile. The hammer has a cylindrical projection which passes through the hole in the base block to strike the pile. The piston stroke is usually about three feet, and the weight of the striking parts is commonly about one and one-half tons. This whole apparatus is swung between the leaders of a pile-driver frame by a rope exactly as is the hammer of a drop-hammer pile-driver. In operation the apparatus is lowered on to the pile until the pile carries its entire weight. By means of flexible hose connections with a steam boiler steam is admitted under the piston, raising it with its attached piston-rod hammer until at the top of the stroke a trip cuts off the steam and the hammer falls by its own weight, striking the pile a heavy blow. At the end of the down stroke the valves are automatically reversed and the stroke repeated. In this way the machine can deliver from sixty to eighty blows per minute, as compared with from six to fourteen blows for a trip drop-hammer driver, and from twenty to thirty blows for a friction drum drop-hammer. While the steam-hammer driver strikes blows having much less energy than those of a drop-hammer driver, it strikes its lighter blows so much more rapidly that it compares favorably with the best friction drum drop-hammer drivers in efficiency.

CONCRETE-STEEL PILE.

METAL SHOES FOR WOODEN PILES.

ten inches in diameter at the smaller end. Generally the pile is shaped for driving, and sometimes a pointed iron shoe is attached to the pointed end; the top is frequently bound with an iron band to prevent brooming.

Piles are sunk into the soil by several methods, the most common of which is driving by a hammer. The machines used to drive piles by a falling weight or hammer are known as pile-drivers. There are two general forms of such machines known as drop-hammer pile-drivers. In a drop-hammer pile-driver a heavy hammer of iron is pulled to the top of a lofty frame by hand or power and allowed to fall freely on to the head of the pile. The frame consists of two uprights called leaders about two feet apart and from ten feet to sixty feet long, which guide the

The two other forms of pile-drivers are the

gunpowder driver and the water-jet driver. The gunpowder driver is seldom used and is worthy of mention chiefly for its novelty. It consists essentially of a heavy hollow cylinder with its bottom resting on the pile and its top open, which is called the gun. Into the top of the gun fits a sort of piston carrying on its top a mass of iron weighing about 1500 pounds, which is called the ram. In operation the ram is raised, a cartridge of from two to three ounces of gunpowder is placed in the gun, and the ram is let fall. In falling the piston enters the gun, compressing the air and causing sufficient heat to explode the cartridge, when the expansive force of the powder forces the pile down and the ram up. A cartridge is thrown into the gun each time the ram ascends. With this machine thirty to forty blows per minute can be struck with a fall of from eight feet to ten feet. The water jet is not strictly a pile-driver, but it is such a well-known method of pile-driving that it merits mention here. The method is very simple; a jet of water is forced into the soil just below the point of the pile, thus loosening the soil and allowing the pile to sink either by its own weight or with very light blows. The water is conveyed to the point of the pile by a hose which is held to the pile by staples during sinking and pulled up to be used again after the pile is sunk.

SCREW PILE.

Timber piles sunk by the methods just described support their loads partly by the friction of the soil on the sides of the pile and partly as a column by the point resting on an impenetrable material. There are two methods of determining the supporting power of a pile: (1) to note its resistance to penetration under the last blow of the pile-driver hammer, and (2) to load the pile and observe the weight that it will safely stand. The former method is the one generally used, the latter being used simply as confirmatory evidence in doubtful cases. See FOUNDATIONS.

As previously stated, the two most common forms of iron piles are screw piles and disk piles. Sometimes the stem of such piles is of wood, while the screw and disk are of metal. Screw piles for engineering work usually have a shaft from three inches to eight inches in diameter, with screws from three feet to six feet in diameter. They are driven by rotating the shaft just as an ordinary wood screw is driven, capstan bars being usually employed to secure the screwing motion, although hydraulic screwing devices have been occasionally employed. Screw piles will penetrate all ordinary soils. They are seldom used in the United States, but are commonly employed abroad. Disk piles are sunk by the water-jet. At the ocean pier at Coney Island, New York, disk piles were used having wrought-iron shafts $8\frac{1}{2}$ inches in diameter and disks two feet in diameter and nine inches thick. Some of these piles stand seventeen feet in the sand, and carry loads of over six tons per square foot of disk. Consult Baker, *Treatise on Masonry Con-*

struction (New York, 1900). See FOUNDATIONS; LIGHTHOUSE; BRIDGE.

PILE (AS. *pil*, from Lat. *pilum*, javelin, pestle). In heraldry (q.v.), one of the charges known as ordinaries.

PILE-DRIVER. See PILE.

PILE DWELLING. See LAKE DWELLING.

PILES (from Lat. *pila*, ball), or HEMORRHOIDS. Small vascular tumors situated either within or on the verge of the anus. They consist of dilated veins containing either fluid blood or a solid clot, covered with inflamed, infiltrated or permanently thickened mucous membrane. They are termed *internal* when situated above or within the sphincter; *external* when below or outside it. Piles vary greatly in size and structure, and in the symptoms they produce. They may be merely little knots of varicose veins in the submucous tissue; these may in time increase in size, be forced in and out during defecation, become inflamed and strangulated, and even ulcerated and gangrenous. External hemorrhoids usually do not bleed; the internal variety, which extend above the sphincter for an inch or more, are soft, purple irregular masses, and bleed readily when irritated by hardened fecal masses. *Arterial piles* contain, besides a large vein, arteries of some size. These bleed easily and freely, but are comparatively rare. Children are occasionally afflicted with *capillary piles*, small, sessile tumors, which also bleed.

Hemorrhoids are caused by any circumstance which produces long-continued venous congestion in the rectum. Constipation, enlargement of the prostate gland, pregnancy, tumors of the uterus or its appendages, congestion or cirrhosis of the liver, certain diseases of the heart and lungs, sedentary occupations, and relaxing climate, are a few of the causes. Over use of harsh cathartics and horseback riding are also mentioned as factors.

The following are the general symptoms of this affection. The patient, after having experienced for a varying time a feeling of heat, fullness, and dull pain about the lower part of the bowel, becomes conscious of a foreign body in the anus; and, on examination, discovers a small tumor, which either remains outside or is retracted, according as it originated without or within the sphincter. This tumor gradually increases, and others form around it, until a mass at length results as large as a pigeon's egg, or larger. In its ordinary indolent state the tumor has little sensibility, and occasions comparatively little annoyance; but when inflamed it is exquisitely tender to the touch, and is the seat of burning and stinging sensations, rendering the evacuation of the bowels (and sometimes of the bladder also) difficult and painful. In women an inflamed pile may cause pain in the back, and other anomalous symptoms. In severe cases the patient can neither stand nor sit with comfort, and only finds relief in the horizontal position.

Piles may be prevented by active exercise, mild saline catharsis, a light laxative, non-stimulating diet. These measures may also avail to cure or hold in abeyance the affection in its earlier stages; and, with the exception of the first, are always indicated in conjunction with other means of treatment. Scrupulous cleanliness must al-

ways be observed. When inflamed, in addition to the above precautions, piles should be treated by absolute rest, warm fomentations, and the injection of cold water into the rectum several times a day. As the acute symptoms subside, astringent and sedative lotions, such as lead water and laudanum, and extract of hamamelis, may be applied. Internal piles that protrude must be pushed back; if they become strangulated, hot applications are to be used until reduction is possible. For the bleeding, which is sometimes severe, cold applications and injections usually suffice. Hemorrhoids occasionally become so troublesome as to make life a burden, and operation is the only measure that will bring relief. The tumors, if external, may be simply tied with ligatures at the base and cut off. Internal piles may be drawn down with forceps and treated in the same manner. In persistent cases the whole pile-bearing area of mucous membrane may be dissected off and removed, and healthy membrane brought down to take its place.

PILEUS, pi'lé-üs (Lat., cap). The cap-like top of a toadstool. See **BASIDIOMYCETES**.

PILEWORT. An herb. See **RANUNCULUS**.

PILGRIM (OF. *pellegrin*, *pelerin*, *peregrin*, Fr. *pélerin*, pilgrim, from Lat. *peregrinus*, foreigner, pilgrim, from *pereger*, being in foreign lands, from *per*, through + *ager*, field). One who visits some distant place for a religious purpose. The notion that particular localities possess special sanctity is widespread. The gods of primitive religions are local and can only be approached within their proper boundaries or at their peculiar sanctuaries. Hence, when their worshipers become scattered, a journey is necessary to offer devotion or ask for favors. A place where a theophany is supposed to have occurred is naturally considered as consecrated by the divine presence and particularly favorable for answer to prayer. Localities of importance in the history of a religion or in the lives of persons specially revered attract the interest and devotion of the faithful. In religions where self-mortification is considered meritorious or obligatory, the trouble and pains involved in a journey, particularly in times and places where travel is neither easy nor secure, have made of pilgrimage a meritorious act and pious duty. On the other hand, the journey affords opportunity to see the world, satisfies the love of adventure, and provides an outing, and this element is not to be overlooked in tracing the history of pilgrimage.

Pilgrimages are characteristic of many religions, as those of ancient Egypt, Persia in the Mithraic period, Syria, Mexico, and Peru, India, China, and Japan. The Greek and Roman custom of consulting the gods at local oracles, like Dodona and Delphi, is well known. In the early period of Hebrew history there were many local sanctuaries, and pilgrimages to some of them are clearly indicated, as Shiloh (I. Sam. i. 4), Ophrah (Judges viii. 27), Dan and Bethel (I. Kings xii. 30-33). The great Mohammedan pilgrimage to Mecca (see **HAJJ**; **MOHAMMEDANISM**) is a survival of pagan times. Besides this, which is obligatory on every Mussulman, there are numerous devotional pilgrimages, particularly to the tombs of saints. Kairwan (q.v.) in Tunis,

Wazan in Morocco, Kerbela in Mesopotamia (q.v.), and Masjid Ali in Irak are sacred cities, the last two in the estimation of the Shiites hardly second to Mecca.

The early Christians regarded certain places with special religious interest; above all, the Holy Land, and particularly the scenes of the passion of the Lord at Jerusalem. Other sacred places, too, were held to be fit objects of the same visits of religious veneration. The tombs of the Apostles Peter and Paul, and of the martyrs in the catacombs at Rome, are so described by Saint Jerome (*Commentary on Ezekiel*). The pilgrimage, however, preëminently so called, was that to the Holy Land; and even after Jerusalem had been occupied by the Mohammedans, the liberty of pilgrimage, on payment of a tax, was formally secured by treaty; and it was from the necessity of protecting pilgrims from outrage that the well-known military orders (see **ORDER**) had their origin. The Crusades (q.v.) may be regarded as a pilgrimage on a great scale, the direct object being to secure for the Latin Christians immunity of pilgrimage. On the other hand, the final abandonment of the Crusades led to a great extension of what may be called domestic pilgrimage, and drew into religious notice and veneration many shrines in Europe, which, after the lapse of time, became celebrated places of pious resort. The chief places of pilgrimage in the West were: in Italy—Rome, Loretto (q.v.), Genazzano, Assisi; in Spain—Compostela, Guadalupe, Montserrat; in France—Fourvières, Puy, Saint-Denis; in Germany—Oetting, Zell, Cologne, Treves; in Switzerland—Einsiedeln; in England—Walsingham, Canterbury, and many others of minor note. The pilgrim commonly bound himself only by a temporary vow of chastity and other ascetic observances, terminating with the actual visit to the place of pilgrimage, or at least with the return home. He wore a broad hat, a black or gray cloak, girt with a cincture, and carried a long staff. Those who had completed the pilgrimage to the Holy Land brought away a palm leaf and hence were called palmers. A string of scallop shells was the badge of a pilgrim from Compostela, a bottle or bell from Canterbury. Pilgrims had many privileges. They were considered holy men whose person was sacred, and were entitled to entertainment and assistance on their way. Hospices for their accommodation were established in many places, notably in Rome, and are a prominent feature of Jerusalem at the present day. In the course of time many unworthy persons joined the number and brought pilgrimages into disrepute. They have always been maintained in Italy, Spain, Southern Germany, and Switzerland; in France they fell into disfavor during and after the Revolution. In late years, however, pilgrimages on a very large scale, even from the United States, have visited the sanctuaries of Lourdes (q.v.), La Salette, and Paray-le-Monial (q.v.). Another popular European place of pilgrimage is Czenstochowa, in Russian Poland. A famous shrine of the New World is Saint Anne de Beaupré, near Quebec; and large numbers annually visit the place consecrated by the death of the Jesuit martyrs Father Jogues (q.v.) and his companions at Auriesville, N. Y. The Holy Land is visited still by many pilgrims from the Eastern churches, particularly Russian peasants, and a smaller number from Western Europe. For the history of Chris-

tian pilgrimages, consult Marx, *Das Wallfahren in der katholischen Kirche* (Treves, 1842); and for some of the most famous shrines, Northcote, *Celebrated Sanctuaries of the Madonna* (London, 1868).

PILGRIMAGE OF GRACE, THE. The name given to an uprising in the north of England in 1536. The destruction of the smaller monasteries by Henry VIII. angered the country gentlemen and the Commons, who had taken great pride in these institutions and had received educational and other benefits from them. They feared, too, that after this work was done, Cromwell, the King's evil genius, would plunder even the parish churches. This was the chief grievance which drove 60,000 men of Lincolnshire to rebellion. Though they soon dispersed, a more formidable uprising in Yorkshire took place under the lead of Robert Aske, a gentleman and barrister. Priests encouraged the movement. The rebels, calling their march the Pilgrimage of Grace, and carrying a banner embroidered with the five wounds of Christ, demanded a renewal of the connection with Rome, restoration of the monasteries, and punishment of Cromwell. As the King's forces could not cope with the insurrection, he promised to call a Parliament in the north to settle the grievances. The rebels thereupon returned to their homes; but, far from keeping his word, Henry not only put to death twenty leaders of the rebellion, but covered the whole north with gibbets.

PILGRIM FATHERS. A name given to those emigrants who came to America early in the seventeenth century on account of religious differences in England, and founded the colony of Plymouth. They were Separatists and members of John Robinson's congregation in Leyden, whither they had come from England. They are to be distinguished religiously from the Puritans of England. See CONGREGATIONALISM; MASSACHUSETTS; ROBINSON, JOHN.

PILGRIM'S PROGRESS, THE. A famous allegory by John Bunyan, the first part printed in 1678, the second in 1684. The first part describes the journey of Christian to the Celestial City; the latter, the journey thither of his wife, Christiana, and her children. This drama of the soul's progress through life was written in Bedford prison, probably in 1675-76, and not during Bunyan's earlier and longer imprisonment. The pilgrim idea of life was an old one, but was never worked out in so powerful a manner as by this humble Puritan, whose only helps were his Bible and Fox's *Book of Martyrs*.

PILGRIM'S TALE, THE. A poem erroneously attributed to Chaucer, as one of the *Canterbury Tales*. A confused story was told of it by the son of Thynne, who edited Chaucer's works in 1532, and is said to have printed it. But it is not found in either of Thynne's editions. It appeared in *The Courte of Venus*, a collection of verse published about 1536, in which it is credited to Chaucer. Only two fragments of this work exist in Oxford, one of which contains the *Tale*.

PILKINGTON, LETITIA (1712-50). An Irish adventuress, born in Dublin. She was the daughter of Dr. Van Lewen, and married Matthew Pilkington, an Irish clergyman, in 1729. Swift, then Dean of Saint Patrick's, in Dublin,

was attracted by her vivacity and ingenuous manners, and helped her improvident husband to get a position in London. Afterwards, the pair were divorced, and Mrs. Pilkington lived in Ireland and England, befriended by Colley Cibber, Samuel Richardson, and others. The *Memoirs of Mrs. Letitia Pilkington . . . written by herself, wherein are occasionally interspersed all her poems . . .* (3d ed., 1754), have been harshly criticised for their lack of truth, but they are written in an engaging style and include many anecdotes of Swift and bits of personal biography, not touched upon by others. Thackeray uses them freely in his *English Humorists*.

PILL (from Lat. *pilula*, abbreviated in mediæval prescriptions to *pil.*, plural *pill.*, pill, little ball, diminutive of *pila*, ball). The most convenient and popular form of medicine. Pills are globular masses of a size convenient for swallowing, and of a consistence sufficient to preserve their shape and yet not so hard as to be difficult of solution in the stomach or intestines. They are especially suitable for remedies which operate in small doses, as the metallic salts; substances whose action it is desired to retard until they have reached the intestines; bodies whose specific gravity is too inconsiderable to allow their suspension in aqueous vehicles; and substances which are disagreeable to the taste or smell. The pill form is, on the other hand, unsuitable for medicines which it is necessary to give in large doses; fluid or semi-fluid substances, such as oils, balsams, etc., which require a very large proportion of some dry powder to make them into a mass; and substances so insoluble that when exhibited in solid form they pass through the intestinal canal unaltered, as extract of logwood. Many substances, such as vegetable extracts, may be at once formed into pills without any addition; but most of them require an excipient for converting them into a pill mass. The excipients in common use are bread crumbs, soap, extract of licorice, mucilage, syrup, molasses, honey, castor oil, and confection of roses; the latter is probably the most generally useful, from its property of remaining soft for a considerable length of time. It is common to place pills in some fine powder to prevent them from adhering to each other and to conceal their taste. For this purpose licorice powder, wheat flour, starch, magnesia, and lycopodium are employed. Pills made in large numbers and by machinery are often coated with sugar, variously colored and flavored, gelatin, keratin, and other materials. Pills retain their moisture and activity much longer in bottles than in pasteboard boxes. The ordinary weight of a pill is five grains; if it much exceeds that weight it is too bulky to swallow conveniently, especially if it consists of vegetable matter. A pill much larger than this is called a bolus, while very small pills are known as granules. See CAPSULES.

PILLAR (OF. *pilier*, *pilier*, Fr. *pilier*, from ML. *pilare*, *pilarius*, *pilarium*, *pillare*, pillar, from Lat. *pila*, pillar, pier, mole). A term used by unscientific writers on architecture to designate a support of masonry, of any form—round, square, or polygonal—more properly called column or pier, according to its shape.

PILLAR SAINT, or STYLITE. One of a remarkable class of ascetics, chiefly of Syria, who,

with a view to separating themselves more completely from earth and fellow-men, took up their abode on the tops of pillars, and remained thus without descending to earth, exposed to all the variations of climate or sheltered only by a hut built on top of the pillar. The earliest of these and the most celebrated, was Saint Simeon or Simon Stylites, a Syrian monk, who was born near the close of the fourth century, and is said at first to have lived for ten years in extreme seclusion in his monastery in the neighborhood of Antioch, without ever moving from his narrow cell. Increasing in enthusiasm, about 423 he withdrew from the monastery, and built a pillar, on the top of which, only a yard in diameter, he took up his position. From this pillar he removed to several others in succession, each higher than its predecessor, till at last he attained to 40 cubits, or about 60 feet in height. In this life he spent 37 years. Many remarkable stories are told of his austerities, and he acquired the reputation of a miracle-worker. The fame of his sanctity brought crowds of pilgrims from the most distant countries to see him; and he is said to have converted many to the Church. A disciple of Simeon, named Daniel, succeeded to his reputation for sanctity, and to his mode of life, which he maintained for 33 years, in the still more trying climate of the shores of the Bosphorus, about four miles from Constantinople. In Syria there were many pillar saints as late as the twelfth century; after the sixteenth century they disappeared altogether. In the West there is only a solitary example. A monk named Wulfaicus, near Trèves, attempted the pillar life in the sixth century, but the neighboring bishops compelled him to desist, and destroyed his pillar.

PILLARS OF HERCULES. See HERCULES, PILLARS OF.

PILLAU, pil'lou. A seaport town, fortress, and bathing resort of Eastern Prussia, situated on the southern end of a tongue of land separating the Frisches Haff from the Baltic Sea, at the entrance to the former and about 25 miles west of Königsberg, with which it is connected by a navigable channel (Map: Prussia, J 1). It is the outer port of Königsberg.

PILL BEETLE. A beetle of the family Byrrhida, a term used by English collectors. The group is a small family of 200 to 300 species, of which about 40 occur in the United States. They are small insects, move very slowly, and when disturbed at once contract the limbs so completely that they look like inanimate objects.

PIL/LING, JAMES CONSTANTINE (1846—). An American ethnologist, born in Washington, D. C. He was educated at Gonzaga College in that city, and while with Major J. W. Powell on the Rocky Mountains Geological Survey (1872-79) had opportunity for studying aboriginal dialects. In 1881 he was appointed chief clerk of the Bureau of Ethnology, and ten years afterwards was made head of the same bureau in the Smithsonian Institution, Washington. He catalogued the *Linguistic MSS. in the Bureau of Ethnology* (1881) and made bibliographies of the following Indian languages, which were published by the Government: *Siouan* (1887), *Iroquoian* (1888), *Muskhogeian* (1889), *Algonquin* (1891), *Atha-*

pascan (1892), *Chinookan* (1893), *Salishan* (1893), and *Wakashan* (1894).

PILLNITZ, pil'nīts. A palace and ordinary summer residence of the royal family of Saxony, in a beautiful situation, six miles southeast of Dresden. Pillnitz acquired a historic interest from the meeting of Leopold II. and Frederick William II. held in the castle in August, 1791, when the declaration of Pillnitz was framed, in which Austria and Prussia affirmed that the affairs of King Louis XVI. (then a prisoner in the Tuileries, after his ineffectual attempt to escape from France) were a matter of common interest to the sovereigns of Europe, and expressed the hope that common cause would be made for his restoration. The Emperor and the King of Prussia were resolved to use force in order to effect this result; but any immediate interference on their part was rendered unnecessary by Louis's acceptance of the Constitution as modified by the National Assembly, after which he was again placed on the throne.

PILLORY (OF, Fr. *pilori*, from Prov. *espilori*, pillory, from Lat. *speculatorius*, relating to an observer, from *speculator*, observer, investigator, scout, spy, from *speculare*, to view, from *specula*, watch-tower, from *specere*, to see). An obsolete instrument for the public punishment of criminals. It consisted of two parallel boards, joined by sliding hinges and fixed like a sign-board on the top of a strong pole, supported on a wooden platform elevated above the ground. A large circular hole with its centre in the line of junction of the two planks received the neck, and two corresponding holes of smaller size, one on each side of it, the wrists. The pillory existed in England before the Conquest, in the form of the *halsfang* or catch-neck, an instrument by which the neck only was confined; according to the 'statute of the pilory' of Henry III. it was originally intended for "forestallers, users of deceitful weights, perjury, forgery, etc.," and all such dishonorable offenses. Its use was confined to this class of offenders till 1637, when restrictions were put upon the press, and all who printed books without a license were put in the pillory. From this time it became the favorite mode of punishing libelers, authors and publishers of seditious pamphlets, or of strictures on the Government, and many eminent men suffered on the pillory. The inadequacy of the pillory as a means of inflicting punishment, however, became apparent, for to those who were popular favorites it was no punishment, while those who were objects of popular dislike were ill-used to such an extent as occasionally to suffer death. In France the pillory was anciently called *pilori*, and later *carcan*, from the iron collar by which the criminal's neck was attached to the post; but punishment by this mode was abolished in that country in 1832. It was also in use in Germany, where it was known as the Pranger. The use of the pillory was abolished in England in 1837, and in the United States, where early statutes had provided for its use in the case of some offenses, in 1839.

PIL/LOW, FORT. See FORT PILLOW.

PILLOW, GIDEON JOHNSON (1806-78). An American lawyer and soldier, prominent as an officer in the Mexican War, and on the Confederate side in the Civil War. He was born in

Williamson County, Tenn.; graduated at the University of Nashville in 1827; and commenced the practice of law in Columbia, Tenn., in the following year. He was commissioned brigadier-general and placed in command of the Tennessee volunteers on the outbreak of the Mexican War in 1846. He served for a short time in the Northern campaign under General Taylor, then joined General Scott before Vera Cruz; commanded the right wing of the American army at Cerro Gordo, where he was severely wounded; was promoted to be major-general in April, 1847; and participated in the battles of Contreras, Churubusco, and Chapultepec. After the war he was charged with insubordination by General Scott, but was honorably acquitted by a court of inquiry. He then returned to the practice of the law in Tennessee, and took an active interest in politics. On the outbreak of the Civil War he entered the Confederate service and was appointed brigadier-general. He was in command against Grant at the battle of Belmont on November 7, 1861; was second in command at Fort Donelson under General Floyd, with whom he escaped on the night before the surrender to Grant by General Buckner (see FORT HENRY AND FORT DONELSON); was temporarily relieved from command; and subsequently served under Beauregard in the Southwest and acted as chief of conscripts in the Western Department.

PILLSBURY, HARRY N. (1872—). An American chess-player, born in Boston, Mass. A strong taste for mathematics early led him to the study of chess. At the International Chess Congress held at Hastings, Eng., in 1895, he won the world's championship over a group of famous experts, the first American since Paul Morphy to attain to that honor. He became the principal American representative at foreign tournaments and in international cable matches, and was always distinguished for his strong, careful, and original play. His more recent successes were at Vienna in 1898, where he tied with Tarrasch for first place, at London in 1899, where he divided second honors with Janowsky and Maroczy, and at the American tournament in Buffalo in 1901, where he won first prize.

PILLSBURY, JOHN SARGENT (1828-1901). An American merchant and politician, born at Sutton, N. H. He received a common-school education, and in 1855 settled at the Falls of Saint Anthony, Minn., where he opened a hardware store. In 1872 he became a partner in the firm of Charles A. Pillsbury & Co., flour-millers. From 1864 to 1876 he was a State Senator, and from 1876 to 1882 was Governor. During his administration he persuaded the people to pay off the State debt, which they had repudiated twenty years before. He gave generously to the University of Minnesota and other public institutions, built a town hall for Sutton, his birthplace, and founded a library for workmen in East Minneapolis.

PILLSBURY, PARKER (1809-98). An American abolitionist, born at Hamilton, Essex County, Mass. He removed to Henniker, N. H., in 1814; about 1829 began to drive an express wagon between Boston and Lynn; afterwards was a farmer; in 1835-38 studied at the Gilmanton (N. H.) Theological Seminary, and in 1838-39 at the Andover Theological Seminary.

In 1839 he was licensed to preach, and in 1839-40 was pastor of the Congregational Church at New London, Merrimack County, N. H. He then withdrew from the ministry, enlisted in the anti-slavery movement, was for a short time editor of the *Herald of Freedom*, at Concord, N. H., and then became a lecturer in New England and the West. In 1854 he visited England in the interest of the movement. He was fanatical in his views and violent in his methods. He joined Phillips in the meetings of the American Anti-Slavery Society and elsewhere in opposition to the reelection of Lincoln. His attacks upon the Church, owing to the attitude of the pulpit toward anti-slavery reformers, were particularly bitter. Upon the dissolution of the American Anti-Slavery Society, whose continuance for philanthropic work among freedmen he had urged, he became a preacher for free churches at Salem and Toledo, Ohio; Battle Creek, Mich.; and other towns of the West. He published some pamphlets, including the text of a lecture, "The Plague and Peril of Monopoly" (1887); *Acts of the Anti-Slavery Apostles* (1884); and *The Church as It Is* (1885). The *Acts* contains an autobiographical sketch.

PIL/MOOR, JOSEPH (1739-1825). One of the founders of Methodism in America. He was born at Tadmouth, in the North Riding of Yorkshire; educated at the Kingswood school; entered the ministry in 1765; came to America in 1769 and labored in New York and Philadelphia. He returned to England in 1774; because he was not included by Wesley in the 'legal hundred' he was offended and retired in 1785. Returning to America, he became a member of the Protestant Episcopal Church, and was ordained by Bishop Seabury the same year. He still ministered in New York and Philadelphia, the last twenty years of his life being spent as rector of Saint Paul's Church in the latter city, where he died. His journal in manuscript is the property of the Methodist Historical Society of Philadelphia; a portion of this has been published under the title *The Western Pioneers* by John P. Lockwood (London, 1881).

PILOCARPINE. See JABORANDI.

PILON, πῆλον', GERMAIN (c.1535-90). A French sculptor of the High Renaissance. He was born in the Faubourg Saint Jacques, Paris, about 1535, as is known by a document of 1573. His father was a stone-cutter from whose instruction he passed to that of Pierre Bontemps. At the age of twenty-three he was engaged with Pierre Bontemps in the execution of a fine monument of Francis I. in the Church of Saint Denis. In 1561 was undertaken the extremely important group in the Louvre of three Graces supporting a bronze vase, which formerly contained the heart of Henry II. After the year 1565 Pilon was much occupied with the decoration of the monument of Henry II. in Saint Denis. All the sculpture of this monument was formerly attributed to him, but it is now known that only the kneeling statue of the Queen and the reclining statue of the King are his. Other equally fine work on this monument is by Freymyn Roussel, Laurent Regnaudin, Dominique Florentin, and Girolamo della Robbia. One of the most charming of the works attributed to Pilon is the mantel now in the Louvre which formerly stood

in the Chateau of Villeroy. In 1571 he had lodgings in the Hotel de Nesle and assisted in arranging the triumphal entry of Charles IX. into Paris. In 1573 he was appointed comptroller-general of the coinage. It is supposed that he made the great bronze medals of the Valois, the most interesting of which are those of Catharine de' Medici and Henry III. In 1587 he made the monument of the Abbé Joseph Foulon for a chapel of Sainte Geneviève in Paris. Pilon died February 5, 1590. His reputation as a sculptor of the High Renaissance in France is second only to that of Goujon. Consult: Lami, *Dictionnaire des sculpteurs français* (Paris, 1898); Paulstre, *La Renaissance en France* (ib., 1885).

PILOT (OF. *pilote*, Fr. *pilot*, probably from OF. *piloter*, *pilotier*, to sound with plummet and line; probably connected with Dutch *peillood*, sounding-lead, from *peilen*, MDutch *peylen*, *pijlen*, from MDutch *peyelen*, to gauge, from *pegel*, capacity of a ship's gauge + *lood*, MDutch *loot*, Goth. *lōþ*, Ger. *Lot*, AS. *lead*, Eng. *lead*). A person who makes a business of conducting vessels in and out of port, through narrow channels, up rivers, or along coasts where the navigation is specially difficult or dangerous. He is possessed, or supposed to be possessed, of sufficient knowledge of all reefs, rocks, shoals, currents, and other dangers to navigation in the region for which he professes to be, or is licensed as, a competent pilot. Except in little frequented ports, pilots are usually members of a pilot association or company organized under authority of law; and they are required to pass examination as to fitness before being appointed or licensed. The pilotage fees are not retained by the pilot in each case, but are paid into a common fund which is divided among the members according to the rules of the association. In order to furnish a sufficient fund for the payment of an adequate supply of pilots, pilotage is compulsory in many ports, but in these places vessels usually need pay only half pilotage if they do not actually take a pilot. In ports which are not very easy of entrance marine insurance policies usually require that local pilots be employed under penalty of forfeiture of the policy. Masters of vessels frequenting particular ports very commonly take out pilot license to reduce the expense of entry and departure. Pilots may be found off all large ports. They are usually carried in small fast sailing schooners, but in recent years some pilot boats are steam vessels. Pilot boats carry numbers which are placed on the sail or conspicuously painted on the hull (if a steamer). A century ago a pilot was a necessity for a ship entering a locality unfamiliar to the captain or master, but the great improvement in charts, the increase in the number of light-houses, buoys, beacons, and other aids to navigation, and the change of motive power from sail to steam in more than half the large vessels of the world have contributed to lessen the pilot's importance.

PILOT FEE. The sum of money paid to a pilot for his services in guiding a vessel in or out of a harbor is called *pilotage*. Where a pilot is engaged by the proper officer of a vessel the pilotage is a lien on the vessel. Consult Benedict, *American Admiralty* (New York, 1870).

PILOT, THE. A sea-tale by James Fenimore Cooper (1823). It is the story of an attempt

made during the American Revolution to kidnap some prominent Englishmen for exchange. An American frigate off the English coast takes on a pilot, who is the famous Paul Jones. The plot fails, and the crew are rescued from peril, arising from Colonel Howard, an American loyalist refugee.

PILOT CHART. The Pilot Charts of the North Atlantic and of the North Pacific Oceans, issued monthly from the United States Hydrographic Office, Navy Department, Washington, give, in a form suitable for use by seamen, a general view of the climatological conditions prevailing over each of these oceans during the successive months of the year, with certain deductions therefrom, along with a large amount of additional information, meteorological and otherwise, which is likely to prove of value to navigation. The charts are drawn on the Mercator projection, that of the North Atlantic extending from the equator to 60° north, and from the meridian of 10° east to 102° west; that of the North Pacific from the equator to 70° north and from 75° west to 117° east. Each of the charts is published some days prior to the first day of the month to which it refers. They are lithographed in three colors, black, blue, and red, the color serving, within certain limits, as an index to the character of the information conveyed. The base of the chart, along with such information as is invariable throughout the year, is printed in black. Among other matter this embraces the lines of equal magnetic variation (see SHIP'S COMPASS; MAGNETISM; TERRESTRIAL) for the current year, than which no feature of the chart is more highly appreciated by navigators, owing to the almost universal employment of the Pilot Chart as a track chart, upon which the position of the vessel from day to day is plotted. See SAILING.

For the purpose of climatological study the surface of the ocean is supposed to be divided into rectangular areas by the even five-degree parallels of latitude and meridians of longitude, 5°, 10°, 15°, etc. The Pilot Chart for any month gives in blue for each of these areas the atmospheric pressure and temperature prevailing under normal conditions, the average force of the wind, the number of hours within the month during which the wind may be expected to blow from a given quarter, and the frequency of calms, derived from a discussion of the observations taken within the same month during previous years. All of this is shown symbolically upon the face of the chart. In addition to this there is also given in blue a brief text, containing a forecast or statement of the average conditions that may be expected during the month for the more frequented parts of the ocean, the probability of storms, the nature of these storms, the frequency of fog (upon the Pilot Chart of the North Atlantic Ocean this is also shown graphically upon the face of the chart), and the limits within which dangerous masses of floating ice may be expected. The proper sailing and steamship routes for the given month and the limits of the trade winds are also exhibited.

The information given in red is in the nature of a review. Upon the Pilot Chart of the North Atlantic Ocean it comprises a brief account of the main features of the weather over that ocean during the month preceding the date of publica-

tion of the chart. The path followed by the centre of each of the more important barometric depressions that have occurred within that period is shown, and the force of the winds which accompanied them, the latter on the Beaufort scale. The region through which fog has been frequent is also shown. Upon the Pilot Chart of the North Pacific Ocean there appears the average track followed by the centres of the barometric depressions for the month that occurred during the ten-year period 1878-1887; also the tracks followed by the centres of the various classes of typhoons, those terrific storms which render navigation in East Asiatic waters so fraught with danger. Upon both charts is given in red the last reported position of floating derelicts, wreckage, buoys, and other obstacles to navigation. Recently reported icebergs and field ice are also shown, all of these being plotted upon the chart precisely where last sighted, in order that the mariner may have the dangers which menace his vessel constantly in view, without dependence upon his memory and without reference to any publication save the chart before him.

Other features of the chart are the list of equator crossings for several future months, intended for the use of vessels bound on distant voyages; the list of new charts recently published and of additions and corrections to old; the storm warnings displayed by the United States and by other maritime nations, all of which are shown graphically. In addition to these the land space of the chart is always devoted to a discussion of some topic of interest to navigators, such as studies in the law of storms, the experience of various vessels in recent cyclones, recent improvements in the theory and practice of navigation, the relative advantages of different sailing routes, and other similar subjects. The reverse of the chart is also frequently utilized for this purpose, one of the interesting publications of the United States Hydrographic Office being the chart which appears annually upon the back of the Pilot Chart, showing the drift of sealed bottles which are cast overboard in various parts of the ocean and find their way to distant shores.

As in the days of Maury, so now the United States Government is still the pioneer in this class of publications for the benefit of seamen. The first edition of the Pilot Chart of the North Atlantic Ocean appeared in December, 1883, that of the North Pacific Ocean in January, 1894. The German Government and also the English have recently entered the field, each of these having in January, 1901, begun the publication of a chart of the North Atlantic embodying many of the features of the American Pilot Chart. The German chart bears the title *Nordatlantische Wetterauschau*, and is published monthly by the Deutsche Seewarte, Hamburg, Germany. The British Pilot Chart extends also over the Mediterranean Sea, and is published monthly by the Meteorological Office in London. See HYDROGRAPHIC OFFICE.

PILOT-FISH, or ROMERO. A fish (*Naucrates ductor*) of the family Crangidae, resembling the mackerel, except that there are no finlets succeeding the dorsal fin. It gets to be about two feet long; the general color is silvery grayish-blue, five dark transverse bands passing around the whole body. Its flesh is said to be very delicate, resembling mackerel in flavor, but it is not often

met with in the markets. It is the only species of the genus, and is widely distributed through the tropical seas. It is often seen in the company of a shark, and is therefore very commonly supposed to direct the shark to its prey. The facts probably are that the pilot-fish, in company with sharks and other fishes, follow in the wake of vessels for the purpose of picking up anything edible that may fall from the ship. It is not impossible that the pilot-fish finds it a decided protection against enemies to be associated with the shark, and in this way has developed the habit. A related fish, one of the amberfishes, is often called 'shark's pilot;' it is *Scriola zonata*, of the American coast from Cape Cod to Cape Hatteras; and a West Indian demoiselle (family Pomacentridæ, *Eupomacentrus leucostictus*) is called 'black pilot,' or 'cockeye pilot.' The name 'pilot-fish' is also given to the 'round' whitefish (*Corcogonus quadrilateralis*) of the Great Lakes.

Consult: Goode, *Fishery Industries* (Washington, 1884); Bennett, *Gatherings of a Naturalist in Australia* (London, 1860). See Plate of HORSE MACKERELS AND ALLIES.

PILOT KNOB. A conical hill in Iron County, Missouri, 75 miles southwest of Saint Louis (Map: Missouri, F 4). It is about a mile in diameter at its base, and consists of beds of iron ore, porphyry, and porphyry conglomerates. The ore is hard, specular, steel-gray in color, extremely brittle, and with a faint lustre. A few miles to the northwest is Iron Mountain (q.v.).

PILOT MOUNTAIN. A mountain in North Carolina. See ARARAT.

PILOT SNAKE. (1) A North American blacksnake which is black or brown above, with or without darker squarish spots; the belly is very darkly clouded, and the head not banded. It is common from New Jersey to Texas, especially in the Middle States, where it is often called 'mountain blacksnake,' but is known to the mountaineers of the Alleghenian ranges as 'pilot snake.' It is a denizen of forests to a great extent, hiding in hollow logs and in holes of old trees. It climbs trees easily, and in the spring feeds largely upon birds and their eggs, and fledglings; otherwise its prey is mainly mice, rabbits, and other small animals. It is not only entirely harmless,

PILOT SNAKE (*Coluber obsoletus*).
1, Top of head; 2, profile.

but remarkable for gentleness, making little resistance to being handled, and soon becoming tame. Stejneger says this species deposits its eggs in hollow stumps and similar places, where they hatch in early summer. Consult Cope, *Crocodylians, Lizards, and Snakes* (Washington, 1900).

(2) A local name in the Eastern States for the copperhead (q.v.).

PILOTY, pã-lô'tê, KARL VON (1826-86). A German historical painter, famous for having revived the color element in the modern

German school of painting. He was born in Munich, October 1, 1826, the son of the lithographer Ferdinand Piloty (1786-1844), and was first instructed by his father. Entering the Academy at the age of twelve, he was even then an excellent draughtsman, assisting his father, whose lithographic business he managed after the father's death. Impressed by the coloring of the works of Gallait and Biéve, exhibited at Munich in 1843, he made a study trip in 1847 to Venice, where Paul Veronese especially claimed his attention. He also studied in Antwerp and Paris (1852), becoming thoroughly imbued with the spirit of the Belgian and French colorists, as is shown by his "Young Mother Dying" (1849), and "The Nurse" (1853). The latter, which was particularly commended for its brilliant technique and the realistic conception, foreboded a new era in the school of Munich, then under the influence of Cornelius's (q.v.) cartoon-painting. The success of this picture brought him the commission to paint for the Maximilianeum "The Founding of the Catholic League in 1609" (1854). The great triumph achieved with his "Seni Before the Body of Wallenstein" (1855, New Pinakothek, Munich) led to his appointment as professor at the Academy in 1856. His remarkable career as a teacher soon made the school of Munich the foremost in Germany. On a visit to Italy in 1858 he made the studies for his "Nero on the Ruins of Rome" (1861, National Museum, Budapest). His principal works during the next decade include "Galilei in Prison" (1861, Cologne Museum), "Godfrey of Bouillon and the Crusaders Approaching the Holy Sepulchre" (1862, Maximilianeum, Munich), and the "Death of Caesar" (1865, Hanover Museum), which is considered his most perfect work as regards composition. He was called to Berlin in 1869, but was induced by the personal appeal of King Louis II. to remain in Munich, and given the commission to paint "The Triumph of Germanicus" (1873, New Pinakothek), a replica of which is in the Metropolitan Museum, New York.

On the death of Kaulbach in 1874, Piloty was appointed director of the Academy, and soon after his appointment he began the huge allegorical painting of "Monachia" (completed 1879) for the new City Hall. Strangely conspicuous as his only biblical subject appears the parable of "The Wise and Foolish Virgins" (1881, Metropolitan Museum, New York). His last works were "Under the Arena" (1883), "The Council of Three in Venice" (1885), and "The Death of Alexander the Great" (1886, National Gallery, Berlin), which he left unfinished, succumbing to a painful disease at Ambach, on the Starnberger See, July 21, 1886.

His brother FERDINAND (1828-95), born in Munich, studied under Schorn at the Academy and worked subsequently under Karl's influence. His name is favorably known through historical frescoes in the National Museum, Munich, the town hall at Landsberg, and the castles of King Louis II. Among his oil paintings may be mentioned "Queen Elizabeth Reviewing Her Army in Sight of the Armada" (Maximilianeum), and "Sir Thomas More in Prison Visited by His Daughter" (Wiesbaden Gallery). He also deserves notice as an illustrator for the Schiller and Shakespeare Galleries. Consult: Regnet, *Münchener Künstlerbilder*, ii. (Leipzig, 1871); Pecht,

Deutsche Künstler des 19. Jahrhunderts, iii. (Nördlingen, 1881); Muther, in *Allgemeine deutsche Biographie*, xxvi. (Leipzig, 1888); and Rosenberg, *Geschichte der modernen Kunst*, iii. (ib., 1889).

PILPAI, pil'pi. See BIDPAI.

PILS, ISIDORE (1813-75). A French historical and military painter, born in Paris. He was the pupil of Lethière, and of Picot; studied at the Ecole des Beaux-Arts and won the Prix de Rome in 1838. His picture "Rouget de Lisle Singing the Marseillaise" (1845) attracted much attention. After the Crimean War he painted several rather formal, heavily colored military pictures, such as "The Battle on the Alma" (1861, Versailles Museum), and "Disembarkation of the Troops in the Crimea." He also decorated (1875) the ceiling of the staircase in the new opera-house in Paris with allegorical subjects. He was appointed professor at the Ecole in 1863, and was made a member of the Institute in 1868, and an officer of the Legion of Honor in 1867. He received a first-class medal, Paris Exposition, in 1867, and a medal of honor at the Salon of 1861. His art resembles Picot's, but is more realistic. Consult Becq de Fouquières, *Isidore Pils* (Paris, 1876).

PILSEN, pil'zen (Bohem. *Plezeň*). The second largest city of the Austrian Crownland of Bohemia, situated in a fertile valley at the confluence of the Mies and the Radbusa, 68 miles southwest of Prague (Map: Austria, C 2). It is well laid out and has many fine structures, among which are the Gothic Saint Bartholomew's Church (1292), with the highest spire in Bohemia, 337 feet; a town hall in Renaissance style, built in 1556, containing the banquet hall in which Wallenstein (q.v.) received the oath of fidelity from his generals; a number of museums; various schools and gymnasia; and a municipal brewery. The brewery occupies a complete district of the town, the cellar alone being four miles long. Pilsner beer is famous all over the world. Aside from its breweries, Pilsen has wire works, bell foundries, paper mills, refineries, glass-blowing establishments, copper works, potteries, etc. The city is governed by a burgomaster and a council of 36 members.

Pilsen's population is increasing rapidly. In 1900 it was 27,232, mostly Czechs. In its early days Pilsen was fortified and during the Hussite Wars it suffered severely. In 1634 twenty-four followers of Wallenstein were hung in the market place. The first printing press in Bohemia was set up in Pilsen (1468).

PILZ, pilts, VINCEZ (1816-96). An Austrian sculptor, born at Warnsdorf, Bohemia. He studied at the Vienna Academy, at first painting, then sculpture under Kähssmann and Bauer, and in Rome (1849-55) was the pupil of Tenerani and Cornelius. After his return to Vienna he was influenced by Führich and afterwards by Rahl, under whose direction he produced numerous reliefs, statues, and groups. These include "Science and Commerce," for Windsor Castle; the two "Winged Horses" in front of Memorial Hall at Philadelphia, and in Vienna the "Neptune Group" at the Exchange, six statues of antique celebrities for the Museum, ten of composers for the Conservatory, and several of generals for the Arsenal, besides many others for various public buildings.

PIM, BEDFORD CAPPERTON TREVELYAN (1826-86). An English admiral, born at Bideford, Devonshire. He was educated at the Royal Naval School, and later took part in the search for Sir John Franklin. He was in the Crimean War, was dangerously wounded in China in 1857, and the next year was promoted to be commander. While on the Central American station, in 1859, he surveyed the Nicaragua Canal route and later organized a company to construct a railroad over this route, which failed to secure subscriptions. He was retired from the service in 1861, though his name was left on the list and he was in 1885 promoted to be rear-admiral. In 1873 he was called to the English bar and he was returned to Parliament in 1874-80. His writings include *The Gate of the Pacific* (1863), *An Essay on Feudal Tenures* (1871), and *The War Chronicle* (1873).

PIMA, pē'má. One of the leading tribes of the Piman stock (q.v.). Before being collected upon Gila River and Salt River reservations, Arizona, where they now reside, they roamed, jointly with the Papago, who are practically the same people, over all the territory from the middle Gila southward to Sonora, Mexico. According to their own traditions, which seem to be confirmed by archeological evidence, they formerly lived farther to the northeast, in the Salado River valley, where they had permanent pueblo towns and irrigating canals. Being driven out by hostile tribes, they gradually moved down the Gila valley, halting on their way long enough to build and occupy the noted Casa Grande ruins. In their new homes on the Gila they ceased to build substantial structures and contented themselves with dome-shaped huts of poles covered with thatch and earth. They retained their agricultural habit, fertilizing their fields by means of extensive irrigation canals, and cultivating corn, beans, pumpkins, melons, and cotton, men and women working together. They also prepare a sort of bread from the mesquite bean, and a liquor from the great Zaguara cactus. The women make pottery and weave beautiful water-tight baskets. (See Colored Plate of INDIAN BASKETS, under BASKET.) They were brought under the influence of Spanish missionaries at an early period, but revolted under their chief, Don Luis, in 1751, destroying all the missions, with every other Spanish settlement in their country. They were subdued after about two years of fighting and have since remained at peace with the whites, although until recently obliged constantly to defend themselves against the raiding Apache. They bear a high reputation for courage, industry, and honesty. They number on the two reservations 4950. For about seventy years the weaker Maricopa (q.v.) have been associated with them. See PIMAN STOCK.

PIMAN STOCK. An important group of cognate tribes occupying nearly the whole of the west coast and Sierra Madre region of Mexico and Arizona from the Gila River southward into Jalisco, and including, besides other tribes and subtribes, the Huichol, Mayo Opata, Papago, Pima, Tarumari, Tepehuan, and Yaqui. According to Buschmann, Gatschet, Brinton, and others they, together with the Nahuatlán tribes, are in fact an extension of the great Shoshonean stock (q.v.) of the United States. As a rule they are sedentary and agricultural, nearly in the culture

states of the Pueblo tribes, but perhaps not quite so far advanced in house-building. Owing to the nature of their country, which makes inter-communication generally difficult, their systems of government are usually communal rather than tribal. Although as a body not aggressive, some of their tribes, notably the Yaqui and Tepehuan, have maintained a determined resistance to the Spanish and the Mexicans. The whole number may be about 120,000, of whom the Tarumari make perhaps one-half.

PIMENTO. See ALLSPICE.

PIMPERNEL (OF., Fr. *pimpernelle*, from ML. *pimpernella*, *pimpinella*, *pipenella*, *pipinella*, with the original initial *b* assimilated to the following, *bipinella*, *bimpinella*, *bibanella*, *pimpernel*, from Lat. *bipennis*, two-winged, from *bi*, two + *penna*, *pinna*, wing), *Anagallis*. A genus of annual and perennial plants of the natural order Primulaceae, natives chiefly of temperate climates, with beautiful but small flowers. Several species are cultivated in flower gardens; others are weeds. Among the best known are the scarlet pimpernel (*Anagallis arvensis*); the blue pimpernel (*Anagallis carulea*), a form of the preceding; and the bog pimpernel (*Anagallis tenella*). These are all European species. The water pimpernel (*Samolus Valerandi*), also called brookweed, is a European plant of the same order and of almost worldwide distribution, growing in watery gravelly places. It has racemes of small white flowers.

PIN (AS. *pinn*, from ML. *pinna*, pin, nail, peak, Lat. *pinna*, *penna*, feather, wing, fin, pen). Probably the pin in its most primitive form of a spike, thorn, or fish-bone was employed long before the earliest needle and thread, as a means of fastening a garment together. (See NEEDLE.) Among the remains of the lake dwellers of Central Europe have been found a great number of pins, some of bone, others of bronze. Many of these are quite elaborate, with ornamental heads, while others are rudely fashioned. Some have double stems and a few have been found in form exactly like the modern safety pin. Examples of artistically wrought pins are found among Egyptian as well as Greek remains. Ancient Roman bronze pins and bone hair-pins, with ornamental heads, have been found at Pompeii. The Romans also made very elaborate fibulae, the prototype of the modern brooch. That simple pins, consisting of heads and shank with a sharpened point, were much used and highly esteemed by the nations of antiquity is proved by the frequent allusions to them in proverbs and other literature. As a requisite of the toilet, pins of iron wire were made in England during the fifteenth century; brass wire pins were introduced from France in 1540 by Catharine Howard, Queen of Henry VIII. The invention of the process of drawing wire was the foundation of modern pin manufacture, and for years the industry was confined to the two countries, France and Germany, where this process was invented. Brass wire pins were first made in England in 1826. The industry was most successful and spread rapidly, so that within ten years it was well established at Gloucestershire, Bristol, Birmingham, and London, and the pin-makers of the last-named city had formed a corporation.

At first pins were made by filing a proper

length of wire to a point and then twisting a piece of fine wire around the other extremity. The complete process involved thirteen or fourteen operations, requiring the labor of as many different persons. Most of these processes were performed by hand tools as distinguished from automatic machinery, and in many cases a pin at a time. Toward the close of the eighteenth century various inventors were at work devising machines for shortening this complicated process. In 1797 a solid-headed pin was made by Timothy Harris, of England. The blanks were placed in a two-part mold in which prints at the proper place represented the pin-head. Into this mold an alloy of lead and antimony was poured, which solidified and formed a solid head to the pin. Successive improvements followed, the most important of which was the machine invented by Lemuel Wellman Wright, of the United States, in 1824. This did little more than make solid heads to the pins, by a process in principle like that used for nail-making—viz., by driving a portion of the pin itself into a counter-sunk hole. The action, however, was automatic, and consisted in an arrangement by which the wire was seized in two small grooved cheeks. When both cheeks are placed face to face, the wire is held tightly in the groove with a small portion projecting, a small ram or hammer connected with the machine strikes on the projecting portion described, and compresses it into a small cup-shaped depression, and thus the head is formed. In 1831 a machine for making perfect solid-headed pins, like those now in use, was invented by John Ireland Howe, a physician in Bellevue Hospital, New York City. The following year a company was organized to make pins after his patents, which, six years later, moved to Derby, Conn.

The modern pin-making machine, without the aid of hands, completes the pin in all respects except the coloring and polishing. First, a reel of wire as it comes from the wire-drawer is placed in the rear of the machine, and the end of the wire is taken hold of by a pair of nippers, which pull it over a *straightening-board*, and pass it on completely straightened, until it is seized by two cheeks, when a cutter descends and cuts it off, leaving the projecting part for the head; on the withdrawal of the cutter, the hammer flies forward, and makes the head as before described; the cheeks open and the pins drop on to a sloping metal plate, finely grooved, down which they slip with the heads upward, until the end which is to be pointed comes in contact with a cylindrical roller with a grinding surface, which soon grinds points upon them, by the operation of two or three ingenious arrangements; the first is, that the grooved surface of the plate by which the pins descend terminates a little above the grinding roller, then a slight depression is given to the sloping plate, and also to the roller, so that one end is an inch or two lower than the other; therefore as the pin descends the groove, and is thus brought down the inclined plate, until it lies on the smooth part, where it is highest, and its end in contact with the grinding roller which is revolving, the pin itself is compelled by the friction of the roller to turn round, and gradually descends from the upper to the lower part of the inclined plate, and then falls into a box placed to receive it. These operations are performed so rapidly that they

can scarcely be perceived by the eye, and the pins, beautifully pointed, fall into the box in a stream. They are then yellowed, tinned, and prepared for papering.

Samuel Slocum, of Connecticut, invented the first pin-sticking machine. It was introduced into Dr. Howe's factory in 1841. The modern sticking machine is worked by two children; one feeds the machine with pins, the other with papers. The first part of the machine is a box, about 12 inches long by 6 inches broad, and 4 inches deep; the bottom is made of small square steel bars, sufficiently wide apart to let the shank of the pin fall through but not the head, and they are just as thick as the space between the papered pins. The lower part of the bottom of the box is made to detach itself as soon as the row of pins is complete, and row after row at regular intervals is received and passed down a corresponding set of grooves, until they reach the paper, which, as before described, is pinched into regular folds and pierced to receive the pins, which, by the nicest imaginable adjustments, come exactly to their places, and are pressed into them.

The same general process is followed in the making of safety pins, only here the process is more complex, as not only must the wire be cut and pointed, but it must be bent to the desired shape, and in certain styles of pins a sheath or catch for the point must be attached. The machines are entirely automatic in their action, and require but little attention.

Enamel-headed pins are largely made at Aix-la-Chapelle, Germany. Great quantities of needles are also made in the same city and the enamel-headed pins were made, at first, to utilize the imperfect needles. Now, however, they are made in such quantities that wire shanks are specially prepared for this purpose. Enamel, or glass, is spun into a rod about three-sixteenths of an inch thick. The end of this glass is kept viscous by a gas jet. Into this soft substance the workman plunges the pin-shank, and by a complex whirling motion detaches a bulbous mass from the rod which adheres as a head to the pin. It is said that a workman can head from 25,000 to 30,000 pins daily.

Black or mourning pins are made of iron wire, heated in a muffle till the proper tint is obtained; or they are coated with a suitable varnish, which is afterwards hardened by storing the pins.

STATISTICS. The chief pin-manufacturing centres are located as follows: In France, at Aix-la-Chapelle, Germany; at Birmingham, England; and, in the United States, principally in Connecticut. The growth of the industry in the United States is shown by the following figures taken from the Twelfth Census, Washington, 1902: In 1850 there were four pin factories in the country, having a combined capital of \$164,800, and a combined annual product of \$297,550. In 1900, 50,167,817 gross of pins were produced, valued at \$898,054. Of these 47,338,429 gross were common or toilet pins; 1,189,104 gross were hair-pins; 1,640,284 gross were safety pins.

PIÑA (pá'nyá) CLOTH (Sp., pineapple). A very beautiful fabric made of the fibres of the leaves of the pineapple plant (*Ananas sativus*), and other allied species. (See BROMELIA.) It is of a delicate, soft, transparent texture and a yellowish tint. This cloth, which is made in Manila, re-

sembles horse-hair cloth, because the threads both of warp and weft are each single unspun fibres, consequently only small pieces can be made; the workers have, however, a plan of joining the fibres of the coarser kinds end to end, so as to make warp threads of considerable length. Piña cloth is very strong, and the better sorts far excel the finest lawns in texture. It is chiefly employed in the manufacture of ladies' pocket-handkerchiefs, which often have their costliness much increased by beautiful embroidery.

PINACATE BUG. Any of the tenebrionid beetles of the genus *Eleodes*, especially common in the Western United States. They are large, smooth, clumsy, wingless, black beetles, which congregate in large numbers under stones and pieces of wood. They defend themselves when disturbed by elevating the hinder portion of the body and discharging an oily fluid.

PINAFORE, H. M. S. A popular comic opera by Sir Arthur Sullivan, produced in London May 28, 1878. The libretto, by W. S. Gilbert, is a droll satire on current topics, the germ of which is "Captain Reece" in the *Bab Ballads*.

PINAKOTHEK (Ger., from Gk. *πινακοθήκη*, *pinakothékē*, picture-gallery, from *πίναξ*, *pinax*, picture, *θήκη*, *thékē*, receptacle). Among the Hellenes, a term used to designate a room or building near a temple, for the preservation of pictures brought as votive offerings to the gods. The Romans applied it to the entrance to the atrium of a house, which often contained statues, pictures, and other objects of art. Pinocoteca is the usual Italian term for a gallery of paintings; but the most celebrated collection bearing this name is the Pinakothek in Munich, erected in 1826-36, after designs by Klenze, the architect of the Glyptothek. The New Pinakothek was completed in 1853, and in it are placed the works of contemporary artists. The main gallery is one of the most important in its contents in Europe, especially for works of the early German and Italian schools. It was the earliest important public gallery formed in Germany, but during the last half century has not kept pace with that of Berlin. The largest hall in the building is devoted to ninety-five works by Rubens, and there are a number of Raphaels. There are altogether over 1300 paintings, including specimens of Cimabue, Giotto, Leonardo da Vinci, Correggio, Titian, Michelangelo, Dürer, Rembrandt, and Van Dyke. It comprises the best works of the royal collections, these being arranged with regard to their various schools, in nine halls and twenty-three compartments. The building is itself a monument of art, one of its corridors being divided into twenty-five loggie frescoed by Cornelius, with works illustrative of the history of the fine arts in the Middle Ages. The lower story of the building contains 9000 drawings by the old masters; the original drawings for Cornelius's loggie; and a cabinet of more than 300,000 engravings. There is also an important collection of Etruscan and other vases, and other works of antiquity.

PINAR DEL RÍO, *pê-nâr' dël rê'ô*. A province of Cuba, occupying the western end of the island, and bounded on the north by the Gulf of Mexico, on the east by the Province of La Habana, and on the south by the Caribbean Sea (Map:

Cuba, B 4). Its area is 5000 square miles. The Cordillera de los Organos, reaching a height of 2500 feet, runs lengthwise through the province, and the land slopes gradually to the coasts on either side, which, especially in the southwest, are low and marshy. The southern slope is the celebrated Vuelta Abajo, where the finest tobacco in the world is grown. Tobacco is the main product. Sugar and coffee, and in the lowlands sea island cotton, are also grown, and there is extensive lumbering and some copper-mining. The population in 1887 was 225,891, and in 1899 173,064. The capital is Pinar del Río.

PINAR DEL RÍO. The capital of the province of the same name in Cuba. It is situated on the south slope of the mountains, 90 miles southwest of Havana, with which it is connected by rail (Map: Cuba, B 4). It is the centre of the tobacco industry of the Vuelta Abajo, and a good road connects it with the port of Coloma. Population, in 1899, 8880.

PINARIA GENS. An ancient patrician tribe at Rome, who, with the Potitii, were believed to have entertained Hercules and to have been taught the conduct of his worship, becoming his hereditary priests. According to the legend, Appius Claudius bought the secrets of the rites from the Potitii, who were thereupon destroyed by Hercules, while the Pinarii continued in existence until late times, though without great importance.

PINAS'TER. A kind of pine (q.v.).

PIN-BORER, or SHOT-BORER. Any of several of the bark-boring beetles (family Scolytidæ), which in issuing from their food-plants leave holes through the outer bark, usually of very small size. See BARK BEETLE; AMBROSIA BEETLE.

PINCH (from OF., Fr. *pincer*, to pinch, of unknown origin). A term used in connection with mineral deposits to indicate a marked narrowing of the vein or bed. Pinches may be caused by movements in the rocks, or by irregularities of deposition.

PINCH, TOM. Mr. Pecksniff's clerk in Dickens's *Martin Chuzzlewit*, a modest, good-hearted, guileless fellow, very fond of playing the organ. His sister Ruth, a pretty girl devoted to Tom, marries John Westlock.

PINCHBACK, PINCKNEY BENTON STEWART (1837—). An American lawyer and politician of African descent, born in Macon, Ga. He was educated at the public schools in Cincinnati, Ohio, commanded colored troops in the Federal army during the Civil War, and was a Louisiana State Senator in 1868-71. He was acting Governor of Louisiana in 1872 and was elected to Congress the same year. In 1873 he was commissioner to the Vienna exhibition from Louisiana, and he was made a member of the Board of Education of that State in 1877, and served as a trustee of the Southern University in 1883 and 1885. He studied law at the Straight University and was admitted to the bar in 1886.

PINCHBECK (named from its inventor, Christopher *Pinchbeck*, a London clockmaker of the eighteenth century). An alloy of copper and zinc, usually in the proportion of five parts of

the former to one part of the latter. It has a color resembling red gold, and was formerly largely used in making watch-cases and similar articles in imitation of gold.

PINCH'ES, THEOPHILUS GOLDRIDGE (1856—). An English Assyriologist. He was born in London, learned his father's trade of die-sinking, and at nineteen began to study Assyrian. In 1900, after twenty-two years of service, he retired from the British Museum, where he had been employed in the department of Egyptian and Assyrian antiquities. He was closely connected with the publication of the *Cuneiform Inscriptions of Western Asia* and the *Cuneiform Texts from Babylonian Tablets*, both issued by the British Museum; and wrote many articles in *Hastings's Dictionary of the Bible*. He published besides *The Old Testament in the Light of the Historical Records and Legends of Assyria and Babylonia* (1902).

PINCHWIFE. A character in Wycherley's comedy *The Country Wife*, a jealous husband who tries to keep his young and ignorant wife from society, lest she prove unfaithful. The unsophisticated wife, Margery Pinchwife, is the counterpart of Agnes in Molière's *L'Ecole des Femmes*, from which the comedy is borrowed. The Pinchwives appear as Moody and Peggy in Garrick's adaptation *The Country Girl*.

PINCIAN (pīn'shī-an) **HILL**, or **MONTE PINCIO**, mōn'tā pin'chō. A hill at Rome, 164 feet in height, forming a spur of the Quirinal, from which it is separated by a small valley. It was not included among the seven hills of Rome or regarded as a part of the city. It was famous as the site of magnificent gardens, including those of Aclilius Glabrio, of the Anicii, where the Villa Medici now stands, and of Lucullus, and therefore bore the name of *Collis Hortorum*. It is now the fashionable promenade of Rome and commands fine views of the city and surrounding country.

PINCKNEY, pink'nī, CHARLES (1758-1824). An American statesman, born at Charleston, S. C. He studied law and was chosen to the Provincial Legislature when just of age. He was a member of the Continental Congress in 1785 and in 1787 of the National Constitutional Convention. He was Governor of South Carolina from 1789 to 1792, and in 1790 presided over the convention which framed the State Constitution. From 1796 to 1798 he was again Governor, and from 1798 to 1801 was a member of the United States Senate. From 1802 to 1805 he was Minister to Spain, and secured a renunciation on the part of that country of her claims to the Louisiana territory. He was again Governor in 1806-08, was a member of the Legislature in 1810-12, and was a strong advocate of the War of 1812. From 1819 to 1821, in the National House of Representatives, he opposed the Missouri Compromise. He was a man of liberal ideas and favored the abolition of primogeniture in South Carolina, the removal of Jewish disabilities, and a system of free schools. He wrote a series of letters signed *Republican* (1800), which strongly advocated the election of Jefferson to the Presidency.

PINCKNEY, CHARLES COTESWORTH (1746-1825). An American soldier and statesman,

born at Charleston, S. C., son of Charles Pinckney, Governor of South Carolina. He was educated in England, at Oxford and the Middle Temple. After studying for a time at the Royal Military Academy at Caen, France, he returned to America in 1769, and began the practice of the law at Charleston. He served in the first Provincial Congress of South Carolina in 1775, was elected captain of a provincial regiment in the same year, and became colonel in October, 1776. He was afterwards one of Washington's aides-de-camp, participated in the battles of Brandywine and Germantown, and, returning to the South in 1778, joined the expedition to Florida. In 1783, he was promoted to be brigadier-general, but, the war being over, he returned to his practice at Charleston. He was a prominent member of the United States Constitutional Convention in 1787; of the State Convention which ratified the Federal Constitution, and of the convention which in 1790 framed a constitution for South Carolina. Sent to France in 1796, as United States Minister, he was received with studied discourtesy by the Directory, which finally forced him to leave the country; nor on his return as a joint commissioner with Elbridge Gerry and John Marshall was his reception more favorable. (See X. Y. Z. CORRESPONDENCE.) Talleyrand assured the commissioners that a gift of money was a necessary preliminary to the negotiations, and that a refusal might bring on war. Pinckney is said to have answered: "War be it, then; millions for defense, sir, but not one cent for tribute!" On his return to the United States a war with France seemed imminent, and he was appointed a major-general. He was the Federalist candidate for Vice-President in 1800 and for President in 1804 and 1808, and was the third president-general of the Society of the Cincinnati.

PINCKNEY, THOMAS (1750-1828). An American diplomat and soldier, born at Charleston, S. C. In 1753 he was sent to England with his brother, Charles Cotesworth Pinckney, to be educated; was admitted to the English bar in 1770; and returned to Charleston in 1772. Entering the Continental army as a lieutenant in 1775, he served as aide to Lincoln, D'Estaing, and Gates successively, taking a conspicuous part in the battles of Stone Ferry (June 20, 1779) and of Camden (August 16, 1780), at the latter of which he was wounded and taken prisoner, remaining in confinement until the close of the war. He was Governor of South Carolina in 1789-1791, was Minister to England in 1792-1794, and in November, 1794, was sent on a special mission to Spain, where he negotiated an important treaty (signed October 17, 1795), guaranteeing to the United States the free navigation of the Mississippi, with privileges of deposit at New Orleans for at least three years. Returning in 1796, he was the Federalist candidate for Vice-President in this year, and was a member of Congress in 1799-1801). In the War of 1812 he served as major-general in command of the Sixth Military District, and at the battle of Horse Shoe Bend completely defeated the Creek Indians. Subsequently he retired from public life and spent his last years in Charleston.

PINCKNEYA (Neo-Lat., named in honor of C. C. Pinckney), GEORGIA BARK, or FEVERTREE. A small tree, *Pinckneya pubens*, occasionally

found in low or swampy land in Florida, Georgia, and South Carolina. It belongs to the natural order Rubiaceæ, has large oval leaves, and beautiful terminal clusters of purple-spotted flowers. It is used by the country people as a substitute for quinine.

PINC-PINC, or **TINC-TINC**. A small South African bird (*Cisticola textrix*), so called from its ringing metallic cry, often repeated as it hovers in the air. It is chiefly but wrongly known as the alleged builder of a wonderful nest, the real fabricator of which is the cotton-bird (q.v.).

PINDAR (Gk. Πίνδαρος, *Pindaros*). The most famous of Greek lyric poets. He was born near Thebes in Bœotia, c.522 B.C., and probably died soon after 445, the date of his latest known poem. A conservative in politics and religion, a singer of the athletic prowess of the old Æolian and Dorian nobility, he seems to belong to a more ancient order than that of the great Athenians of the fifth century B.C. Apart from the magnificence of his style, the chief points of interest in Pindar for us are that: (1) He was before the recovery of Bacchylides from an Egyptian papyrus the only Greek lyric poet who could be studied in a considerable body of work; (2) he is the representative of a provincial, colonial, and in some ways larger Greece than that in which we are wont to see only a foil to Periclean Athens; (3) he is the first extant Greek writer to proclaim the immortality of the soul and to portray a future judgment; (4) he shows us the Greek myths in transition from their treatment by Hesiod, the older epic, and the lost lyrics of Stesichorus to the forms which they assumed upon the Attic stage.

Only the outline of his life is known. His earliest extant ode, the tenth Pythian, dates from about his twentieth year, before which time he is said to have studied under the best musical and poetic masters of Athens and Thebes, and to have been the pupil or the rival of the Bœotian poetesses, Myrtis and Corinna. An early poem overlaid with mythic ornament, is said to have called forth from the latter the famous admonition: "One should sow with the hand and not with the whole sack." Pindar's family belonged to the noble clan of the Ægeids which had widespread connections in Thera, Sparta, and Cyrene. His deep religious feeling caused him to cultivate intimate relations with the priesthood of the great shrines, especially that of Delphi, where his name was publicly honored for centuries. He seems to have traveled widely to all parts of the Greek world from which his national reputation brought him commissions. At the court of Hiero in Syracuse he may have witnessed the famous eruption of Mount Etna, so magnificently described by him in the first Pythian and by Æschylus in the *Prometheus Bound*. He composed hymns or encomia for the priests of Ammon, for Alexander of Macedon, Arcesilaus of Cyrene, Theron of Agrigentum, Hiero of Syracuse, and for the noblest families of Thessaly, Rhodes, Corinth, Ægina, Athens, and Tenedos. No other Greek poet has so wide a geographical range. None presents so vivid a picture of the dazzling diversity of greater Hellas; none so adequately expresses the underlying spiritual unity preserved by the common language and religion, and

the tradition of the great Panhellenic temples and games. His Hellenic patriotism has been questioned because he says so little of Marathon and Salamis and in praise of Athens. As a citizen of a 'Medizing' State, he could hardly have said more. Tradition has it that he said too much to please the Thebans, who fined him for the line cited from a lost dithyramb: "O splendid, violet-crowned, glorious Athens, famed in song, pillar of Hellas, city divine." The legend adds that the reward bestowed by the Athenians more than paid the fine.

Pindar and his contemporary Simonides represent the culmination of the Greek choral lyric composed with music to be sung by trained choruses of youths and maidens, as distinguished from the personal lyric of a Sappho or Alceus recited or half chanted to a slight accompaniment on the strings. Only fragments remain of Pindar's hymns to the gods, peans, dithyrambs, processional odes, dancing songs, dirges, and encomiums. But we possess practically entire the four books of his Epinician or triumphal hymns composed in honor of the victors at the four great national games—the Olympian, Pythian, Isthmian, and Nemean. The victor in the Olympic games received such honors as Rome and the modern world would bestow only upon the triumphant soldier. The victory was celebrated on the spot by festivities generally impromptu, and later at the victor's home by triumphal processions, banquets, and serenades often repeated for many anniversaries. If the victor was rich or had wealthy patrons, a Pindar, Simonides, or Bacchylides would be commissioned to write a special hymn to be sung during the procession or at the banquet by a trained chorus of his comrades. A large part of such a poem was conventionally predetermined. The victor, his clan, and his city must be celebrated. The great commonplaces of athletics, the praise of youthful pluck and endurance and of the beauty of young manhood, must be touched upon. There must be a word of admonition to moderation, and perseverance in well-doing; a prayer for the continued blessing of heaven, a deprecation of the 'jealousy' whether of gods or men, which Greek feeling attached to all preëminence. The poet's task was to ennoble this commonplace by stately and melodious utterance, to transfigure the whole in the light of the splendor and magnificence of the Olympian or Pythian festival, to raise the petty and personal into relation with the larger life of Hellas, to exhibit the transient success of the hour as the natural flowering of the glorious tradition of family, clan, and city. To this end Pindar employs the myth, which fills the central portion of the ode and often seems to have little connection with the immediate theme, but which closer study shows to be chosen with an art that we can sometimes only divine, either to express the dominant mood of the occasion or to connect the hero with the mythic past. The English reader may compare the treatment of the legend of the golden fleece in the fourth Pythian with the leisurely epic handling of the same theme in Morris's *Life and Death of Jason*.

It is customary to describe Pindar's sublimity by comparing him to the eagle or the lonely Alpine peak. His style is untranslatable and indescribable. Horace compares it to a torrent that has burst its banks. Boileau, Cowley, Gray, and

the long line of eighteenth-century authors of Pindaric odes, thought to reproduce it by jerky, irregular rhythms, abrupt transitions, and bombastic diction. Matthew Arnold praises it as "the grand style in simplicity." Myers's beautiful translation into archaizing English prose reproduces the matter excellently, but hardly the manner. It is "the grand style in simplicity" doubtless. But Pindar's simplicity is compatible with an "intoxication of style," a polysyllabic sonority, a cyclopean phrase architecture, a kaleidoscopic flash of metaphor, and above all an organ roll of word music which no modern tongue can compass. The best translation is that of Myers. Carey is the most readable of the older translators in verse. The chief editions are those of Böckh (the foundation), Schneidewin-Dissen, Christ (Teubner text, and larger edition with Latin notes), Fennell, Gildersleeve (Olympian and Pythian Odes). The best comment and criticism will be found in Croiset's *Pindare* (2d ed., Paris, 1886); in Fraccaroli, *Le Odi di Pindaro* (Verona, 1894); in Jebb, *Lectures on Greek Poetry* (London, 1893), and his paper in the third volume of the *Journal of Hellenic Studies*, and in Gildersleeve's *Introduction*.

PINDEMONTÉ, pèn-dā-môn'tā. IPPOLITO (1753-1828). An Italian poet, born at Verona. He was educated at Modena, and in 1778 he went to Rome, where he was admitted into the Arcadia. Here he conceived the idea of translating the *Odyssey*. With this idea in view, he went to Naples and Sicily, visiting many places connected with the legend of Ulysses. At Florence he made the acquaintance of Alfieri, and he saw him again at Paris, whence he passed to London, Berlin, and Vienna, returning to Verona in 1791.

Pindemonté's chief works are the *Poesie and Prose campestri* (1788-94), the form of which is cast in the Greek and Latin mold, and the inspiration of which is largely English; the epistle, *I scpoleri*, written in response to Foscolo's poem of similar import; and an excellent blank verse version of the *Odyssey* (1818-22). His lesser works comprise many treatises, discourses, and letters; a tale, *Clementina*; a novel, *Abaritte*; a number of tragedies, of which the best is the *Arminio* (1804), dealing with the story of the conqueror of Varus; and other versified compositions, such as the *Francia*, which celebrates the opening of the States General at Paris in 1789, and his *Sermoni*. Consult the edition of his *Poesie originali* (Florence, 1858); the *Arminio*, in the 3d ed. of Verona, 1812; the *Odissea* (Florence, 1891); Montanari, *Storia della vita e delle opere di Ippolito Pindemonte* (Venice, 1856).

An elder brother of Ippolito was GIOVANNI PINDEMONTÉ (1751-1812), also a poet of some merit. He rose high in political circles at Venice, and became Podestà of Vicenza, but falling into disfavor, he had to seek refuge in France in 1796. In 1802 he played a part in the legislative body at Milan. He wrote tragedies and lyrics, the latter of elevated inspiration, but imperfect in form. Consult his *Opere drammatiche* (1804-05), and his *Poesie e lettere*, edited by Biadego (Bologna, 1883).

PINDHÁREES, pín-dā'rēz, or **PINDÁRIS** (Marathi, *Pindhāri*, *Pendhāri*, plundered, from *pendha*, bundle of grass + *hāri*, one who takes).

The name of marauding companies of mercenaries, who remained in arms after the fall of the Mogul Empire. Eventually, between 1804 and 1817, they became in effect a formidable warlike State, dangerous to English rule, and the terror of the native populations. In the year 1816 alone they destroyed 339 villages in British territory. The next year Lord Hastings, with forces amounting to 120,000 men, completely routed the united Mahratta and Pindhāree armies, consisting of 200,000 men and 500 guns. From this blow the Pindhārees did not recover.

PIN'DUS. A mountain range of Northern Greece, between Epirus and Thessaly. See GREECE.

PINE (AS. *pin*, from Lat. *pinus*, Skt. *pīn*, pine; connected with Gk. *πίτυς*, *pitya*, Oir. *ith*, grain, Skt. *pītu*, sap, *pīta*, pine, *pā*, to drink, AS. *plūme*, *plyme*, from Lat. *prunum*, plum, *prunus*, plum-tree, from Gk. *πρῶνον*, *prounon*, *πρῶνον*, *prounon*, plum, *πρῶμνη*, *proumnē*, plum-tree; for the phonological changes of *r* to *l*, and of *n* to *m*, cf. Eng. *pilgrim*, from Lat. *peregrinus*, stranger), *Pinus*. A genus of trees of the natural order Coniferae. Nearly two-thirds of the species are natives of the northern part of the Western Hemisphere, the others occurring in the temperate and subarctic portions of Europe and in Africa, extending as do some of the American species into the tropics upon the high mountains. The genus is readily distinguished by narrow, linear needle-like leaves, growing usually in clusters of two, three, or five, surrounded at their bases by a sheath of membranous scales; and in bearing its seeds in cones which usually mature the second year, some species the third or later years. Pines embrace some of the most ornamental and useful trees, their size varying from shrubby specimens, which usually grow at high elevations or latitudes, to trees of great size.

GROUPING OF PINE-NEEDLES IN SHEATHS.
1, *Pinus monophylla*; 2, *Pinus Pinaster*; 3, *Pinus Sabiniana*; 4, *Pinus Lambertiana*.

Pines grow in almost every kind of soil and situation, from the bleak mountain side to the plain of almost pure sand. They are more or less gregarious in habit and frequently cover extensive areas to the almost total exclusion of other

PINES

WHITE PINE (*Pinus Strobus*).

species, as in the pine barrens of North America. The thickened epidermis and reduced surface of the needles, which are in fact not true leaves, check transpiration and fit the trees admirably for the situations in which they often grow.

One of the most scientific systems of classification, that given by Engelmann in the Transactions of the Saint Louis Academy of Science for 1882, is based upon rather technical characters. By others artificial groupings are made, based upon the number of leaves in the cluster and the position and character of the cones. The following scheme, adapted from Veitch, shows the relationships of some of the more common species:

Strobi, leaves in bundles of five; cones pendulous; scales thin, blunt; seeds winged—*excelsa*, *lambertiana*, *monticola*, *strobus*.

Cembra, leaves in fives; cones erect or horizontal; seeds large, obscurely winged—*albicaulis*, *Balfouriana*, *Cembra*, *flexilis*.

Edules, leaves in bundles of one-fifth; cones subterminal; scales thickened; seeds large, very obscurely winged—*monophylla*, *parryana*, *edulis*, *cembroides*.

Tæda, leaves in threes; cones subterminal or lateral; scales much thickened, with sharp prickles; seeds winged—*coulteri*, *palustris*, *ponderosa*, *Tæda*.

Pinaster, leaves in twos; cones lateral, often clustered, mostly persistent; scales thickened, blunt or spiny—*contorta*, *echinata*, *municata*, *Pinaster*.

Sylvestres, leaves in twos; cones subterminal, small mostly falling off; scales slightly thickened; seeds with elongated wings—*Banksiana*, *halepensis*, *resinosa*, *sylvestris*.

The white pine (*Pinus strobus*) is one of the most important timber trees of North America. Its range extends from Newfoundland to Minnesota and southward to the mountains of Georgia. It attains a height of 75 to 150 feet, with a diameter of 4 feet. The wood is white or light yellow, soft, straight-grained, and not very resinous, although some resin is obtained from it. It is easily worked and is largely used in building, cabinet work, etc., being especially in demand for doors, frames, window sash, blinds, shingles, etc. This tree is becoming scarce in the Northern United States and the adjacent parts of Canada. It is one of the most rapid-growing coniferous trees, and as an ornamental has no superior in the northeastern part of the United States. It is propagated from seed, and the young seedlings require some shade. It is not considered as hardy as the Scotch pine, but is longer lived.

The yellow, long-leaved, or Georgia pine (*Pinus palustris*), a tree of the widest distribution and greatest economic importance of any in the South Atlantic and Gulf States, ranks second among American pines. It is found in the sandy and gravelly soil from near Norfolk, Virginia, in a belt about 125 miles wide to Louisiana, following the contour of the coast, and is readily distinguished by its long leaves, 9 to 15 inches long, and its cones, which are rather larger than those of other species which accompany it. The average height of the mature tree is about 100 feet, with a diameter of from 2 to 3 feet, tapering very gradually. The wood is

heavier and stronger than that of any other pine upon the market. The layer of sap-wood is rather thin and the heart-wood is prominently marked by the annual rings. The timber is used in all kinds of building, being especially adapted to ship-carpentry, bridge-building, flooring, etc. Large quantities are annually exported, while the building operations of the Southern States are almost wholly dependent upon it. The tree is very resinous, and wherever the sap-wood is laid bare there is an abundant flow of resin, which is largely used in the manufacture of naval stores, turpentine, resin, pitch, tar, etc. The industry ranks second only to the lumber interests. The leaves are utilized for the production by distillation of an oil closely resembling the oil of turpentine, and for the production of pine wool, made by boiling with alkalis, the resulting fibre being used in upholstering.

Two species associated with the Georgia pine in its lower limits are the Cuban pine (*Pinus heterophylla*), very similar to the Georgia pine in size and manner of growth, but considered

LOBLOLLY OR OLD FIELD PINE (*Pinus Tæda*).

somewhat less valuable, and the loblolly or old field pine (*Pinus Tæda*). The loblolly pine springs up in abandoned fields, soon affording a supply of timber and wood for fuel, the quality of which varies widely with the conditions under which it is grown, approaching the long-leaved pine in quality when grown in the forest, but considered inferior when grown in open fields. Another valuable species of the Southern and Eastern States is the short-leaved pine (*Pinus echinata*, or *Pinus mitis*, as it is frequently called), a tree which attains a height of 75 to 120 feet with a diameter of about 2 feet, and which ranges from New Jersey and Pennsylvania through southern Illinois to Arkansas and eastern Texas, in some places occurring in almost pure forests. The wood is heavy, hard, coarse-grained, but strong, and is largely used for the framework of buildings, weather-boarding, railway ties, car and other building. It is less resinous than the long-leaved pine, but in importance ranks next to that species in the South. The jack pine or scrub pine of the

Northern States is *Pinus divaricata* or *Pinus Banksiana*. It abounds from New Brunswick to the Mackenzie River and southward about the Great Lakes, furnishing the cover to the extensive pine barrens of that region, especially in Michigan. It is of little value except for fuel. Next to the white pine perhaps the most valuable species in the North is the red or Norway pine (*Pinus resinosa*), which is found from the Gulf of Saint Lawrence to Manitoba and south to Minnesota and Pennsylvania. It occurs as trees 60 to 100 feet tall and 2 feet in diameter, often forming extensive forests upon dry sandy soils. The wood is light, hard, elastic, resinous, and durable except when in contact with the ground. Its uses are similar to those of the short-leaved pine farther south. The Northern pitch pine (*Pinus rigida*), which occurs throughout the northeastern portion of the United States and adjacent Canada, is of little value except for fuel and charcoal, but, although rich in resin, it is little used, the Georgia pine having control of the market.

Among the important species of the Pacific region may be mentioned the sugar pine (*Pinus Lambertiana*) and the bull pine (*Pinus ponderosa*). The former is one of the largest of the genus, the trees attaining a height of 150 to 300 feet and more than 10 feet in diameter. It occurs through Oregon and California. The tree trunks are straight and without branches for a considerable portion of their height. The timber is of excellent quality, solid, straight-grained, does not warp, and is easily worked, so that it is in demand for finishing lumber and cabinet work. The tree exudes a resin which when burned has a sugar-like flavor, hence the name. The seeds of this and many other species of Western pines are eaten in considerable quantities as nuts. The bull pine, which has several well-marked varieties of diverse utility, is found from the Rocky Mountains to the Pacific Coast, where it attains a height of 100 to 150 feet and a diameter of 5 to 6 feet; occasional trees are found 250 feet high and 10 feet in diameter, but it is rather smaller in the Rocky Mountain region. In the Pacific Coast region the timber is heavy, hard, strong, and fine-grained; farther inland it is coarser-grained, harder, and more brittle. In the southwestern part of the United States are four species known as Piñon pines (*Pinus parryana*, *Pinus cembroides*, *Pinus monophylla*, and *Pinus edulis*). The various species found from Colorado and Utah to Texas and California are chiefly known for their large edible seeds called piñons. These are eaten as nuts (q.v.). The trees are for the most part small and of little value except for their seeds and for fuel. Among the Mexican species of pines the most valuable and interesting are *Pinus Ayacahuite* and *Pinus Montezumæ*, trees of considerable size, the former somewhat resembling the white pine of the United States.

In Europe the most valuable as well as the most widely distributed species are *Pinus sylvestris*, *Pinus Laricio*, and *Pinus halepensis*.

The Scotch pine or Scotch fir (*Pinus sylvestris*) occurs in immense forests sometimes mixed with spruce fir in some European countries, and is the only species indigenous to Great Britain. It attains a height of 80 to 100 feet and a diameter of from 2 to 4 feet, and is frequently

seen with very large branches resembling trunks. It is of quick growth and has been known to attain the age of 400 years. Its very resinous and durable timber, known as red deal and red pine, is highly valued, being used in house and ship carpentry. There is great difference, however, in the timber grown in different soils and situations, inferior white, soft, and comparatively worthless grades being produced in rich soils and sheltered situations. Several varieties yield very superior timber. The Scotch pine is valuable also on account of its turpentine, tar, pitch, and resin. Oil of turpentine is sometimes distilled from the cones, and the leaves, which last have also been used in Germany for the manufacture of a tow-like substance called *wald-volle* (forest wool), suitable for stuffing cushions, etc.

The black or Corsican pine or black fir (*Pinus Laricio*), a native of Austria, but found throughout Southern Europe, is another species closely allied to the Scotch pine. It is remarkable for its very long leaves and its content of resin, which is more abundant than in any other European tree. It often attains a height of 140 feet upon sandy soils, and has been employed to prevent sand drifting. Its timber is of little value, but a great part of the turpentine of the maritime districts of France is obtained from it. It yields also part of the Burgundy pitch in the market. The Aleppo pine (*Pinus halepensis*), a native of the south of Europe, Syria, etc., is a very graceful tree of moderate size, with slender leaves in pairs. It yields a liquid resin or turpentine, which is extracted from it in Provence and elsewhere, and sold as Venice turpentine. The wood is extensively used in the Levant for ship-building. The pinaster or cluster pine (*Pinus Pinaster*) is another important European species. It is found on the shores of the Mediterranean, and also in the Himalayas and in China. Like the black fir, it has been largely used in France for covering waste sandy tracts. The timber is of inferior quality, but it yields large quantities of resin and Bordeaux turpentine.

The stone pine (*Pinus Pinca*), a tree with a broad umbrella-shaped head, forms a characteristic feature of the scenery of the Mediterranean, and is very often introduced in paintings. It is the pinie of the Germans, the *pignon* of the French. The seeds, which do not ripen till the fourth year, are large, abound in a fixed oil, and when fresh have a sweet taste resembling that of almonds, like which they are used in Italy and other countries. Their use, however, is almost entirely confined to the countries in which they are produced, as they very soon become rancid. The wood is useful and beautiful. The Cembra pine or Swiss pine (*Pinus Cembra*), which grows in the central parts of Europe and the south of Siberia, is a stately tree, with more persistent lower branches than in most pines. It has rigid leaves in groups of three to five and produces edible seeds (cembra nuts), which, although extracted with difficulty, are much used in Siberia, this fruit being so much prized that trees are often cut down to obtain it. The cembra pine yields a pellucid, whitish oil, resembling oil of turpentine, and known as Carpathian balsam. The Himalaya mountains abound in pines, some of which rival in magnificence those of North-west America. The Bhotan pine (*Pinus excelsa*),

PINES

3. BARK OF BULL PINE (*Pinus ponderosa*),
4. BULL PINE (*Pinus ponderosa*).

much resembling the white pine in botanical characters, and attaining a height of 90 to 120 feet, abounds in Bhotan, but is not found in the neighboring countries of Sikkim and Nepal. The wood is durable, close-grained, and so resinous as to be used for flambeaux and candles. The cheer pine (*Pinus longifolia*) of India, where it is often cultivated as an ornamental tree, is of graceful appearance. It is abundant on the crests of hills in the lower Himalayas, growing at a lower elevation than other pines. It is much valued for its resin, and the wood is used in India as a substitute for European deal. Of the European species introduced into the United States, the Scotch pine has proved best adapted to the climate and soils. It is frequently planted as an ornamental. *Pinus Laricio* has been introduced into the United States, and its variety *austriaca*, known as the Austrian pine, appears especially adapted to the prairie regions. The dwarf pine (*Pinus Pumilio*) is an alpine species whose stems are usually prostrate.

PINE, JOHN (1690-1756). An English engraver, born in London. He was probably a pupil of Picart of Amsterdam, as his style resembles that master's. He was an intimate friend of Hogarth, who painted him in "The Gates of Calais." Pine's most important works were: "The Ceremonies of the Order of the Bath" (1730); a facsimile of the Magna Charta (1733); a famous edition of Horace with the text engraved throughout, and illustrations from the antique and from Italian scenery (1733-37); *The Tapestry Hangings of the House of Lords* (1739), a work of especial value, as the tapestries were afterwards burned; and a *Plan of London* (1746 and 1755).

PINE, ROBERT EDGE (1730 or 1742-90). An English portrait painter, born in London. He was the son of John Pine, the engraver, and probably his pupil. It is not known whether he had other instruction. After winning a prize with his "Surrender of Calais" and "Canute Reproving His Courtiers," he painted several portraits, such as those of George II., of the Duke of Northumberland, and of Garrick (in the National Portrait Gallery), and a series of scenes from Shakespeare, some of which afterwards appeared in Boydell's *Shakespeare*. About 1783 he came to America and settled in Philadelphia. His intention was to depict some events in the American Revolution, with portraits studied from life, but his time was completely taken up with portraiture. In this line his works include portraits of General Gates, Charles Carroll, Baron Steuben, Robert Morris, George Read, Thomas Stone, and Washington (1785). The latter was engraved for Irving's *Life of Washington*; but although valuable from an historic standpoint, it is not an impressive canvas, as the modeling is weak and he missed the personality of his sitter. After Pine's death many of his pictures were collected in the Columbian Museum in Boston, since burned. Consult Tuckerman, *Book of the Artists* (New York, 1867).

PINEAL BODY (from Lat. *pinæa*, pine-cone, from *pinus*, pine), or **PINEALIS**. The pineal body, improperly called pineal 'gland' and most properly known as the epiphysis, is an unpaired, upward and forward outgrowth of the 'twixt-brain

of vertebrates. It appears as a small, ovoid, conical body of a reddish color, projecting downward and backward between the anterior pair of corpora quadrigemina. Its function is not known, but it is regarded as a rudimentary sense-organ and probably an eye. In many fossil mammals and reptiles there occurs a depression or hollow in the parietal bone known as the parietal foramen, which is thought to have contained such an eye. This view is supported by the fact that in some lizards, and especially in the New Zealand sphenodon (see *TUATARA*), a parietal organ of this kind is well developed, although it lies beneath the skin and is doubtfully functional. Where the parietal eye is thus developed, it is connected with the brain by a special nerve, and both are formed from the epiphysis. In other cases, where there is no parietal eye, the epiphysis is frequently quite short and is sometimes hollow, the cavity being known as the pineal ventricle.

PINEAPPLE (AS. *pinæppel*, from *pîn*, pine + *æppel*, apple). The fruit of *Ananas sativus*, the pineapple plant, which grows from 2 to 4 feet high, producing a single axis to which are attached long, stiff, rough-edged, sword-shaped leaves. The individual plant produces only a single very fragrant and palatable fruit, which varies greatly in size, 4 to 5 inches being the usual diameters and 6 to 10 inches the prevailing lengths of ordinary market specimens. Very large specimens may weigh 15 to 20 pounds. The pineapple is a native of tropical America, and is widely grown in warm climates. Formerly it was an important European greenhouse crop, and the fruits thus produced were of superior quality, but with the improvement of transportation facilities less attention is given to its culture under glass than formerly. The West Indies, Bahama Islands, Florida, Azore Islands, and parts of Northern Africa are the principal regions of production for European and American markets.

PINEAPPLE (*Ananas sativus*).

Queensland supplies the Australian market. In 1899, 14,699,931 plants were growing in Florida, California, and Hawaii. Statistics for other countries are not at hand, but the production is increasing each year. The pineapple succeeds only in regions where frosts do not occur. A climate having an alternate wet and dry season, with a mean annual temperature of 75° to 80° F., appears most favorable. In Queensland the best pineapples are grown in localities having a mean less than 70°. The plant requires a porous, well-drained soil, otherwise it thrives on a great va-

riety of soils. In Florida the best pineapples are grown on a fine sandy soil, analyzing 94 to 99 per cent. silica, and on such soils heavy fertilizing is necessary. Pineapples rarely produce seed. They are propagated commercially by setting out the crown at the top of the fruit, slips from the base of the fruit, suckers from near the base of the stalk, and ratoons from the roots. Suckers are most commonly planted, since these usually produce a crop of fruit in from 14 to 18 months. Crowns or slips require a year longer to come into bearing. The plants are set in rows about 3 feet apart and 18 to 36 inches distant in the row. Once established a pineapple plantation will endure 8 to 10 years without resetting, suckers replacing the old plants. Little cultivation other than the scuffle hoe is required. Within recent years pineapples have been grown extensively in Florida under sheds. These sheds are built of lath spaced 2 or 3 inches apart and nailed to a light framework 6 to 7 feet high. They protect the plants from frost and excessive heat and greatly improve the quality of the fruit. The cost of putting them up prohibits their use except for the finest varieties. For an account of the greenhouse cultivation of pineapples, consult: Thompson, *Gardners' Assistant* (new ed., Watson, vol. v., London, 1902). For outdoor methods and growing under sheds, consult: Rolfs, *Pineapple Growing* (United States Department of Agriculture, Farmers' Bulletin 140, 1901); id., *Pineapple Fertilizers* (Florida Agricultural Export Station, Bulletin 50).

PINEAPPLE FAMILY. A natural order of plants. See BROMELIACEÆ.

PINE BLUFF. A city and the county-seat of Jefferson County, Ark., 42 miles south by east of Little Rock, on the Arkansas River, and at the junction of the Saint Louis Southwestern and the Saint Louis, Iron Mountain and Southern railroads (Map: Arkansas, D 3). It is the seat of the State Colored Normal College. Among other fine edifices are Merrill Institute with a gymnasium, free library, etc., the opera house, the court house, and fraternal society buildings. The State Fair Association holds annual fairs here. The centre of a fertile agricultural section largely interested in cotton-growing, Pine Bluff is an important commercial and manufacturing city. It carries on an extensive cotton and lumber trade, and has large wholesale interests. Its industrial plants include railroad shops of the Saint Louis Southwestern, cotton compresses, cottonseed oil and meal mills, boiler and sheet iron works, a foundry, large printing establishments, feed mills, large lumber and stave mills, a furniture factory, etc. Population, in 1890, 9952; in 1900, 11,496.

PINE FINCH, LINNET, or SISKIN. A small North American finch (*Spinus pinus*) closely related to the goldfinch. The upper parts are variegated black and buffy; the under parts white, tinged with buff and heavily streaked with black. It is found throughout North America, wintering as far south as the Gulf and breeding mostly north of the United States, but is erratic in its movements, being abundant some winters and then not seen again for several years. The nest is built in coniferous trees, of twigs and rootlets, and is lined with down and hairs. The eggs are usually four in number, bluish white,

thinly spotted with reddish brown. The pine finch feeds on seeds and buds, and resembles the goldfinch in habits, but is less sprightly and its notes are less musical. In England the pine grosbeak is often called pine finch. See GROS-BEAK.

PINE GROSBEAK. A large finch (*Pinicola enucleator*) of Northern North America, which visits the United States in winter. In general color the male is mottled rose-red above, and ashy on the under surfaces, with two white bands across the wing. The female is ashy-gray, with yellowish-brown on crown and rump. This bird lives in the evergreen forests, and feeds on the seeds of the pine and spruce. See Plate of BUNTINGS AND GROSBEAKS.

PINE GROUSE. One of the names of the blue or dusky grouse of Western America (*Dendragapus obscurus*). See GROUSE.

PINE INSECTS. The insect fauna of the pine is very extensive. In Europe nearly 300 species are found upon trees of the genus *Pinus*, and all but about 20 feed upon different portions of the tree. In the United States nearly 200 have been recorded, but the total number will probably prove to be nearly double that number. Of the pine insects known in the United States prior to 1890 the species which had occasioned locally the most direct and perceptible injury was the pine moth of Nantucket, but the most widely destructive kinds were the timber borers, and of those the larva of *Monohammus confusor*, known as 'the sawyer' in the Southern pine districts, did the most damage. Next to that insect, the white pine weevil (*Pissodes strobi*) does the most damage to timber, since it deforms the trees, causing the growth of gnarled, many-headed trees which except for these attacks would have grown straight and fitted for masts or for the best timber. Some pine-borers are noted for their longevity, and may live for years in articles of furniture or in the timbers of houses, if for some cause prevented from pairing and laying their eggs. Much damage has been done in different parts of the United States by bark-boring beetles of the family Scolytidæ, and especially by the species of the genus *Dendroctonus*, which also seriously affect spruce. The pine-destroying beetle of the Black Hills (*Dendroctonus ponderosa*) has done within recent years an enormous amount of damage to the rock pine in the Black Hills region, bringing about not only a great loss to the owners of the timber, but also to the mining interests of that region, from the lessening of the timber supply. The principal attack seems to be made in August, when the beetles migrate in swarms from the dying trees and settle on the living ones, which they attack and infest in large numbers from near the base to the upper part of the main trunk or stem. Remedial work is largely a part of forest management, and includes a careful consideration of the proper date for cutting.

The wood-engraver bark-beetle (*Xyleborus ætatus*) is the most common and most pernicious of the insects affecting the forests of white pine in the State of New York, and of the yellow pine in the more southern States. *Xyleborus pubescens* feeds mainly under the bark of *Pinus inalls-graphus* works in the pitch pine and to a lesser

extent in the white pine. There are perhaps 20 more species of scolytid bark-beetles which have similar habits in connection with pine trees. Of the flat-headed borers of the family Buprestidae about 20 have been found to attack the pine, while rather more than 20 longicorn beetles of the family Cerambycidae live in the larval state in the wood of the trees of this genus. The white pine weevil (*Pissodes strobi*) lays its eggs in the bark of the topmost shoot of young trees. The larvæ mine in the wood and pith, causing the shoot to wither and die, thereby occasioning a crook or fork in the body of the tree at this point. It is fatal to the growth of these trees, and no competent remedy has been discovered.

The pine moth of Nantucket (*Retinia frustрана*), referred to above, causes the death of pine trees in large numbers. The moth lays its eggs on the twigs and the young larva burrows into the wood, ultimately causing the death of the trees. Many insects affect the leaves of pine, including about a dozen sawflies. In the Northwest a butterfly (*Pieris menapia*) lays its eggs upon pine, and the larvæ destroy the leaves. Another butterfly (*Thecla Nippon*) does similar work on the pines in Florida and Georgia. Two of the hawk-moths, *Lipara Combycoides* and *Lipara pinetum*, feed in the larval state upon pine foliage; and the larva of the imperial moth (*Eacles imperialis*) has similar habits. Many other caterpillars are also to be found doing similar work. The larva of a curious little tineid moth (*Gelechia pinifoliella*) mines in the pine-needles, and the larva of one of the gall-midges (*Diplosis resinicola*) lives in the pitch which exudes from injuries to the pitch pine. Another gall-midge (*Diplosis pini-rigidae*) makes small galls at the bases of the needle clumps. Several plant-lice and scale insects also feed upon the pine, the most notable being the pine-leaf chermes (*Chermes pinifoliae*) and the pine-leaf scale insect (*Mytilaspis pinifoliae*), the latter frequently covering pine needles in various parts of the United States with its minute white scales.

Consult: Packard, *Report on Insects Injurious to Forests* (Department of Agriculture, Washington, 1890); Hopkins, *Insect Enemies of the Pine in the Black Hills Forest Reserve* (ib., 1902).

PINEL, pé'nél', PHILIPPE (1745-1826). A French physician; born at Saint André, in the Department of Tarn. After receiving a classical training at the College of Lavour, he studied medicine at Toulouse, taking his degree in 1773. He continued his medical studies at Montpellier, and in 1778 removed to Paris. He applied himself to the study of mental aberration, obtained a prize for his book on the subject, and was appointed physician of the Bicêtre (1792) and of the Salpêtrière (a similar asylum, for females) in 1795. In these institutions he won fame by recognizing insanity as a disease and replacing the old barbarous methods of treatment with kinder and more humane methods. In the Salpêtrière Pinel inaugurated the scientific study of insanity by commencing a class of clinical medicine, which he continued after his appointment to the chair of medical physics and hygiene, and subsequently to that of pathology, at the School of Medicine in Paris. He was admitted as a member of the Institute in 1803. His most valuable works are the *Traité medico-philoso-*

sophie sur l'alienation mentale (1801) and *La nosographie philosophique* (1798), with its commentary, *La médecine clinique* (1802).

PINE LINNET, or SISKIN. See PINE FINCH.

PINELO, pé-nā'lo, ANTONIO DE LEON. See LEON PINELO.

PINE MARTEN. The American marten (*Mustela martes*). See MARTEN, and Plate of FUR-BEARING ANIMALS.

PINE MOUSE. An American meadow-mouse (*Microtus pinctorum*), rusty brown in general color, and distinguished by its long, silky, mole-like fur. It is more subterranean in its habits than others of our mice, and frequently makes long tunnels under the surface, showing raised roofs like those of the moles. It is especially numerous in the pine-wood districts of the Southern States, but also ranges north into Southern New England and westward throughout the Lower Mississippi Valley. Consult Stone and Cram, *American Animals* (New York, 1902).

PIN'ERO, ARTHUR WING (1855—). An English dramatist. He was born in London, on May 24, 1855, of Jewish ancestry on his father's side. He began his studies with a view to the practice of law, which he abandoned, however, and made his appearance as an actor at Edinburgh in 1874. Subsequently he was a member of the Lyceum company, and obtained under Henry Irving a practical experience in stagecraft which was of great value to him. About 1876 he made, with *Tico Can Play at That Game*, his first attempt at play-writing, to which after 1881 he devoted himself. His comedietta *Tico Hundred a Year* was produced at the Globe Theatre in 1877. In the long list of his later plays, which have been for the most part very successful, are: *The Money Spinner* (1880); *The Squire* (1881); *Lords and Commons* (1883); *The Rocket* (1883); *The Magistrate* (1885; published, London, 1892); *The Schoolmistress* (1886; published 1894); *The Hobby Horse* (1886; published 1892); *Dandy Dick* (1887; published 1893); *Sweet Lavender* (1888; published 1893); *The Weaker Sex* (1888; published 1894); *The Profligate* (1889; published 1891); *The Cabinet Minister* (1890; published 1892); *Lady Bountiful* (1891; published 1892); *The Amazons* (1893; published 1895); *The Second Mrs. Tanqueray* (1893; published 1895); *The Notorious Mrs. Ebbsmith* (1895; published 1895); *The Benefit of the Doubt* (1895; published 1895); *The Princess and the Butterfly* (1897; published 1898); *Trelawney of the "Wells"* (1898; published 1899); *The Gay Lord Quex* (1899; published 1900); *Iris* (1901; published 1902). Of his earlier pieces the most popular was perhaps the domestic drama called *Sweet Lavender*. Pinero's greatest work, however, is considered to be *The Second Mrs. Tanqueray*, about which the battle of the critics has been waged over the fundamental questions of the problem play of modern society. Its cleverness and dramatic force make it an admirable example of its kind.

PINEROLO, pé'nā-rō'lo (Fr. *Pignerol*). A town in the Province of Turin, Italy, situated on a hill on the left bank of the Chisone, 22 miles southwest of Turin by rail (Map: Italy, B 3). It has an eleventh-century cathedral, a lyceum, a gymnasium, a technical institute, and a the-

atre. There are manufactures of woollens, cottons, silks, leather, and paper, and a trade in grain, wine, cattle, fruit, and lumber. Population (commune), in 1881, 17,039; in 1901, 18,250. Originally a possession of a local Benedictine abbey, Pinerolo passed to the House of Savoy in 1188 and later became a residence city. It was taken by the French in 1536 and in 1631, when it was strongly fortified, its castle was the prison for the Man with the Iron Mask, Fouquet and Lauzun. Pinerolo was returned to Savoy in 1696 and its fortifications were demolished in accordance with the Treaty of Utrecht.

PINES, ISLE OF. An island south of Cuba. See ISLE OF PINES.

PINES, ISLE OF. A small island in Melanesia, situated near the southern extremity of New Caledonia (q.v.), of which it is a dependency. It has an area of 58 square miles, is mostly barren, except along the coast, and has a population, exclusive of convicts, of about 600 New Caledonians and a few European settlers. Since 1872 it has been a French penal station.

PINE SNAKE, or BULL SNAKE. A large robust colubrine serpent (*Pityophis melanoleucus*) of the southerly half of the United States, often exceeding six feet in length, and glistening creamy white, blotched with dark brown. It derives its name from the pine lands in which it is found, emits a strong disagreeable odor, and feeds on eggs, birds, and small mammals. It is harmless, but makes a loud hissing and sometimes even bellowing noise, when disturbed, to which fact it owes its name 'bull snake'; but why it should also be called 'thunder-and-light-

HEAD OF PINE SNAKE.

Showing formation of glottis: a, sheath of tongue; b, epiglottis; c, glottis.

ning snake' is not so easily explained. Three or four similar species and varieties inhabit dry, sandy regions, throughout the interior of the country, especially in the Southwest and in Mexico. These are brighter in color than is the Eastern species. Consult: Cope, *Crocodilians, Lizards, and Snakes* (Washington, 1900); Lockwood, "The Pine Snake," in *American Naturalist*, vol. ix. (Boston, 1874); Abbott, *A Naturalist's Rambles* (New York, 1884).

PINE SWIFT. The name in the Northern coast States of the 'fence-lizard' (*Sceloporus undulatus*). (See ALLIGATOR LIZARD; FENCE LIZARD.) It is very common in the pine woods from New Jersey southward. It is entirely harmless, and has many most pleasing ways.

PINE-TREE FLAG. A flag used in the Massachusetts Colony as early as 1700, at first red or blue with a pine-tree on the white field,

and later white bearing a pine-tree in the middle and the motto, "An Appeal to Heaven." This was the flag carried by the first war-vessels commissioned by Washington at the beginning of the Revolution.

PINE-TREE MONEY. Money coined in Massachusetts from 1652 to 1682, in the values of a shilling, sixpence, and threepence, so called from the rude figure of a pine-tree on one face, while the other bore "New England," with the date. The name 'Boston' or 'Bay' shilling was first used, being changed to 'Pine-tree' in 1680.

PINE-TREE STATE. Maine. See STATES, POPULAR NAMES OF.

PINEY DAMMAR. See DAMMAR.

PINEY-TREE. An East Indian tree. See CALOPHYLLUM.

PINEY VARNISH. See DAMMAR.

PING-PONG. A modified form of lawn tennis (q.v.) played on a table marked to scale, after the model of a full-sized lawn-tennis court. The bat is usually covered with a thin skin like a battledore, but resembles a lawn-tennis racket in shape, while the ball is generally made of light celluloid. The name ping-pong is a registered trade-mark, the game itself being by many attributed to an Englishman, James Gibb, who in 1891 called public attention to it, under the title 'gossima.' In 1900 the name was changed to ping-pong, and under that title enjoyed its greatest vogue. It spread to France and America, where for a short season it was very popular. Any kind of table may be utilized, but its size should not be less than 5 feet 6 inches by about 3 feet, nor larger than 10 × 5. The regulation table is 9 × 5, the height of the net, which is stretched across the middle of the table, being regulated at the ratio of three-fourths of an inch for every foot in the length of the table. The game is for two players standing one at each end of the table. The player who first delivers the ball is called the server and the other the striker out. At the end of each game the striker out becomes the server and vice versa. The service is strictly underhand, delivered from behind the end of the table. The ball served must drop on the table top anywhere beyond the net, and is then in play. If it drops into the net, or off the table, it counts to the striker out. There is no second service as in lawn tennis, but the system of scoring is the same as in that game. Consult Parker, *Ping Pong* (New York, 1902).

PIN'GREE, HAZEN SENTER (1842-1901). An American politician, born in Denmark, Maine, the son of a poor farmer. He worked in a cotton factory at Saco, and in 1860 entered a shoe factory at Hopkinton, Mass., whence he enlisted in 1862 in the First Massachusetts Heavy Artillery. He was captured by Mosby in 1864 and imprisoned at Andersonville for a few months. In 1865 he settled in Detroit and started the shoe firm of Pingree & Smith. In 1889 he was elected Mayor of the city on the Republican ticket, and served four terms. In 1896 he got control of the Republican State organization and was elected Governor, and held that office until 1900.

PING'-YANG' (Korean *P'yŏng*-, *Phyŏng*-, or *P'yŏng-Yang*). A walled city of Korea, capital of the Province of South Phyŏng-an, and the

most important city in the country after Hanyang Pu, the Seoul or capital (Map: Korea, G 4). It stands in an undulating plain on the right bank of the Ta-tong River, about 36 miles above its mouth. Its walls are 20 feet high, run parallel with the river for about 2½ miles, and are loop-holed and battlemented and pierced with several gates with imposing towers. The streets are laid out at right angles. P'ing-yang is the most ancient city of Korea, Ki-ja (see KI-TSE), the reputed founder of Korean civilization, having landed here some time after B.C. 1122. The superstitious notion is held by Koreans that the city is boat-shaped (representing the craft on which Ki-ja arrived from China) and that it is the height of good sense not to sink wells within the city lest the vessel be scuttled. The water supply of the inhabitants is, therefore, carried in from outside. Two large stone posts about 1½ miles above the town are supposed to be the mooring posts. The tomb of Ki-ja is one of the sights of the city. P'ing-yang is open to foreigners, and much successful missionary and educational work is carried on.

The city is regarded as the military key to Korea, and in consequence it has suffered much from war. A great battle was fought here in 1593 between the Chinese troops sent to succor Korea during Hideyoshi's invasion and the Japanese troops under Konishi; and the principal battle of the Japanese-Korea-Chinese War of 1894-95 was fought here September 16, 1894, resulting in the utter defeat of the Chinese, who lost 4000 men. A handsome stone monument in memory of the Chinese General Tso, who led the cavalry, has been erected on the spot where he died, and on a lofty knoll within the city is a monolith erected by the Japanese to their dead.

PINK (from *pink*, to puncture, to pierce; so called from the jagged edges of the petals). *Dianthus*. A genus of about 70 annual and perennial plants of the natural order Caryophyllaceae, chiefly natives of Europe and the temperate parts of Asia. Their beautiful and often fragrant solitary or clustered flowers are borne at the ends of the branches, and have attracted admiration in all ages, some of the species having been long cultivated in gardens. Their cultivation has given rise to many varieties, including single and double forms of many different colors. The species *Dianthus Caryophyllus*, including the well-known and widely cultivated carnation (q.v.), clove pink, picotee, or grenadine, is native to Southern Europe, where it is found growing wild on rocks and old walls. The common pink, also called feather pink (*Dianthus plumarius*), is the parent species of many cultivated forms. This has always been a favorite ornamental plant on account of its hardiness and the beauty and fragrance of its blossoms. It differs from the foregoing species in having rough-margined leaves and fringed petals. Nearly allied to the common pink is *Dianthus superbus*, found in moist places in some parts of Europe and often grown in flower-borders. The maiden pink (*Dianthus deltoides*) is a low growing perennial frequently cultivated for its dense masses of leaves and flowers. The China or Indian pink (*Dianthus chinensis*) has long been in cultivation and numerous dwarf and double and single flowered varieties of many varied colors have been developed. The sweet William, or bunch pink (*Di-*

anthus barbatus), is a popular species of easy cultivation and abounds in country gardens. Its flowers are crowded into dense flat clusters at the top of the stem. The varieties are exceedingly numerous and include many highly developed forms. The Deptford pink (*Dianthus Armeria*) is a small European species which has become

PINK (*Dianthus plumarius*).

naturalized in the Eastern United States. Pinks prefer a rather light sandy loam soil. They are propagated from seeds and from cuttings. If the plants are to flower the same season the seeds are sown in heat during February, transplanted when the plants are large enough, and hardened gradually to cool culture until May, when they are set out. Seeds sown in the open during summer produce plants which blossom the following year. The young plants of outdoor sowings are also transplanted as soon as they become crowded and finally transferred to their flowering position in fall. Many varieties of pinks are grown as greenhouse plants, and these are generally increased by layers or cuttings.

PINKERTON, ALLAN (1819-84). A Scottish-American detective, born in Glasgow, Scotland. In 1842 he emigrated to America to escape punishment for his part in the Chartist Movement, and soon afterwards settled in Chicago, where he opened a detective agency. Before the outbreak of the Civil War he had become widely known, and in 1861 he guarded President Lincoln during the latter's journey to Washington for the inauguration. Soon afterwards he was commissioned to organize the Federal Secret Service Department, of which he was made the head. During all this time he continued his private detective agency in Chicago, and established branch agencies in other important cities. When the changed industrial conditions that followed the war led to strikes and violence, he organized a force of armed men which he hired to employers and corporations for the protection of their property. This mercenary force, known as 'Pinkerton's Men,' played a conspicuous part in some of the most important labor disturbances of the last quarter century, notably in the suppression of the Molly Maguires (q.v.)

and in the Homestead strike. Among other well-known cases with which Pinkerton was connected were the capture of the robbers who took \$700,000 from the Adams Express Company's safe on a New York, New Haven and Hartford Railroad train, on January 6, 1866, and the dispersion of a gang of murderers who for a number of years terrorized all southern Indiana. He wrote several books on subjects connected with his work, among them: *The Molly Maguires and the Detectives* (1877); *Criminal Reminiscences* (1878); *The Spy of the Rebellion* (1883); *Thirty Years a Detective* (1884); and *History and Evidences of the Passage of Abraham Lincoln from Harrisburgh, Pa., to Washington, D. C., on the 22d and 23d of February, 1861* (1891).

PINKERTON, JOHN (1758-1826). A Scottish antiquary and author, born in Edinburgh, February 17, 1758. He was educated at the grammar school of Lanark; articled to a writer to the signet in Edinburgh; abandoned law for literature; settled in London (1781); and resided during his last years in Paris, where he died, March 10, 1826. Among his numerous publications are: *Rimes*, a volume of verse (1781); *Select Scottish Ballads*, professing to be ancient (1783); *Essay on Medals* (1784); *Letters of Literature* (1785); *Ancient Scottish Poems Never Before in Print, from the Manuscript Collection of Sir R. Maitland* (1786); and *The History of Scotland from the Accession of the House of Stuart to that of Mary, with Appendices of Original Documents* (2 vols., 1797). This last work, though valuable for its matter, is disfigured by an attempt to rival the style of Gibbon. Consult his *Literary Correspondence*, edited by Dawson Turner (London, 1830).

PINKEYE, or INFLUENZA. An infectious disease prevalent among horses. It is characterized by high fever, rapid prostration, swelling of the mucous membrane of the eyes, which become red and congested. On account of this condition the disease is called pinkeye. The cause is believed to be a specific bacillus similar to that producing influenza in man. The spread of the disease is also attributed to swarming of frits (q.v.), which get into the eyes of the horses. The treatment is symptomatic. Good food and water, fresh air and sanitary surroundings are of first importance. The heart should be watched carefully and if necessary cardiac stimulants used. The eyes should be bathed with an antiseptic wash.

PINKNEY, PINK'NI, EDWARD COATE (1802-28). An American poet, born in London, England, October 1, 1802. He was the son of William Pinkney, the well-known Maryland lawyer and orator, and was born while the latter was commissioner in England. He served in the navy (1816-24), was admitted to the Baltimore bar in the latter year, was made professor of rhetoric and belles-lettres in the University of Maryland, and edited the *Marylander* (1827); but he is best known for a tiny volume of *Poems* (1825), since highly praised by Poe and others and several times reprinted. Pinkney died in Baltimore, Md., April 11, 1828.

PINKNEY, WILLIAM (1764-1822). An American statesman, born at Annapolis, Md. He was educated at King William's Seminary (afterwards Saint John's College), studied law under Justice Samuel Chase, and was admitted

to the bar in 1786. In 1788 he was a member of the convention to ratify the Federal Constitution, and was elected to the House of Delegates the same year. In 1796 he was appointed a commissioner to England to determine the compensation due American merchants under the Jay Treaty (q.v.), and secured a claim of \$800,000 for Maryland on the Bank of England. He returned to practice law in Baltimore in 1804, and was elected Attorney-General of Maryland in 1805. In 1806 he was sent to England as Minister Extraordinary to treat in conjunction with Minister Monroe regarding the violation of rights of neutrals. On the return of Monroe in 1807 he remained as resident Minister until recalled at his own request in 1811. On his return he was elected to the Maryland State Senate, but was appointed Attorney-General of the United States by President Madison. He commanded a regiment of riflemen during the War of 1812, and was wounded at Bladensburg. He was a member of the national House of Representatives in 1815-16, and in the latter year was appointed Minister to Russia and Special Envoy to Naples. He resigned in 1818 to practice law, and was engaged in many important cases. In 1820 he was elected to the United States Senate, and opposed the admission of Missouri. Consult Wheaton, *Life, Writings, and Speeches of William Pinkney* (1826), which is condensed in vol. vi. of *Sparks's American Biography*. Consult also Pinkney, *Life of William Pinkney* (1853).

PINK ROOT. The root of a species of Spigelia (q.v.).

PIN-MONEY. In law, a sum of money paid periodically by a husband to his wife, to be expended for dress, ornament, and other personal expenses. The origin of the term has never been traced satisfactorily, but writers of some authority assert that it was derived from an ancient tax levied in England for the purpose of supplying the Queen with pins. The practice of providing such an annual sum for the wife's separate use, by means of a marriage settlement, was at one time quite common among the nobility in England. Out of this allowance the wife was supposed to maintain the dignity of her station in the matter of dress, ornament, private benefactions, etc. It was, therefore, intended to be spent and not accumulated. Accordingly, if a husband pays the wife's personal expenses directly, it is a bar to a claim for arrears of pin-money, and, in any event, while the wife continues to cohabit with the husband she cannot collect the arrears for more than one year. However, if she lives separately, all arrears may be collected. If the wife saves anything out of her pin-money while living apart from her husband it becomes her separate property; but if they are living together, such accumulation goes to the husband's representatives on his death, unless he had consented to his wife's saving for her own benefit.

The custom of providing pin-money is no longer common in England, and never gained favor in the United States, although there are some early decisions which apply the English law to such allowances. A weekly or monthly sum paid to the wife for household expenses, etc., does not correspond to pin-money. Sums given to the wife by the husband voluntarily from time to time, when he does not indicate that they are

to be used for a specific purpose, are usually considered as gifts, and become the separate property of the wife. See DOWRY; HUSBAND AND WIFE. Consult the authorities referred to under HUSBAND AND WIFE.

PINNA (Lat. *pinna*, *pina*, from Gk. *πύνα*, *πύνα*, sort of mussel). The popular and generic name of a group of marine mussels with very thin, wedge-shaped shells, tapering to a point at the hinge. The byssus is remarkably long and silky, and by it the species affix themselves to submarine rocks and other bodies, sometimes even to sandy or muddy bottoms. The best-known species is *Pinna nobilis*, of the Mediterranean, the byssus of which was occasionally used by the ancients for fabrics, chiefly as an article of curiosity.

PINNACE (Fr. *pinacc*, *pinasse*, from It. *pinassa*, *pinazza*, pinnace, pine, made of pine, from *pino*, from Lat. *pinus*, pine). Formerly a small two-masted vessel, fitted to be propelled by oars as well as sails, and generally employed as a tender to large ships. The French armed pinnace was usually of 60 to 80 tons, and carried one large 24-pounder and about 100 men. In the United States Navy the term pinnace is not used, but in the British Navy it is still applied to a large carvel-built boat similar to the American sailing launch.

PINNACLE (Lat. *pinnaculum*, diminutive of *pinna*, feather, wing, pin, pen). A termination of tapering form crowning some architectural member. Unknown to ancient art, it was occasionally used in the mediæval Mohammedan and Romanesque styles, but did not become common until the Gothic period, when it became a most important decorative element of architecture. It crowned façade buttresses and flying buttress piers, it filled in the four corners of square towers at the spring of the polygonal spire, it rose as a termination of piers or shafts at gable corners. Groups of pinnacles were sometimes profusely scattered over the roof, as at Milan Cathedral. Pinnacles were square, polygonal, or circular, with spires or gables crowned with finials; they had either an open story or solid masonry with engaged colonnettes and arcades. Sometimes they included a niche containing a statue. The main pinnacles on the buttress piers of Rheims Cathedral are 80 feet high. They are of all sizes, and of the greatest variety of form and decoration.

PINNATED GROUSE. The prairie-chicken. See section on *Prairie Chicken*, under GROUSE.

PIN-NIPE'DIA (Neo-Lat. nom. pl., from Lat. *pinna*, feather, fin + *pes*, foot). A section of Carnivora, comprising seals, otaries, and walruses, in which the fore and hind limbs are short and expanded into broad, webbed swimming paddles. The hind feet are placed very far back, nearly in a line with the axis of the body, and somewhat incorporated with the tail by the integuments. The body is elongated and covered with short fur or hairs, and terminated by a short conical tail. The five toes of each foot are united by the skin and form powerful swimming paddles. The tips of the toes are armed with claws, but they have little power for land locomotion, the typical seals being able only to drag themselves along when out of the water. The

ears are small, often only indicated by apertures, which the animal can close under water. The dentition varies, but teeth of three kinds are always present. The canines are always long and pointed, and the molars have sharp cutting edges.

The pinnipeds include three families, the earless seals (*Phocidæ*), the eared seals or otaries (*Otariidæ*), and the walruses (*Trichechidæ*). The seals differ from the walruses by having incisor teeth in both jaws, and moderate-sized canines, and from the otaries by the absence of ears and inability to use the hind limbs on land. The eared seals, sea-lions, or otaries differ from the typical seals by having small, conical ears, and in the greater use of the limbs, especially the hind limbs, so that they are enabled to execute a sort of walk. Consult: Beddard, *Mammalia* (London, 1902); Allen, *Monograph of North American Pinnipeds* (Washington, 1880). See SEAL; WALRUS.

PINNULE (from Lat. *pinnula*, diminutive of *pinna*, feather, wing, pin, pen). In a pinnately compound leaf, one of the subdivisions of the first divisions or pinnæ. The term has most frequent application among the ferns.

PINOCHLE, pē'nō-k'l' (Ger., of uncertain etymology). A game of cards. Where there are only two players, the game is opened by cutting for deal, which may be according to the highest card, all being high, or by one of the players dealing the cards alternately, one at a time and face upward, the player to whom falls the first ace turned up winning the first deal. Below the ace, the cards decrease in value as follows: Ten, king, queen, knave, nine, eight, and seven. Each player receives eight cards, commencing with the eldest hand, by two and three at a time, after which the seventeenth card is turned up for trump and exposed on the table. Should the card so turned up be a seven, the dealer scores 10 points immediately. The eldest hand begins the game by leading, after which the lead goes to the winner of the preceding trick. After the trick is played each player draws a card from the top of the talon, the winner of the preceding trick first. The drawing is continued after each trick until the talon is finished. The winner of the previous trick must make his announcement before drawing from the talon, only one announcement at a time being permissible. No more announcements can be made after the talon is exhausted, and suit must be followed, with the provision that if a player cannot follow suit, if possible he must play a trump. The face value of the cards is counted at the end of each game, and the points added to the value of the announcements and credited in the score; the winner of the last trick adds ten points additional. All announcements are based on the cards held in hand at the time of announcing. The five highest trumps count 150; four aces 100; four kings 80; four queens 60; four knaves 40; pinochle, or queen of spades and knave of diamonds, 40; king and queen of trumps 40; king and queen of any other suit 20. Seven of trumps counts 10, and, when duly announced for the turned-up card, is exchangeable. In this game 500 points constitute the game, and the player first making that score may throw down his hand and claim the game.

The game above described is the original single pinochle, but the modern and more generally adopted game is played with a specially prepared pinochle pack of cards, or with two packs of cards, of which only the ace, ten, king, queen, knave, ten, and nine of each pack are kept—a total of 48 cards in all. The dealer deals four cards at a time, until each player has twelve, the next or twenty-fifth card being turned up for trump and placed exposed by the side of the undealt cards. The scoring is the same as in the older game, except that 1000 points are game, and the value of announcements as follows: Eight aces 1000; eight kings 800; eight queens 600; eight knaves 400; double pinochle (i.e. two queens of spades and two knaves of diamonds) 300; ace, ten, king, queen, and knave of trumps 150; four aces of different suits 100; four kings of different suits 40; pinochle (i.e. queen of spades and knave of diamonds) 40; king and queen of trumps (styled a royal marriage) 40; king and queen of any suit not trumps (styled a marriage) 20. Generally speaking, the laws of bezique will be found to govern most matters of detail in pinochle.

In the three-handed game, all the cards are dealt by four at a time, the last card being turned up for trumps. Should a nine be turned up, the dealer scores 10 points; but where that does not happen, either of the other players holding a nine of trumps may exchange it for the trump card and claim the 10 points, the eldest hand having precedence. Each player melds or announces whatever he has in hand, but no melded points are added to the score until the player has taken a trick. Four-handed pinochle is played in the same manner as for three players, except that, to prevent the eldest hand getting information which would influence his play, no melds are permitted until he has led a card for the first trick, after which he may announce his melds. Each of the other players must first play to the first trick before declaring the melds.

PIÑON, pēn'yōn. A kind of pine (q.v.).

PINOS, pē'nōs. A town of the State of Zacatecas, Mexico, 65 miles southeast of the capital of the State (Map: Mexico, II 6). It is in the midst of an important mining region, with extensive gold and silver deposits, and manufactures large quantities of mescal. Its municipal population in 1895 was 8183.

PINSK. A district town in the Government of Minsk, Russia, situated in a marshy region on the Pina, about 105 miles east of Brest-Litovsk (Map: Russia, C 4). It has a Roman Catholic church of the fourteenth century, a realschule, and manufactures of matches, lumber, and leather. The commercial importance of the town has greatly decreased since the construction of the Poliessie railways. Population, in 1897, 28,028. Pinsk is mentioned as early as the eleventh century, and was formerly the capital of a separate principality.

PINSUTI, pēn-sōō'té. CIRO (1829-88). An Italian-English teacher of singing and composer, born in Siena. He studied under his father, and played in public at the age of ten. Subsequently he went to England under the auspices of the celebrated Henry Drummond, and studied the piano-forte and composition under Potter and the violin

under Blagrove. In 1845 he entered the Conservatorio di Bologna, where he became Rossini's favorite pupil. In 1848 he returned to England, and gave singing lessons in London and Newcastle. He was also appointed in 1856 professor of singing at the Royal Academy of Music, London. His compositions include several indifferently successful operas, pianoforte pieces, and over two hundred English and Italian songs, choruses, and part songs. His fame chiefly rests upon his songs. In England he was regarded as practically a native composer, largely through his appeal to the national spirit in such songs as "Where are the Boys of the Old Brigade?" He died in Florence.

PINT. See WEIGHTS AND MEASURES.

PINTA. The name of one of the three caravels in which Columbus made his first voyage to America.

PINTA'DO. See PETREL.

PINTAIL, or SPRINGTAIL DUCK. A common, widespread, and highly esteemed duck (*Dafila acuta*), characterized by the long tapering tail of the drake. It is about equal in size to the mallard, but more slender. The head is brown, with a white line on each side extending down the neck; the back and sides marked with wavy lines of black and grayish-white; the lower parts white; the elongated central tail feathers black. It is a native of all the northern parts of the world, migrates southward in winter, and is a regular visitant of many parts of the Atlantic coasts. It also frequents fresh-water lakes and ponds, and is common in winter in the valley of the Mississippi. It breeds from Iowa northward, but chiefly in the interior, and is not known as a summer resident anywhere on the Atlantic coast. Its winter range extends southward to the Mediterranean and the Gulf of Mexico, and even to Africa and the West Indian islands. Consult Baird et al., *Water Birds of North America* (Boston, 1884).

Some other birds having long sharp tails are called 'pintails' by sportsmen, as, especially, one of the European sand-grouse (*Pterocles setarius*).

See PLATE OF EGGS OF WATER AND GAME BIRDS.

PINTO, pēn'tō. See SERPA PINTO.

PINTO, FERNAO MENDES (1509 or 1510-83). A Portuguese traveler and the first white man to visit Japan. He was born at Montemor-o-Velho (Beira). Embarking for the East Indies, his ship was captured by the Turks and he was sold as a slave. According to his own account, his adventures were very wonderful. He spent twenty-one years in Asia and Africa, was thirteen times taken prisoner and seventeen times sold as a slave. While returning in a pirate junk from Cochinchina to China, his vessel was separated from her companions, and after twenty-three days on the open sea he sighted the island of Tane (Tanégashima), one of the Loo-choo islands (q.v.), where the strangers were welcomed and given a house. They surprised the people by their firearms, which the Japanese quickly imitated, making over 600 guns within five and a half months, and on one of his three later visits to Japan Pinto found firearms in a great many places. To this day, among Japanese country folk, a pistol is called Tanégashima. Hokusai (q.v.) pictured Pinto and his companions with their firearms in his albums. Re-

turning to Portugal in 1558, Pinto lived at Court several years and died near Lisbon, July 8, 1583. His posthumous work, *Peregrinação*, appeared at Lisbon in 1614 and was at first supposed to be a sort of Robinson Crusoe romance, but in the main, and apart from personal items, its statements have been confirmed by modern research. An English rendering by Cogan appeared in London in 1663, 1692, and 1891 (*Adventures and Voyages of Ferdinand Mendez Pinto*).

PINTSCH SYSTEM. A process for the production of compressed gas, used chiefly for lighting railway cars. When ordinary coal gas is burned at the pressure of street mains it gives an illumination of about 4 candles to each cubic foot, while oil gas at the same pressure yields about 16 candles to the cubic foot. Compression and storage of gas produce a diminution in illuminating power in consequence of the deposition of the rich oily hydrocarbons. This loss, however, is much less in oil gas than in coal gas. At 125 pounds pressure to the square inch, one foot of oil gas is equal in illuminating power to about five feet of coal gas. The use of oil gas for the purpose of illuminating railway cars is, therefore, much more economical, and the Pintsch system finds extensive use on many of the leading railway lines in the United States. The outfit consists of storage tanks, a pressure regulator, and a system of piping to the lamps, which are of special design, each having from four to six burners arranged beneath a porcelain reflector, the whole being incased in a glass bell-jar.

PINTURICCHIO, pên-tōō-ré'kê-ō (It., little painter) (1454-1513). The name commonly applied to Bernardino di Betto, an Italian painter of the Umbrian school (early Renaissance). He was born at Perugia, where he studied under Fiorenzo di Lorenzo, later reflecting many of the mannerisms of his contemporary Perugino. The latitude of his subjects and the distinctly illustrative and historical character of many of them have rendered him famous as the historical painter of the Umbrian school. Though using the Umbrian forms, which catered to mediæval tradition, Pinturicchio's works reflect the humanistic spirit of the times. They are mainly frescoes, highly decorative in style, and not without charm of color. As compared with Perugino, Pinturicchio lacks character and dramatic vigor; but he is less conscious and does not fatigue by monotony. In 1484 the artist was engaged as assistant to Perugino in fresco work in the Sistine Chapel. The "Adoration of the Shepherds" in Santa Maria del Popolo and decorations in the Palazzo Belvedere and Palazzo di San Apostolo, Rome, were executed before 1491. Between 1491 and 1501 he produced frescoes in the Cathedral of Orvieto; in the Vatican, Rome; the series illustrating the life of San Bernardino, in the Bufalini Chapel, Araceli, Rome; and the "Madonna" in the Perugia Academy. At Spello, near Foligno, he left numerous works by himself and his pupils. In 1502 Cardinal Francesco Piccolomini intrusted to him the decoration of the cathedral library at Siena. These frescoes, depicting the life of Æneas Sylvius Piccolomini (Pope Pius II.), called upon the artist for the display of his talent in ceremonial composition. The commission was completed in 1508, with the aid of many assistants, among whom was Raphael, who came to Siena in 1503.

The late works of Pinturicchio show a haste and carelessness that would tend to substantiate the accusation that his love of gain got the better of his love of art. He died in Siena, December 11, 1513.

Consult: Morelli, *Italian Masters in German Galleries*, translated (London, 1883); Vermiglioli, *Memorie di Bernardino Pinturicchio* (Perugia, 1837); Schmarzon, *Rafaël and Pinturicchio in Siena* (Stuttgart, 1880); id., *Bernardino Pinturicchio in Rome* (ib., 1882); Ehrle and Stevenson, *Gli affreschi del Pinturicchio nell'appartamento Borgia* (Rome, 1897); Steinmann, *Pinturicchio* (Leipzig, 1898); Ricci, *Pinturicchio: His Life, Work, and Time* (London, 1902).

PINUS. A genus of trees. See PINE; CONIFERÆ; GYMNOSPERM.

PINWORM. One of the nematode worms (*Oxyurus vermicularis*) parasitic in the large intestine and rectum of man, especially in children. It is a small white worm, half an inch long or less, and very slender. The females are larger than the males. Unlike many nematodes, the pinworms reproduce directly in their host, and have no alternation of hosts or of generations. The eggs are very minute and must be taken into the body with the food or at least through the mouth, but the exact manner of infection is not really known. The presence of these worms is often a matter of discomfort, but they are rarely so numerous that their presence is a source of danger to the person afflicted.

PINZON, pên-thôn', FRANCISCO MARTIN. A Spanish navigator, brother of Martin Alonso and Vicente Yañez Pinzon (qq.v.). He was pilot of the *Pinta*, on the first voyage of Columbus.

PINZON, MARTIN ALONSO (c.1440-93). A Spanish navigator, companion and patron of Columbus. He was born at Palos and attained distinction as a bold and skillful sailor, making distant and profitable voyages as far as the Guinea Coast. Through Fray Juan Perez de Marchena, prior of the Convent of La Rábida, he came to know Columbus, and his enthusiasm was aroused by the scheme of the great navigator. With his brothers, Vicente Yañez and Francisco Martin, he exerted his influence in the seafaring town of Palos to enlist men for the voyage across the Atlantic. The brothers also lent Columbus the money which he was to contribute as his share of the cost of the expedition. On the first voyage of discovery Martin Alonso commanded the *Pinta*. As the fleet was coasting along Cuba after the landfall on Guanahani Island, he separated from the other two ships in disregard of the Admiral's orders (November 21, 1492). He was the first to discover the island of Haiti, on the coast of which he rejoined Columbus January 6, 1493. He was met with severe reproaches by Columbus, who charged him with treasonable intentions; and indeed there is little doubt that Pinzon was envious of the glory which had fallen to the Genoese and was desirous of linking his own name with some great discovery. On the return voyage Martin Alonso, in the *Pinta*, parted company with the *Niña* during a storm, and reaching Bayona in Galicia, sought to obtain an interview with the Spanish monarchs, who, however, refused to receive in person any one but the Admiral. Pinzon thereupon set sail for Palos, which he reached on the same day as Columbus (March 15th). As the result prob-

ably of privations encountered during the voyage, he died soon after at the Convent of La Rábida. Consult Asensio, *Martin Alonso Pinzón, estudio historico* (Madrid, 1892).

PINZON, VICENTE YAÑEZ (c.1463-c.1519). A companion of Columbus. He was born in Palos, and was a younger brother of Martin Alonso Pinzon (q.v.). Pinzon commanded the *Niña* on the first voyage, and afterwards became the greatest of the seafaring men engaged in discoveries in the New World, down to the time of Magellan. He appears to have made several independent voyages before the close of the century, and it is probable that in 1497 (accompanied perhaps by Vespuceius) he reached the mainland of America (discovering Central America) almost simultaneously with Cabot's landing on the continent. He sailed again on November 18, 1499, returning the following September, after discovering the coast of Brazil and the mouth of the Amazon. In 1505 he was appointed to command an expedition to the Spice Islands, but Portuguese intrigues prevented him from sailing, and instead he was given charge over the fortifications to be erected in Porto Rico. He was also made Governor of the island with authority to colonize it. He was, however, a seaman rather than an administrator, and he spent the next year or two trying to get the command of a fleet, which the Portuguese prevented, as he was suspected of designs against their territories. In June, 1508, he finally got away, with Juan Diaz de Solis. They returned in November, 1509, but no record survives as to where they secured their cargo of gold and other New World products. Consult Harrisse, *Discovery of America* (London, 1892).

PIOMBINO, pé'óm-hé'nó. Formerly an independent principality of Northern Italy, now a part of the Province of Pisa. It belonged to Pisa before 1399, when it became independent under rulers of the House of Appiani. In 1700 it came into the possession of the Buoncompagni. It was incorporated with France in 1801, but from 1805 to 1814 was ruled as a principality by Elisa Bacciochi, the sister of Napoleon. In 1815 it was united with the Duchy of Tuscany.

PIOMBINO. A town in the Province of Pisa, Italy, situated on a promontory projecting into the Tyrrhenian Sea, 40 miles by rail southeast of Leghorn (Map: Italy, E 5). Its ancient walls and ruins of an old castle still remain. The town has a busy harbor, and manufactures ironware and oil. Population (commune), in 1901, 8309. To the north are Etruscan and Roman remains of the town of Populonia, whose site still preserves the ancient name.

PIOMBO, pé-óm'hó, SEBASTIANO DEL. See SEBASTIANO DEL PIOMBO.

PIONEER (Fr. *pionnier*, OF. *peonnier*, foot-soldier, sapper, from OF. *pcon*, *paon*, *pion*, foot-soldier, Fr. *pion*, pawn, from ML. *pedo*, foot-soldier, from Lat. *pes*, foot; ultimately connected with Eng. *foot*). A military mechanic, or laborer. Originally pioneers were ordinary laborers of the country in which the army was operating. Their name was undoubtedly derived from the fact that their principal duty was to prepare the way for the advance of the troops, cutting down trees, building bridges, removing obstacles, etc. They were the forerunners of the modern military

engineer (see ENGINEER CORPS), the engineers or technical troops of Germany being still known as pioneers. In the British Army there are two pioneers to every company of infantry, who collectively are under a pioneer sergeant, a regimental staff non-commissioned officer. Their equipment consists of either a pick, shovel, or axe, and a one-edged, pointed sword, the other edge of which is cut like a saw. Pioneers are the only soldiers allowed to wear beards. On the march, or on occasions of ceremony, they parade with the non-commissioned staff; and in column of route, precede the band. To be a pioneer, a soldier must be a skilled mechanic, and have passed the pioneer instruction course at Chatham. He receives working pay. See ENGINEERING, MILITARY.

PIONEERS, THE. A novel by James Fenimore Cooper (1823). Though the earliest published, it is the last but one in order of the *Leatherstocking Tales*, giving the old age of Natty Bumppo and the death of Chingachgook.

PIORRY, pé'ótré, PIERRE ADOLPHE (1794-1879). A French physician, born in Paris. He was educated there, became doctor of medicine in 1816, and in 1840 was appointed professor of pathology and in 1850 of clinical medicine. He devised a new nomenclature which met with no success and invented the pleximeter for mediate percussion, for which he received the Montyon prize in 1828. He wrote: *De l'hérédité dans les maladies* (1840); *Traité de médecine pratique* (1842-51); and *Traité de plessimétrie* (1866).

PIOTRKOW, pyótr'-kóv. A government of Russian Poland, bounded on the north by the Government of Warsaw. Area, 4735 square miles. The surface is mostly level and somewhat undulating toward the south. Coal and iron are found in some parts of the government and mined to some extent. The chief rivers are the Warta and the Pilica. Although the soil is not well adapted for agriculture, this is the chief industry. Stock-raising is also of some importance. Textiles represent the leading manufacturing industry, of which Lodz and Piotrkow are the two centres in Russian Poland. Population, in 1897, 1,406,951.

PIOTRKOW. The capital of the government of the same name in Russian Poland, situated on the Warsaw-Vienna Railway, about 16 miles southeast of Lodz (Map: Russia, A 4). It has a number of old churches and monasteries, an old castle, two gymnasia, and a fine town hall. The chief manufactures are farm implements and textiles. Population, in 1897, 30,400. Piotrkow is one of the oldest towns of Poland, being mentioned as early as the twelfth century. It was fortified by Casimir the Great and received Magdeburg rights in 1404. It was the scene of frequent diets and in 1577 became the seat of the highest tribunal of Great Poland.

PIOZZI, pé-ót'sé, Mrs. HESTER LYNCH, better known as Mrs. THRALE (1741-1821). A noted friend of Dr. Samuel Johnson. She was born at Bodvel, in Carnarvonshire, Wales. In her girlhood she learned Latin, French, and Italian, wrote for the *Saint James's Chronicle*, and was known among her friends for her cleverness and lively disposition. In 1763 she married Henry Thrale, a well-to-do Southwark brewer, her senior by thirteen years. It was no love match; but except for some flirtations of the husband, the

union was comfortable. Thrale had a house in Southwark and an estate at Streatham, near Croydon. Dr. Johnson became acquainted with Mrs. Thrale in 1764, and for sixteen years spent much time at Streatham Park. He was there usually from Saturday till Monday, and for months—during the summer. The memorable friendship was of great value to him. By society his eccentricities in dress and manners were toned down; and his disposition to gloom was neutralized by the presence of a vivacious and charming woman. In his whole career this is the only bright period. Thrale died in 1781, and three years later his widow married Gabriel Piozzi, an Italian musician. Piozzi was a man of talent and honor, but Johnson could brook no divided affection. He never again saw the friend who had so long ministered to his comfort. Immediately after the marriage, the Piozzis went to Italy, returning to England in 1787. They lived at Streatham till 1795, when they settled at Bachycraig, Flintshire, Wales, an estate Mrs. Piozzi inherited from her father. They afterwards built a villa, named Brynhella, on the Clwy. There Piozzi died in 1809. Mrs. Piozzi passed her last years mostly at Bath, Clifton, and Penzance. She died, May 2, 1821. Mrs. Piozzi's only valuable contributions to literature are *Anecdotes of the Late Samuel Johnson* (1786) and *Letters to and from the Late S. Johnson* (1788). Of her occasional verse, the best is *Three Warnings*, published in the *Miscellanies* of Mrs. Williams (1766), containing also Johnson's *Fountains*, a prose tale, of which the heroine is Mrs. Thrale. While at Florence in 1785 Mrs. Piozzi associated with the Della Crusceans and wrote for the *Florence Miscellany*, afterwards ridiculed by William Gifford (q.v.). Consult her *Autobiography*, *Letters*, and *Literary Remains*, ed. by Hayward (London and Boston, 1861); Mangin, *Piozziana* (London, 1833); Seeley, *Mrs. Thrale*, life and selections from writings (London and New York, 1891); *Glimpses of Italian Society in the Eighteenth Century, from the Journey of Mrs. Piozzi*, by the Countess Cesaresco (London, 1892); Boswell's *Life of Johnson* (ib., 1791); and the *Diary of Mme. d'Arbly* (ib., 1842-46).

PIP. The hero of Dickens's *Great Expectations*, who on the death of his unknown benefactor, the convict Magwitch, instead of gaining the wealth he had anticipated, is reduced to poverty.

PIP. A disease of poultry. See ROUP.

PIPA (Neo-Lat., from the native name of the Surinam toad). A South American frog (family Pipidae), the 'Surinam toad' (*Pipa Americana*), celebrated for its extraordinary method of carrying its eggs in the skin of the back. It is a peculiar, ugly-looking creature. The whole skin is covered with small tubercles, and is dark in color on the upper surfaces, but whitish on the under side of the body. Everywhere the skin bears papillæ, each with a little horny spike, and many with a poison gland at the base. The back of the female is furnished with numerous cells or pouches, in which the eggs are hatched and the young undergo all their transformations. It was not until the process was observed by Bartlett, who watched captive specimens in London (*Proceedings of the Zoölogical Society*, London, 1896, p. 595) that the method of placing the eggs in this curious nursery

was understood. Late in April, 1896, Bartlett noticed that the male pipa toads were becoming very lively, and were constantly heard uttering their metallic, ticking call-notes. On examining them, two of the males were observed clasped tightly around the lower parts of the bodies of females, the hind parts of the males extending beyond those of the females. On the following morning the keepers arrived in time to witness the mode in which the eggs were deposited. The oviduct of the female protruded from her body more than an inch in length, and the bladder-like protrusion, being retroverted, passed under the belly of the male on to her own back. The male appeared to press tightly upon this protruded bag, and to squeeze it from side to side, apparently pressing the eggs forward, one by one, on to the back of the female. By this movement the eggs were spread with nearly uniform smoothness over the whole surface of the back of the female, to which they became firmly adherent. When the operation was completed the males left their places on the females, and the enlarged and projected oviduct gradually disappeared. The eggs are produced in the early part of the rainy season, when these highly aquatic frogs have plenty of water about them, and at that time it is very difficult to capture them. In the dry season these frogs collect in swamps and ditches, and sometimes come close to or into houses. Consult Gadow, *Amphibia and Reptiles* (London, 1901).

PIP'CHIN, Mrs. A character in Dickens's *Dombey and Son*. She kept an establishment for young children at Brighton, where Paul was sent.

PIPE. An implement for smoking tobacco, opium, etc. See TOBACCO-PIPE.

PIPE (AS. *pipe*, from ML. *pipa*, pipe, from Lat. *pipire*, *pipiare*, to pipe, onomatopoeic in origin). An artificial closed channel, or conduit, for liquids, air, or gases, often under high pressures. Pipes are composed of a great variety of materials, according to the uses to which they are to be put and the cheapness of the various materials in a given locality.

LEAD PIPES are known to have been used at Babylon, Rome, and Pompeii, and, like all lead pipe until recent times, were made from sheets of lead bent to a pear-shaped section, with the horizontal joint welded or soldered. About the beginning of the sixteenth century the casting of lead pipes was begun in England, the process having been invented by Robert Brooke. In 1790 an English patent for drawing lead pipe was granted, and a machine was built for pressing lead pipe through dies. As the larger sizes of lead pipe have to be very thick to retain their shape and withstand high pressures, and on account of the high cost of lead pipe and for other reasons, such pipe is but little used now in diameters of over 2 inches or so, but it is made up to 4 inches, and, though rarely, to 6 or 8 inches. At the other extreme, it is made as small as $\frac{1}{8}$ inch, inside diameter. Modern lead pipe is pressed through dies in a continuous length. The molten lead is poured into a cylindrical hole in a hydraulic press. In the centre of the hole is a metal rod or core the same diameter as the pipe. When the metal begins to solidify the press rises and forces the

soft, hot lead through a die, the diameter of which corresponds with the interior diameter of the pipe. The total pressure used is about 400 tons, distributed over a 14- or 16-inch cylinder.

Block-tin pipes are made in the same way as lead, except that they are cold-pressed. Most of the block-tin pipe is used in soda fountains, or to convey beer, or in chemical works.

CAST-IRON PIPES. The general process of casting iron is described under **FOUNDING**. It may be said here that in some of the foundries the core is made by winding a spindle with a machine-made hay rope. Over the rope two or three layers of clay are packed, successively, after which the clay is shaped in a lathe, then dried in an oven. This core shapes the interior of the pipe. For the exterior a pattern is placed in a compartment known as a flask. Around the pattern tempered clay and sand are rammed to form a mold for the exterior of the pipe. The flask is then placed in an oven to dry the sand and clay, after which it is placed in a

MOLD FOR CASTING IRON PIPE.

vertical position, the core centred within it, and the space between the core and the mold filled with molten iron. After the core is drawn and the pipe removed the latter is coated to prevent corrosion. The standard length of cast-iron pipe is 12 feet, and its diameter ranges from about 2 to 60 inches, with occasional larger sizes. The great thickness of shell, which of course increases with the diameter, makes very large pipe too heavy for use where ready means for handling it are not available. This is partly obviated by casting in shorter lengths.

CLAY, EARTHENWARE, OR TERRA-COTTA PIPE. Near the close of the eighteenth century the manufacture of drain tile began to assume importance in England. Other forms of clay pipe followed soon after, and then came the vitrified clay or glazed stoneware pipe now commonly

known as sewer pipe. A machine for the manufacture of clay pipe was built at Ottweiler, Rhenish Prussia, about 1858.

DRAIN TILES are commonly mere cylinders of baked clay, designedly porous, and without provision for making joints. Sometimes, however, a short length of semi-cylindrical baked clay is

SOME OF THE MOST COMMON SPECIAL CASTINGS FOR USE WITH CAST-IRON PIPE.

laid over the abutting ends of the tiles. The standard vitrified clay or sewer pipe has sockets at one end for jointing, made of a little larger diameter than the pipe proper. Clay pipe is made by pressing or otherwise forcing the prepared clay (see **CLAY**) through a die, in the case of drain tile, and then cutting it into short lengths; or it is pressed in a mold, consisting of an outer shell, to form the exterior, and a core for the interior, besides which there is a special mold for the socket. After the socket is formed its mold is removed and the straight portion of the pipe pushed through.

To obtain a glaze, salt is placed in the fire holes of the kiln while the pipe is being baked. Upon being volatilized the salt combines with the silica in the clay. Drain tiles are quoted by manufacturers in diameters of 1½ to 12 inches, and are made in lengths of 12 to 15 inches. Vitrified pipes run from 2 to 36 inches in diameter, and are generally 2, 2½, or 3 feet long. There is a tendency to longer pipes, for the sake of reducing the number of joints. The lengths have to be restricted to 3 feet, to keep the pipes straight.

WOOD PIPES. Bored logs were used at Boston, in the first public water-supply system in the United States, in 1652, and at Bethlehem, Pa., in the pumping system of water-works built from 1754 to 1761. Most, if not all, these primitive wood pipes were simply logs with holes bored in their centres, and one end of each log tapered off to fit into the bore hole of the next log. Similar pipes are still used, but principally in the rural districts. Improvements have resulted in a style of pipe with a smooth circular interior and exterior, an asphalt-coated iron or steel band wound tightly around the pipe to give it strength, and a coating of asphalt over both the bands and wood for preserving the exterior from alternate drying and wetting. The joints are made by boring out one end of each

pipe to a larger diameter than the other, and turning down the other end to a like exterior diameter, then inserting the small end of one pipe in the large end of the next; or both ends of the pipe may be bored, as described, and the space thus formed may be filled by inserting a short length of pipe just thick enough so its inner side will be flush with the inside of the main pipe.

To avoid the limitations in size incident to bored logs, and to secure still greater facility in transportation and construction, particularly in rough country, pipes built up in place from wood staves are now used. In its present form wood stave pipe is composed of staves cut internally and on the edges (or radially) to form a conduit of the desired diameter. By breaking joints a continuous pipe is secured. The staves are held together and strength to resist any desired moderate pressure is secured by the use of steel bands or rods, provided with serew ends and nuts for tightening.

Since about 1895 smaller sizes of stave pipe, for which the construction just described is not suitable, have been made by winding them spirally with steel rods under tension by means of a machine; a little later small, wire-wound stave pipe was put on the market.

WOOD-FIBRE PIPES, in sizes from 1½ to 8 inches, in lengths of 5 feet, with screw coupling joints, are made and used for conveying gas, acids, and water, under a pressure of not more than 50 pounds. They are made from wood pulp. (See PAPER.) A thin sheet of pulp is wound around a core until the requisite thickness is obtained. The pipe thus formed is dried, impregnated with a wood preservative, and then has its ends turned in a lathe to form joints.

WROUGHT-IRON PIPES. The earliest wrought-iron pipes appear to have been made from an over-stock of gun barrels, early in the nineteenth century. The small end of one tube was serewed into the large end of the other. The pipes thus made were used to convey illuminating gas. The longitudinal joints were lap-welded. The increasing demand for wrought-iron gas pipe led to the adoption of butt-welded pipes of uniform size and thickness, united by sockets or couplings into which the ends of the pipe were serewed. Like the gun barrels, these pipes were welded by hand, a few inches at a time. In 1825 Cornelius Whitehouse invented a process of butt-welding which was, in its essentials, continued in use through the remainder of the century. He first rounded up the iron plate, or skelp, then heated half the length of the pipe and drew it through two dies by means of a chain. The dies pressed the heated metal together. This patent was bought by James and John Russell, pipe manufacturers, one of whom had just patented a process of butt-welding by pressing the edges together, but in which only a few inches could be welded at a time.

With the development of steam engineering larger and stronger pipes were demanded. The Russells bent their energies to meeting this demand by improving on the old lap-welding process already described. This appears to have been about 1835, but whatever the date, their process for lap-welding, like theirs for butt-welding, involved the main principles still followed. In the recent process of lap-welding pipe

and tubes the strips or plates of metal are heated, have their edges beveled or scarfed by passing through rolls, and then drawn through a die and formed with edges overlapping, ready to be welded. The partly made pipe, or skelp, is now heated a second time and welded by passing it through two rolls, the inner lap resting on a stationary mandrel, which corresponds to a blacksmith's anvil. Finally, the pipe thus made is straightened, threaded, serewed into a coupling, and tested by means of water pressure. Butt-welded pipes are now made by drawing a heated plate, by means of tongs, through a conical-shaped die, thus pressing the edges so firmly together that they unite. The further steps in the process are the same as for lap-welded pipe. Butt-welded wrought-iron pipe is made in small sizes, from ½ to about 1 inch in diameter, and is tested at an internal pressure of 300 pounds per square inch. Lap-welded pipe is made in sizes from 1¼ or 1½ to 30 inches in diameter, and is often subjected to very high pressures.

Pipes are also drawn from hollow or cylindrical ingots formed by passing a heated round billet through diagonal rolls and over a mandrel. By reheating and rolling under pressure the ingot is finally brought down to the desired diameter and thickness. It is then annealed, pickled, and cold-drawn, to give it the desired finish. In the Mannesman process, invented in Europe, and patented in America in 1887, pipe is rolled from a solid, but heated, bar or rod by means of two tapering rolls and a mandrel.

STEEL PIPES are made in the same general way as has been described for wrought iron. In addition, they are sometimes cast and are frequently riveted for large sizes, as described below.

In 1901 patents were granted for the *Bartlett-Kent process* of rolling large sizes of seamless steel pipe from hollow cast ingots or cylinders. The range of sizes proposed by the manufacturers is 12 to 30 inches in diameter, with shells from ½ to 1¼ inches thick. The essential parts of the machine are two sets of internal and two sets of external rolls, all placed at right angles to the axis of the pipe being rolled and all having curved surfaces corresponding to the inner and outer circumferences, respectively, of the ingot which is being rolled. There are three rolls in each set, making altogether contact with about one-half the respective surfaces of the ingot. The second set of rolls in each case is so placed as to come in contact with those portions of the ingot which are not touched by the first set. In addition, the ingots can be rotated through a part of their circumference. The machine is fully described in the *Iron Age* (New York) for April, 1901.

RIVETED WROUGHT IRON AND STEEL PIPES have their longitudinal and frequently their circular joints riveted, instead of welded. Wrought-iron sheets, rounded and riveted, have long been used for stovepipes, and in 1853 a California miner laid a 5 or 6 inch length of ordinary stovepipe for hydraulic mining. In a few years this sort of pipe, only heavier and better made, was in general use.

Both *spirally riveted* and *spirally welded steel pipe* have been used, and the former is still on the market. In each case plates of steel are

wound spirally to form a tube, spiral joints being heated and welded by a machine hammer in one case, and lapped and riveted in the other. The sections of pipe thus made are joined in the trench. Steel pipes with longitudinal locking bar joints have been used extensively in Australia, the chief instance, as well as one of the most remarkable pipe lines in the world, being the Coolgardie pipe line, which is 328 miles long and 30 inches in diameter. Water is pumped

pressure to both the plates and bars. The circular joints are made with sleeves. The contract for the line was let in 1898.

CEMENT PIPES AND CONCRETE PIPES are molded from the materials named. (See **CEMENT** and **CONCRETE**.) The cement pipe is made and shipped in sections. Concrete pipe is molded in place either by shifting along a movable mold and core, or by means of molds or forms consisting of an inner and an outer shell, between which the concrete is packed. During the last part of the nineteenth century steel rods and steel nettings were built into concrete pipe to give it greater strength.

PIPE JOINTS may be grouped as calked, screwed, flanged and bolted, and riveted. The calked joints are used almost wholly for vitrified clay pipe, other than drain tile, and are very largely used for cast-iron pipe. They are sometimes used for steel. Pipes with calked joints generally terminate in an enlarged, curved bell or socket at one end, and are either the same size and shape as the main pipe at the other end, or have a projecting ring. This smaller end is known as the spigot or bell. After one piece of pipe has been inserted in another, the space between the hub and the socket is packed with lead or with cement, the lead generally being used for cast-iron pipe. In place of a hub and socket, plain-ended pipe may be inserted in sleeves, or pipe of slightly larger diameter, and calked as described. Screwed joints are effected by threading the outer ends of the pipes and screwing them into or onto some form of coupling, also provided with screw threads. Flanged and bolted joints have a projecting ring at each end, with holes drilled through it, parallel to the axis of the pipe. Bolts are inserted in these holes. By using washers or packings of leather, rubber, or soft metal between the flanges, and by turning up the nuts on the bolts until they are tight, very tight joints can be made in this way. Riveted joints have been mentioned in the paragraph on riveted wrought iron and steel pipes. These joints, longitudinal as well as circumferential, may be made by lapping one edge over the other and riveting the two together; or the two metal edges may be butted against each other, a strap or band placed over the seam, and rivets inserted and headed each side of the seam. The requisite strength of joints is secured by decreasing the space between the rivets and by putting in two or three rows of the same.

BIBLIOGRAPHY. The literature of the subject is scattered through the engineering papers, proceedings of engineering societies, and books on the applied arts employing pipe. A paper by Jesse Garrett on "Making Cast-Iron Pipe" (*Journal of New England Water-Works Association*, Boston, September, 1896) contains some interesting historical matter relating to various kinds of pipes used to convey water, besides describing briefly the manufacture of cast-iron pipe. The journal named contains much other material on the manufacture and uses of the various kinds of pipes. See also: Crane, "Early History of Gas Pipes" (*Engineering Record*, New York, July 8, 1893), for the wrought-iron pipe; various committee reports on *Coating Cast Iron and Steel Pipes* (Proceedings of American Society of Municipal Improvements, Allegheny,

JOINTS FOR PIPE OF VARIOUS MATERIALS.

through it to supply gold fields in the interior, 1313 feet above the source of supply. The pipe is made by bending two plates to semicircular shape, and inserting their edges in steel bars with a groove on each side, then applying heavy

Pa., 1897 to 1900). For a few of the many uses of pipes, see HEATING AND VENTILATION; IRRIGATION; SEWERAGE; WATER SUPPLY; and WATER-WORKS.

PIPE-CLAY. A term applied to almost any fine clay (q.v.) comparatively free from iron and other impurities, having a grayish-white color, a greasy feel, and high plasticity. Some pipe-clays are used for the manufacture of tobacco-pipes and white pottery; others are employed for making sewer-pipe. Pipe-clays are common in the United States, and occur in many geological formations, notably the Cretaceous, Tertiary, and Carboniferous. See CLAY.

PIPEFISH. A name given principally to species of the family Syngnathidae, but also applied to various other species which, like the above, have a long, tubular snout. The body is long, slender, and covered with bony plates firmly connected, so as to form a sort of carapace. The tail is often long and slender, and sometimes is used as a prehensile organ. The fins are minute, the pectorals sometimes and the ventrals always wanting. Their food consists of small marine animals and the eggs of fishes; and they may be seen slowly moving about, with curious contortions, poking the long snout into

abundant along shore among the eel-grass, and when standing on their heads in the midst of it perfectly simulate one of the gently moving blades, and are thereby protected from observation. Like the sea-horse (q.v.), to which pipe-fishes are nearly related, the males have brood-pouches on the ventral side of the body, usually situated on the under side of the tail, but sometimes farther anterior, formed by two folds of the skin meeting and coalescing in the median line. The young are carried in this pouch until some time after they have escaped from the egg, going out and returning when alarmed, but at last are turned loose by the pouch bursting. There are about 15 genera and 150 species, small and sluggish, inhabiting the warmer seas, sometimes entering fresh waters. The common pipe-fish of the Atlantic coast is *Siphostoma fuscum*. Consult: Gunther, *Introduction to the study of Fishes* (London, 1880); Goode, *American Fishes* (New York, 1888).

PIPE LINES, OIL AND GAS. Wrought iron pipes jointed to form conduits of great length, used to transport petroleum oil or natural gas from the wells or fields to the point of utilization, or, in the case of oil, to the refinery or market. In the trunk lines the oil is pumped, often surmounting great elevations and requiring heavy pressures. Gas is often pumped, the frequency and intensity of pumping pressure increasing to a marked extent with the diminution of the pressure from the wells.

OIL PIPE LINES originated in the Pennsylvania fields. They were first suggested by Gen. S. D. Karns, in November, 1860. His idea was to lay a line from Burning Springs to Parkersburg, and let the oil gravitate to the Ohio River, where it could be loaded and shipped. The distance was about 36 miles. The line was never laid. In 1862 J. L. Hutchinson, of New York, laid a siphon over a hill from the Tarr Farm to a refinery at Plumer, Pa. In 1863 he laid a second line, three miles in length, through which he pumped oil from the Sherman well to a refinery. He placed 10-inch air chambers 50 to 100 feet apart. The joint leakage was so great that both these lines were abandoned.

The first successful line was laid in 1865 by Samuel von Syelle, of Titusville, Pa. Other lines followed and numerous companies were organized and consolidations effected. The new mode of transportation met with violent and riotous opposition from teamsters and others interested in hauling oil in wagons. In 1875 a 4-inch line, about 60 miles long, was laid from the lower oil country to Pittsburg. Up to this time most of the refineries had been located near the wells, but it being found more advantageous to locate the refineries on the seaboard and the Great Lakes, pipe lines were rapidly laid to the chief cities so situated in the northeastern part of the United States. The second pipe line of great length was laid from Bear Creek to Cleveland, Ohio. It was 111 miles long, 6 inches in diameter at the outset, and 5 inches in diameter after passing the final pumping station. By 1892 the National Transit Company, alone, had secured control of or built the following great trunk lines: Bear Creek to Pittsburg, 55 miles; Olean to Buffalo, 56 miles; Bear Creek to Cleveland, 111 miles; Colegrove to Philadelphia, 235 miles; Millway to Baltimore, 66 miles; Olean to New York, over 300 miles. Later, it added a

A PIPEFISH STANDING UPRIGHT IN EEL-GRASS.

every crevice in search of food, and sometimes assuming a vertical position with the head downward, poking into or stirring the sand. They

line from Lima, Ohio, to Chicago, eight inches in diameter and some 205 miles long, which has since been duplicated. Besides the National Transit Company there were a dozen or so other companies in 1892. In 1901 two companies controlled practically all the pipe line in the United States, but most of the mileage belonged to the National Transit Company. The extent of main, branch, and field pipes controlled by the National Transit Company (Standard Oil) has been placed by a representative of the company at as high as 35,000 miles.

At river crossings the pipe is either carried on bridges or laid on and anchored to the bed of the stream. At the Hudson River crossing a trunk line laid prior to 1893 is anchored to two sets of heavy chains, parallel to and some 25 feet from the pipe, held down by heavy weights. This line is inclosed in a second pipe. Across the salt marshes near New York the line is incased in concrete, to prevent corrosion.

The first oil pipe line was laid in Russia in 1879 to reach a refinery at the so-called Black Town of Baku. It was eight or nine miles long. In or about 1895 there were 22 pipe lines in Russia, some of which were eight inches in diameter. In July, 1900, a pipe line 143 miles long, from Mikhoilovo to Bohem, was put in use. It is for refined oil only, from the Baku deposits, supplementing the railway over a section where transportation is difficult.

PUMPS are required on the pipe lines, since these climb hills and mountains many hundred feet high. The pumps are of the high pressure, compound, condensing type, the later ones being high duty. (See PUMPS AND PUMPING MACHINERY.) The head under which the pumps work may vary, of course, with the topography of the country through which the line is passing, but it is largely dependent on the friction alone in long lines of small pipe.

NATURAL GAS PIPE LINES are often similar to the wrought iron lines described above, but they are also composed of riveted steel plates, and even of cast iron. Another variation from the oil pipe lines is the size of the gas mains, 16 to 24 inches or more in diameter, instead of 4 to 8 inches. It is said that the Chinese used bamboo pipes for natural gas and that a wooden main 20 miles long was laid from a well at West Brookfield, N. Y., to Rochester as early as 1865, or thereabouts. The general utilization of natural gas in the United States, and also the construction of gas pipe lines, followed the development of the petroleum oil industry. In 1872 gas was piped to Titusville, Pa., through a 2-inch and a 3¼-inch iron pipe line, 5½ miles long. In 1876 a 6-inch main, 17 miles long, was laid to Sharpsburg, Pa., from the Harvey well, in Butler County. The feeders to the pipe lines are 2 to 2½ inches in diameter. The main lines are 40 to 50 miles in length. The pressures in various fields originally ran from 300 to 1000 pounds per square inch, but of late they have fallen off, year by year, until in many cases they are only a small fraction of the initial. This has necessitated *pumping the gas*. The first pumps were installed by the People's Company, of Pittsburg, Pa., in 1890. Now nearly every company supplying gas to the larger cities is compelled to pump in winter. The pumping is generally effected by some standard form of air compressor, driven by compound or triple expansion steam

engines. The gas itself is generally used as fuel, but sometimes coal is used in order to husband the diminishing gas supply. About 1900 some large gas engines, one of 1000 horse-power, were installed to operate the gas compressors.

Where natural gas reaches a city under high pressure automatic pressure reducers are employed to reduce the gas to a uniform pressure of 10 to 50 pounds before it enters the city distributing mains. On each consumer's service pipe another reducing and regulating valve maintains a pressure of about one-half pound.

BIBLIOGRAPHY. Consult: Redwood (and others), *Petroleum* (London, 1896); Groves and Thorp, *Chemical Technology*, vol. ii., "Lighting" (New York, 1895); *The Mineral Industry*, vol. ii. (New York, 1893). For more detailed descriptions of particular oil fields and lines, see *Proceedings of the British Association for the Advancement of Science* (1885); and *Engineering News* (June 13, 1885). For gas pipe lines a slight amount of additional information may be obtained from *Cassier's Magazine* (February, 1898). See GAS, NATURAL; PIPE; PETROLEUM.

PIPER. A fish of the North Atlantic coast, one of the gurnards (*Trigla lyra*), which reaches three or four pounds in weight and is delicate food.

PIPERACEÆ (Neo-Lat. nom. pl., from Lat. *piper*, pepper), THE PEPPER FAMILY. A natural order of about 1000 species of dictyodendrous shrubs (a few almost trees) and herbs (some climbing), natives almost exclusively of the hottest parts of the globe, particularly of Asia and America. None of them are found in cold regions. Most of the species are called pepper, but some are also known by other names, particularly those of which the fruit is not used as a spice, but of which some part is otherwise employed as betel, cubebs, matiao, and ava. Pepper (q.v.) is the most important product of the order. The chief genera are Piper and Peperomia.

PIPERAZINE, known also as DIETHYLENE-DIAMINE, ETHYLENIMINE, PIPERAZIDINE, and DI-SPERMINE. A compound formed by the action of ammonia upon ethylene bromide or chloride. Its formula is $C_4H_{10}N_2$. It is also produced by the interaction of ethylene bromide and aniline upon the addition of a solution of potassium hydroxide, forming di-phenyl-piperazine. By treatment of this with sulphuric or nitric acid and distillation with alkalis piperazine is produced. It appears as white, odorless, tasteless, deliquescent crystals which are freely soluble in water. Its use in gout and the uric acid diathesis depends upon its property of uniting with uric acid to form a very soluble compound which is excreted in the urine instead of forming calculi in the kidney. Its use in connection with these seems to be prophylactic, as its claims to a solvent effect upon concretions already formed have been exaggerated.

PIPERIN (from Lat. *piper*, pepper), $C_{17}H_{19}NO_3$. A weak basic substance found in pepper. It may be obtained by heating powdered pepper with alcohol, in the form of colorless well-formed prisms, which are insoluble in cold water, but dissolve readily in alcohol and ether. On heating piperin with caustic potash solution, it breaks up into piperic acid, $C_{12}H_{10}O_4$, and a remarkable oily

base called *piperidin* ($C_5H_{11}N$). Piperin is used for making heliotropin and sometimes as a substitute for pepper.

PIPE ROLLS. A name applied to the great or annual rolls of the English Exchequer, written for the treasurer. They are so called because of their resemblance to a pipe, or on account of the favorite comparison of the public treasury to a reservoir, into which every branch of revenue flowed through these pipes. They were written by the treasurer's scribe, and controlled by the Chancellor's scribe. They contained a statement of the King's revenue, drawn up by the sheriff of one or more shires, and an account of the expenditures made by the sheriff in his office. The chief item of the revenue was the 'ferm' of the shire, which consisted of the King's income from the royal demesne, the yearly fines paid by the boroughs for their corporate privileges, and the fines decreed in the county courts. Other items were the Danegeld, a tax levied to resist the Northmen, the profits of the pleas of the Crown, the King's feudal income from reliefs, escheats, aids, and the proceeds of the tallage of the royal demesne.

The oldest extant pipe roll is that of 31 Henry I. (1131). These rolls extend from the second year of Henry II. (1156) till 1833, when the ancient system of the Exchequer was abolished, with but two breaks of a single year, and are among the most valuable of records, preserved in the Public Record Office. In 1883 the Pipe Roll Society was founded, with the intention of publishing all the pipe rolls. Its publications (17 vols., London, 1884-97) include the 5-24 Henry II., forming a combination with the publications of the Record Commission. The latter had in 1833 published the pipe roll of 31 Henry I. and the Chancellor's roll of 3 John; and in 1844 the pipe rolls 2, 3, 4 Henry II. and 1 Richard I. Consult Hall, *Introduction to the Study of the Pipe Rolls* (London, 1884).

PIPE VINE. See ARISTOLOCHIA.

PIPI, *pé'pé* (Brazilian name). The ripe pods of *Cesalpinia Paipae*, used in tanning, and not infrequently exported with *divi-divi* (q.v.), though being inferior to *divi-divi*, they are little exported separately. They are easily distinguished from the pods of *divi-divi* because they are straight instead of curved. The plants grow in the American tropics. See *CESALPINIA*.

PIPING CROW, or CROW-SHRIKE. One of the Australian shrikes of the genus *Gymnorhina*—large, black and white, insect-eating, showy birds, with loud, piping voices, alluded to in such local names as 'organ-bird' (*Gymnorhina hyperleuca*) of Tasmania, and 'flute-bird.' The latter (*Gymnorhina tibicen*) is very common throughout Australia and frequents the gardens and lawns, hunting for grasshoppers, of which it eats enormous quantities. Its intelligence, lively manners, and considerable vocal powers make it a favorite cage bird. Dealers call these birds 'Australian magpies.' Compare *ORGAN-BIRD*.

PIPIT, or PIPIT-LARK. See TITLARK.

PIPPA PASSES. A dramatic poem by Robert Browning (1841). Pippa, a girl from the silk-mills at Asolo, on a holiday passes several groups of people at a critical moment in the lives of all, and by snatches of her song, which they

overhear, changes the fate of each, and in one case her own.

PIPPI, *pip'pé*, GIULIO, commonly called GIULIO ROMANO (1492-1546). An Italian architect and painter, the chief follower of Raphael. He was born at Rome, and of his early life little is known, except that at an early date he entered the school of Raphael. Vasari says that Raphael loved him as a son, and we know that he left all his property to Giulio and Penni, another pupil. He was certainly the master's most important pupil, on whom he chiefly relied for the execution of his designs, and Giulio assisted in the *Stanza del Incendio*, the *Loggie* of the Vatican, and in the Villa Farnesina. (See RAFAEL.) He was also employed to paint easel pictures in Raphael's studio, especially such as were intended for foreign patrons, like the large Madonna in the Louvre and the so-called "Pearl" at Madrid. After Raphael's death he assisted in the *Sala di Costantino* in the Vatican, himself painting the chief composition, the battle picture; finished, together with Penni, the "Coronation of the Virgin," in the Vatican Gallery; and himself painted, in an admirable manner, the lower part of Raphael's "Transfiguration."

After Raphael's death Giulio was the acknowledged head of the school, and was as important in architecture as in painting. Unfortunately, his architectural works at Rome have been either spoiled by restoration or left incomplete; but we know that he designed and decorated for Cardinal Medici Villa Madama and Villa Lante, of which frescoes a few fragments are preserved in the Villa Borghese. The best of his easel pictures are, perhaps, the "Madonna with the Cat," in the Naples Museum; "Apollo and the Muses," Pitti Palace (Florence); and his masterpiece of this early period, "The Stoning of Saint Stephen," the altar piece of Santo Stefano, Genoa. Other examples, both religious and mythological, are in Rome, the Uffizi (Florence), the galleries of Vienna, Dresden, the National Gallery (London), and especially in the Louvre, which is rich in his works. Compared with Raphael, his independent works show an utter absence of religious feeling and a lack of grace. The forms are often coarse, though the drawing is good, and the color is marred by the use of deep black shadows and a dull brick red. His work, on the whole, shows a greater influence of Michelangelo than of Raphael.

In 1524 Giulio went to Mantua at the call of Duke Federigo Gonzaga, who placed him at the head of all his artistic undertakings, and raised him to the nobility. Here he developed a remarkable architectural activity, rebuilding whole quarters of the city. He built the ducal palace (1535-40), which was decorated after his designs, prominent among which were a series of frescoes of the Trojan War. Among his other architectural works were the great Church of San Benedetto, ten miles south of Mantua: the interior of the Cathedral of Mantua; his own tasteful house (1544) built around a simple court, and ornamented with a fine rustica facade; and the greatest of all his achievements, the Palazzo del Tè, just outside the city walls. Though enlarged from a stable for the Duke's stud, this palace is the best preserved example of a princely villa of the golden age of Italian art. It is a one-story rustica building, in the Doric style,

The entire interior is decorated with stucco and frescoes, after Giulio's designs, by his pupils. The great hall has realistic portraits of the Duke's favorite horses, which are epoch-making in animal painting. Most beautiful of all the decorations are those of the second hall, representing the "Story of Psyche." Two of the original drawings for this cycle, preserved in the Villa Albani, are, perhaps, his most charming work. Of the remaining rooms the most famous is that in which the "Fall of the Giants" through Jupiter's thunderbolts is represented in a very realistic manner. The scenes are not divided by frames or paneling, and the spectator stands in the midst of the catastrophe, which is so realistically represented as to create the impression that the walls are falling in with the giants.

The chief characteristics of Giulio's Mantuan work are profound antiquarian knowledge and a pronounced tendency toward realism. The action is exaggerated and mannered, and in such frescoes as the "Fall of the Giants," which greatly influenced contemporary painters, it is already Barocco. Of his later religious works the most remarkable are the designs for frescoes in Sant' Andrea, Mantua, and for Torbido's paintings in the Cathedral of Verona. Of his later easel paintings the "Adoration of the Kings," in the Louvre, and the "Madonna della Catina" (Dresden), in which the Christ child is naively represented as being bathed, were executed by his own hand. Pippi was also at the head of all the Duke's engineering undertakings, and in draining the marshes about Mantua he contracted a fever, from which he died at Mantua, November 1, 1546, just as he was about to return to Rome, after having been appointed architect-in-chief of St. Peter's. Consult D'Arco, *Istoria della vita et delle opere di Giulio Pippi* (Mantua, 1892).

PIPPIN. See PEPIN.

PIPPRA, pí'prá (Neo-Lat., from Gk. *πίπρα*, variant reading for *πίπρῶ*, *píprō*, woodpecker; otherwise explained as of possible South American origin). One of a group of non-oscine, passerine birds composing the family Pipridæ, many of which are also known as ant-birds and as manakins (q.v.). They are chiefly South American, but a few species extend north into Central America and Mexico. They are small birds, resemble titmice in their habits, and seek their food in low bushes and near the ground. The males are gorgeously colored, with glossy black, scarlet, yellow, and sky-blue; the females are dull greenish or some other inconspicuous color. They are thick-set birds, usually with short, square tails, and short, broad bills, the upper mandible hooked and notched at the tip. The true manakins (*Manacus*) have the chin feathers elongated like a beard. Pipras are most nearly related to the cotingas, rock cocks, and American flycatchers (qq.v.). See Plate of COTINGAS.

PIPSIS/SEWA. A small evergreen plant. See WINTERGREEN.

PIQUA, pik'wá. A city in Miami County, Ohio, 73 miles west-northwest of Columbus; on the Miami River and the Miami and Erie Canal, and at the junction of the Cincinnati, Hamilton and Dayton and the Pittsburg, Cincinnati, Chicago and St. Louis railroads (Map: Ohio, B 5). It has the Schmidlapp Free School Library. Piqua is an important industrial centre, noted

particularly for its manufactures of linseed oil. There are also large sheet steel mills, iron works, stove and range works, strawboard mills, a furniture factory, woolen mills, etc. Good water power for manufacturing is afforded by the river. Piqua is governed by a mayor, elected every two years, and a unicameral council. The water works are owned and operated by the municipality. Population in 1890, 9,090; in 1900, 12,172.

PIQUET, pé'ká' (Fr., piquet, peg). A game of cards, of great antiquity and considerable scientific possibilities. Its laws, as published in Hoyle's *Short Treatise on the Game of Piquet* in 1744, remained in force until the adoption of the rules of the Portland Club in 1873. It is played by two persons with a *cuchre* pack. Ace is highest and counts eleven, the other cards ranking as in whist. After cutting, the dealer gives the two top cards to his adversary, then two to himself, and so on until each has twelve cards. If the hand of either player contains no face card, it is called *carte blanche* (white card), and he scores 10 at once. The "elder hand" (the non-dealer) must discard one of his cards and take another from stock, but he may discard as many as five and take a like quantity. The younger hand must discard one also and may discard three. The players then announce the combinations of their cards, and each replies according to whether he has, or has not, an equal or greater number. "Good," "equal," or "not good," and scores "the point" according to the number of points the rules apportion to his combination. The play then proceeds, the leader of a counting card (ace, king, queen, knave, or ten) counting one for each card led, whether he wins the trick or not, and the winner of each trick leading for the next, as in most card games. The younger hand must, if possible, follow suit. If the leader wins the trick, the opponent counts nothing, but if he wins the trick he counts one. The winner of the last trick counts two. If one player wins more than half the tricks he adds ten to his count. If he wins all he adds forty. The variations of scoring and play for *carte blanche*, or a hand of only plain cards, *Point*, the strongest suit, *sequenc*, *quatorze*, *trio*, *pique* and *repique*, are too intricate to be described except by the laws of the game, for which consult Cady, *Piquet* (New York, 1896); "Cavendish," *The Laws of Piquet, with a Treatise on the Game* (London, 1882); "Aquarius," *Piquet and Cribbage* (London, 1883).

PIRACICABA, pé'rá-sê-ká'bá. A town of the State of São Paulo, Brazil, on the left bank of the Piracicaba River, 273 miles west of Rio de Janeiro, and on the São Paulo-Piracicaba Railway (Map: Brazil, H 8). The town carries on a brisk trade in coffee and sugar and utilizes the water power of the river for milling purposes. Its population in 1894 was about 5000.

PIRACY (ML. *piratia*, from Lat. *piratica*, piracy, fem. sg. of *piraticus*, from Gk. *πειρατικός*, *peiratikos*, relating to a pirate, from Gk. *πειρατής*, *peiratēs*, pirate, one who attacks or tries, from *πειράν*, *peiran*, to attempt, attack, from *πέρα*, *peira*, attempt, attack; connected with *πῶρος*, *poros*, passage, Skt. *par*, to cross, and ultimately with Eng. *fare*). Robbery on the high seas directed against the whole body of civilized States, rather than against any particular State. The

rules of international law provide that the penalty upon conviction may be death. But *piracy jure gentium*, or piracy as defined by international law, and piracy as described by the municipal law of a particular State, must be distinguished.

Three requirements are necessary to constitute an act of *piracy jure gentium*: First, it must be an act of adequate violence. It need not be necessarily an act of depredation. While the pirate is generally merely a robber, acts done by unauthorized persons for political ends have been deemed piratical, though the *animus furandi*, the intent, was wanting and there was no purpose of indiscriminate aggression upon the vessels of all nations. Thus a single act of violence is sufficient, as the successful revolt of a ship's crew against its officers. If they gain control of the ship, they are pirates; if their attempt fails and lawful authority is never superseded, the act is one of mutiny only, not piracy. Second, it must be an act done outside the territorial jurisdiction of a civilized State. Some authorities have held that an invasion from the sea upon the coast of a civilized State to ravage and destroy without national authorization is piracy. But being done within the territorial jurisdiction of the State, it is subject to the municipal law thereof and is outside the jurisdiction of the international code. Yet an act of similar character against an unappropriated island and the robbing of civilized persons there engaged in trade, or missionary work, would be piracy. Third, the perpetrators of the act must be without the authority of any recognized political community. Acts which when done under national authorization are lawful acts of war are, hence, piracy when not so authorized, and the possession of two or more incompatible commissions is deemed to have the same effect as the absence of any. So if in time of war a privateer procures letters from each belligerent and preys upon the commerce of both, she is a pirate; but if a cruiser having a lawful commission exceeds her authority in making captures, she is not a pirate, for the State authorizing her originally is held responsible for her acts. For purposes of authorization recognition of independence is not required; but recognition of belligerency is sufficient to validate a commission authorizing acts of violence for belligerent cruisers; but if such a community ceases to exist as a political unit, the commission is no longer valid.

Attempts have been made to bring acts done by vessels under commissions from a revolted community, which has not obtained recognition of belligerency, under the protection of this rule. Several instances have occurred where a disposition has been shown to treat as pirates persons guilty of accepting letters of marque and reprisal from one of two belligerents when the other was at peace with the nation of which the privateer was a subject, but such an attitude is at variance with the general usage of nations.

Piracy is punishable by any State which captures the perpetrators, that is, a State has jurisdiction to try and punish all pirates seized by its vessels. One of the attributes of an independent State is the power to regulate its own criminal code, and it may declare certain offenses to be *piracy* not so regarded by international law. Such are acts of piracy as defined by municipal statute. These laws can have binding force only in the jurisdiction creating them; and, while sim-

ilar regulations may be adopted by other States, in the absence of special agreement between them the officers of one may not arrest or punish subjects of the other for offenses committed beyond its jurisdiction, even though such acts are defined as offenses by the laws of the State to which the offender belongs. Thus, while the slave trade is declared to be piracy only by virtue of municipal law, efforts have been made to bring it under international jurisdiction by agreement between the powers. This has not been effectually done, although after much international difficulty and dispute as to the right of search, etc., an international convention was finally reached in 1890 as a result of the conference of the civilized States, called at the instance of the King of Belgium, which provided for a complicated system of measures of repression.

See such titles as HIGH SEA; MARE CLAUSTRUM; MUTINY; SLAVERY, etc. Consult the authorities referred to under INTERNATIONAL LAW; CRIMINAL LAW, etc.

PIRÆUS (Lat., from Gk. Πειραιεύς, *Peiraiicus*, Πειραιεύς, *Peiræus*). The port of Athens, situated on a rocky peninsula about 5 miles southwest of the city (Map: Greece, B 6). The nearest point in the shore line to Athens is the long sandy beach of Phalerum, bounded on the east by Cape Colias and on the west by a rocky peninsula, with two principal summits, one, Munyehia, at the northeast, close to the bay of Phalerum, the other, Acte, at the southern end of the cape. In this promontory are three harbors. The smallest is on the east side of Munyehia; the next in size is southwest of Munyehia and northeast of Acte; the third and largest is on the west side of the peninsula, north of Acte, and is a large basin with two smaller bays at each side, almost landlocked between Acte and a tongue of land projecting from Eëtiona, on the Attic coast. This harbor is supplied with modern docks and a portion of it is used by the Greek navy. Over one-half of the foreign commerce of Greece passes through Piræus, which is also a considerable manufacturing centre, producing mainly textiles, brandy, leather, paper, and macaroni. The population in 1896 was 42,169, making Piræus the second largest city of Greece. The earliest port of Athens was Phalerum, and the advantages of the Piræus were first observed by Themistocles (b.c. 493-492), who began to fortify it. It was not till after the Persian Wars that the peninsula was surrounded with lofty and strong walls, the mouths of the harbors narrowed by moles so that they could be easily closed by chains, and the whole connected with the city by the Long Walls. The city was laid out by the famous architect Hippodamus of Miletus, probably in the time of Pericles, in a regular system of broad straight streets crossing one another at right angles and broken by frequent open squares. Wharves, warehouses, and porticoes were built along the harborside and a merchants' exchange was provided for the display of samples. The great harbor was the scene of mercantile activity, the smaller harbors being reserved for the Athenian navy, and the remains of the ship-houses in which the triremes were hauled up can still be traced. With the decline and ruin of Athens during the Middle Ages the Piræus naturally was abandoned, and the present city has been built since Athens became the capital of

Greece. According to the accepted nomenclature, the smallest harbor, now Fanari, is the ancient Munychia; the next, now Pashalimani, is Zea; the great harbor was known as Cantharus. Recently, however, strong reasons have been advanced for identifying Phalerum with Fanari, Munychia with Pashalimani, and Zea and Cantharus with the bays on either side of the great harbor. Consult: Wachsmuth, *Die Stadt Athen im Altertum* (Leipzig, 1874, 1890); Milchhöfer, "Peiraieus," in *Baumeister's Denkmäler des klassischen Altertums* (Munich, 1889); Gardner, *Ancient Athens* (London and New York, 1902); and a Greek pamphlet by Angelopoulos, *περὶ πειραιῶς, καὶ τῶν λιμένων αὐτοῦ, On Peiraus and Its Harbors* (Athens, 1898).

PIRANESI, pē-rā-nā'zē. GIAMBATTISTA (1720-78). An eminent Italian engraver, born in Venice, October 4, 1720. He studied under his uncle, Matteo Lucchese, and with Vasi in Rome. He worked as architect in Venice for a short time, and then settled in Rome, where he produced an enormous number of plates. Toward the end of his life he was assisted by his sons, Francesco and Pietro, and his daughter, Laura. As architect he directed some restorations and decorations in Santa Maria del Popolo, and the priory of Malta at Rome. He was a member of the Academy of Saint Luke (1761) and an honorary member of the Society of Antiquaries in London. He died in Rome on November 9, 1798. His best plates are engravings of architectural ruins. They are characterized by Rembrandt-like contrasts of light and shade. He did not hesitate to restore, with his needle, the missing parts of the ruins he was engraving, and he added statues, tombs, vases, or any detail he thought necessary to bring out the pictorial and poetical interest of his work. He left about 2000 plates in 29 folio volumes. They are nearly always of large size, and are executed both with the burin and etched line. His masterpiece is the series known as *Le antichità romane*, 1800 plates (Rome, 1750; Paris, 1836 et seq.). Notable plates in this collection are: "Temple of Neptune at Paestum," "Arch of Constantine," "Arch of Septimius Severus," "Arch of Vespasian," "Temple of Apollo," "Baths of Diocletian," "Temple of Janus," "The Coliseum," "Villa of Maecenas," and the "Temple of the Sibyl at Tivoli."

PIRANO, pē-rā'nō. A seaport of the Crownland of Istria, Austria, on a peninsula in the Bay of Largone, 13 miles southwest of Trieste (Map: Austria, C 4). It contains an old castle, has a deep harbor and several dock-yards, and is the seat of considerable commerce. Wine, oil, glass, soap, and chemical products are manufactured. The salt works of Pirauo are among the most productive in Austria. Population, in 1890, 12,326; in 1900, 13,339, mostly Italians.

PIRATE, THE. A novel by Sir Walter Scott (1822). The scene is the Shetland Islands, visited by the pirate Cleveland, the son of the half insane Norna, though she mistakes Mertoun for her child until the secret is revealed at the close.

PIRATE BUG. A bug of the family Reduviidae, a large group comprising more than 2000 species, all of which are predatory in habits and feed upon other insects; also known as 'assassin bugs' and 'cannibal bugs.' With many species the

beak is so strong that it is capable of piercing the skin of human beings. (See CONE-NOSE.) A notable example is the 'wheel-bug' (*Arius cristatus*), called by the negroes in the South 'the Devil's riding horse.' The eggs, which look like miniature leather bottles standing on end and in hexagonal clusters, are attached to the bark of trees, and hibernates. The young bug emerges by pushing off the cap of the bottle. It has a blood-red abdomen, and in walking frequently elevates the hind end of the body, curling it forward. It feeds upon soft-bodied insects, such as plant-lice, but as it grows, attacks larger insects, and when full grown will destroy big caterpillars and even beetles. The full-grown bug is black in color and captures its prey by stealth. Its coloration is protective. In the more southern States it is an important factor in the destruction of numerous caterpillars which defoliate fruit and shade trees. Consult: Comstock, *Manual for the Study of Insects* (Ithaca, 1895); Howard, *The Insect Book* (New York, 1902).

PIRATE PERCH (so called from its voracity). A strange little fish of sluggish streams along the eastern coast of the United States and in the Mississippi Valley, which is related to the perches, but has been set apart in a suborder

THE PIRATE PERCH.

Xenarchi. The single species (*Aphredoderus sayanus*) represents the only genus and family of this group, which appears to be a relic of an ancient type. Its color is dark olive, profusely speckled with darker points, which often make blackish streaks along the rows of the scales; two blackish bars cross the base of the tail; and the length is about five inches.

PIRAYA, pē-rā'yá, or **PIRAI**, pē-rí'. A South American fish. See CARIBBE.

PIRENE, pi-rē'nē. A spring at Corinth, sacred to the Muses. Various accounts are given of its origin, but the usual tradition makes it to have been struck out of the Acrocorinthus by Pegasus, who was captured by Bellerophon while drinking its waters.

PIRITHOUS, pi-rith'ō-ūs. King of the Lapithæ, and son of Ixion, or Zeus. At his marriage with Hippodamia the centaur Eurytus, while intoxicated, carried off the bride. In the consequent fight between the Lapithæ and Centaurs, Pirithous was aided by his friend Theseus, King of Athens, and subsequently, with his help, attempted to carry off Persephone from the lower world. For this both were bound to a rock by Plato, but Theseus was released by Hercules, while Pirithous was left to his punishment.

PIRKHEIMER, pirk'hī-mēr, WILIBALD (1470-1530). A famous German humanist. He was

born at Eichstädt, educated at Padua and Pavia, and on his return to Nuremberg (1497) became counselor to the Emperor Maximilian and held this post for twenty-five years. In 1522 he became counselor to Charles V., but soon after gave himself up entirely to scholarly studies. At the beginning of the Reformation Pirkheimer sided with Reuchlin, but he could not go so far as Luther, although he defended him at first, so that he finally took much the same position as Erasmus, with whom, as well as with Reuchlin, Celtes, Hutten, and especially Dürer, he was on most intimate terms. His scholarly activity was wide and embraced studies in mathematics, astrology, theology, and politics. He wrote an historical work, *Bellum Suitense*, dealing with the war in Switzerland in 1499, in which he had commanded the forces of Nuremberg (edited, with an autobiography, by Rück, Munich, 1895), and various translations from Greek into Latin. Consult: Hagen, *Wilibald Pirkheimer in seinem Verhältniss zum Humanismus und zur Reformation* (Nuremberg, 1882); Roth, *Wilibald Pirkheimer* (Halle, 1887).

PIRMASENS, pĕr'mā-zĕns. A town in the Rhine Palatinate, Bavaria, situated about 30 miles southwest of Speyer (Map: Germany, B 4). It has a Protestant church with a fine monument to Landgrave Louis IX. of Hesse. Its chief industry is the manufacturing of footwear, which is carried on on a large scale. Pirmasens is noted as the scene of a victory of the Prussians over the French, under Moreau, in 1793. Population, in 1890, 21,041; in 1900, 30,194, chiefly Protestants.

PIRNA, pĭr'nā. A town in the Kingdom of Saxony, Germany, situated on the left bank of the Elbe, about 11 miles by rail southeast of Dresden (Map: Germany, E 3). It has a number of churches dating from the thirteenth century, an old castle with an insane asylum, a realschule, a seminary for teachers, a school of navigation, and a municipal museum. The manufactures include leather, essential oils, enameled ware, pottery, various kinds of glass, etc. Pirna is first mentioned as a possession of the Bishops of Meissen in the tenth century. It attained considerable prosperity in the Middle Ages, but subsequently declined on account of the ravages of war. During the Seven Years' War the Saxons entrenched themselves in Pirna and were forced to capitulate to a superior force of Prussians on October 17, 1756. Population, in 1890, 13,852; in 1900, 18,295, chiefly Protestants.

PIRO, pĕr'ō. The name of two Indian tribes, one of North America, the other of the Southern Continent. (1) **PIRO**, a Pueblo tribe of Tañao stock, formerly occupying several villages along the Rio Grande, about the present Socorro and Magdalena, N. M., but now extinct, excepting a nearly Mexicanized remnant at Seneeu, Mexico. (2) **PIRO**, **CHUNTAQUIRU**, or **SIMIRINCHE**, a southern tribe of Arawakan stock (q.v.) occupying the headwaters of the Apurimac and Ucayali rivers, Central Peru. They were in part converted by the Jesuits between 1683 and 1727. They get the name of *Chuntaquiru*, 'palm tooth,' from their custom of dyeing their teeth black with the root of the chunta palm. They are expert boatmen and fishermen, and collect sarsaparilla and make manati oil for the traders. They dress in black cotton cloth.

PIROGUE, or **PERIAGUA** (Fr. *pirogue*, from Sp. *piragua*, canoe, from the West Indian name). A form of boat used on the Western rivers of the United States and in the West Indies and Central and South America. It is usually a 'dug-out' and made from a single log. But larger varieties are made from 'dug-outs' by splitting them in two and inserting one or more planks in the bottom to give greater width. When fitted with sails these boats usually have two masts which may be easily unstepped and taken down.

PIRON, pĕr'ōn', ALEXIS (1689-1773). A French poet and dramatist, famed for wit and epigram. He was born in Dijon, July 9, 1689, studied law, and in 1719 he went to Paris as secretary to Belle-Isle, grandson of Fouquet. With Piron's monologue in three acts, called *Arlequin Deucalion*, the comic opera got new life. *La métromanie* (1738) has, also, some dramatic merit. Piron's *Works* are in seven volumes (1776). The epigrams, often reprinted, are of most significance. Piron died in Paris, January 21, 1773.

PIROT, pĕr'ōt'. A town of Serbia, situated near the Bulgarian frontier on the railroad from Belgrade to Sofia, and 48 miles northwest of the latter city (Map: Balkan Peninsula, D 3). It is a fortified place of considerable strategic importance, and is noted for the manufacture of carpets. Population, in 1900, 10,421.

PISA, pĕz'ā. The capital of the Province of Pisa, in Tuscany, Italy, situated on both banks of the Arno, five miles east of the Mediterranean, 11 miles northeast of Leghorn and 49 miles west of Florence (Map: Italy, E 4). The equable climate favors Pisa as a desirable winter resort for persons having pulmonary troubles. The neighboring mountains (the Monti Pisani, five miles to the east) and the high ancient fortifications (over six miles in circuit) protect the city from winds.

It is defended by a citadel on the southwest. Its streets are quite regular and are well paved. The centre of life in Pisa, which is a quiet town, is the Lungarno—stretch of fine wide quays bordering both banks of the river from one end of the municipality to the other. Here are fine hotels and restaurants. The Arno is spanned by five bridges.

The glory of Pisa is the far-famed Piazza del Duomo with its cathedral, baptistery, Leaning Tower, and Campo Santo, all situated in the extreme northwest corner of the city. The splendid cathedral, or basilica, dates from 1063 and was restored at the beginning of the seventeenth century. It is a remarkably perfect example of the Tuscan-Romanesque. It is of white marble, varied with black and red stripes. It is crowned by a semi-dome which contains mosaics on gold ground by Cimabue and others. The façade rivals any in Italy. It is characterized by columns, arches, and galleries. In the interior are 68 antique columns taken by the Pisans in their wars with their enemies. Among the interesting contents is a handsome bronze lamp suspended in the nave, the swaying of which is claimed to have suggested the explanation of the pendulum to Galileo. The circular marble baptistery, adorned with numerous columns, stands in front of the cathedral. It belongs to the middle of the twelfth century. Its dome rises to a height of nearly 200

feet, and possesses a remarkable echo. The baptistery contains a Madonna by Giovanni Pisano, and a pulpit—a celebrated masterpiece—by Nicola Pisano. The beautiful marble campanile, or Leaning Tower (q.v.), rises in the rear of the church. The view from the top, reached by nearly 300 steps, is superb, embracing the Carrara and Apuan Mountains, the city, and the blue sea.

Northwest of the cathedral is the quadrangular Campo Santo (cemetery). It was laid out in the beginning of the twelfth century. Its soil was brought in ships from Mount Calvary, that the dead here might lie in truly consecrated ground. A decorative Tuscan-Gothic structure, planned by Giovanni Pisano, incloses the cemetery. On the outside are numerous flat arches borne by pilasters. Inside, an arched and covered colonnade surrounds the burial plot. Here are found very interesting and suggestive frescoes by Tuscan artists of the close of the mediæval era. Of these paintings the most remarkable is the "Triumph of Death." There is also a notable "Last Judgment." The monuments, sarcophagi, urns, friezes, memorial tablets, etc., in the cemetery proper are of exceptional interest. The Basilica San Paolo a Ripa d'Arno, founded by Charlemagne, but belonging in its present form probably to the thirteenth century, possesses a rich façade of yellow, gray, and black marble. Santa Maria della Spina is a beautiful little church in the French Gothic, dating from the same period and built for seamen. It was restored in 1872.

Among the palaces the attractive brick Gothic Agostini of the fifteenth century deserves mention, as does also the Toscanelli, where Lord Byron sojourned in 1822. In the Loggia de' Banchi is the present corn exchange. Near by is the Palazzo del Comune, containing the valuable Pisan archives. The university, founded in 1338, is in a huge building dating from the latter part of the fifteenth century. (See PISA, UNIVERSITY OF.) The municipal museum (founded in 1893) contains works by Tuscan masters, but nothing of great interest. The Palazzo Conventuale dei Cavalieri is at present a high normal school. The Academy of Fine Arts was founded by Napoleon in 1812. The Cateriniana Library contains about 60,000 volumes. Pisa has statues of the Grand Duke Leopold I., Garibaldi, Mazzini, and Grand Duke Cosimo I., by Giovanni da Bologna, near which last once stood the historic Tower of Hunger of horrible memory, described by Dante in the *Inferno*. (See GHERARDESCA.) The house where Galileo was born is shown.

Pisa is wealthy and in a thriving condition. Cottons are largely manufactured. Oil and marble from the vicinity constitute important shipments. The city was formerly a port on the sea, but the silting up of the Arno caused Leghorn to grow in importance. There are fine market halls, an extensive hospital, and four theatres. The rich gardened plain around Pisa, lined with lonely poplars, is interesting despite its flatness. The population of the commune of Pisa in 1901 was 61,321, of whom only about half resided within the city.

The city was probably of Etruscan origin. It fell to Rome in B.C. 180. The Romans embellished it and made it important. About A.D. 1000 it became a formidable commercial and naval rival of Venice and Genoa. Strongly religious, it played in that era a prominent rôle in the defense and

diffusion of Christianity, the Republic taking a conspicuous part in the Crusades. Its warring citizens took Sardinia from the Saracens, and finally destroyed their naval power in the Mediterranean. Corsica and the Balearic Islands fell to them. The city was in the full flower of its greatness in the twelfth and thirteenth centuries. It held the coast from near Genoa to the vicinity of Rome. It had many contests with Lucca and Florence; it was aggressively Ghibelline. But the fall of the Hohenstaufens was at length a blow to the city, and it met decisive defeat by Genoa in a great sea-fight off Meloria, near Leghorn, in 1284. A few years later the Genoese destroyed its harbor. It began to decline, gradually losing all its possessions, and in 1406 it fell under the sway of Florence. It shook off the Florentine yoke in 1494, only to be resubjected in 1509. Henceforth its history was part of that of the Florentine State and of Tuscany. About 1600 Pisa had only about 15,000 inhabitants. In the height of its prosperity it had no less than 150,000.

In art history Pisa earned a worthy name until supplanted by Florence. Its cathedral marks the beginning of Italian art of the Middle Ages. The only branch of art, however, in which Pisa left an important influence was architecture (particularly ecclesiastical architecture), though it gave no little impetus to sculpture, being the native city of Nicola Pisano and his son Giovanni. Consult Schübring, *Pisa* (Leipzig, 1902).

PISA, COUNCIL OF. A council held in the year 1409; not reckoned among the ecumenical councils. It was assembled in the time of the great schism which followed the removal of the popes to Avignon (see SCHISM, WESTERN; PAPACY), for the purpose of restoring the peace of the Church. The cardinals of both parties, desiring to put an end to the anomalous condition which existed, united to call a general council. Both claimants to the Papacy, Gregory XII. and Benedict XIII. (antipope), were notified by their adherents and requested to appear at its sessions. Both, however, refused and called synods of their own. The cardinals persisted, and proceeded to deliberate upon the case. Twenty-two of them were present, besides some 80 bishops and representatives of over 100 more, with a vast body of abbots, doctors, and other eminent ecclesiastics. After a formal citation of the rival popes the council, on their non-appearance, proceeded to declare them contumacious, and to examine their respective claims as though they had appeared. The result, after a protracted inquiry, was a decree by which they were both declared schismatics, and deposed from the Papal dignity, and their followers released from obedience. In the seventeenth session the cardinals entered into conclave to the number of 24, and unanimously elected Peter Philargi, who took the name of Alexander V. The council proceeded after his election to pass a number of decrees, for the purpose of giving validity to the acts done on either side during the schism. A vain attempt was made to obtain the submission of the still recalcitrant rivals, and it was resolved that a new council should be held within three years. The authority of this council, like that of the Council of Constance, is alleged by some Gallican divines to establish the superiority of a general council over the Pope. But the contention is made in reply that both these councils, and

PISA
THE CAMPANILE (LEANING TOWER) AND CATHEDRAL

THE BAPTISTERY

also that of Basel, must be regarded as abnormal assemblies, called to meet the special emergency of a disputed succession and of a doubtful pope, and that these principles cannot by any means be applied to the ordinary circumstances of the Church, or form a precedent by which to estimate the normal relations between a pope whose title is certain and undisputed and a general council regularly assembled in the ordinary circumstances of the Church.

There were two other councils at Pisa, in 1133, when Peter of Bruys was condemned, and in 1511, when certain cardinals endeavored to have Pope Julius II. condemned for not calling a general council to reform the Church.

PISA, UNIVERSITY OF. One of the oldest European universities. There existed at Pisa teachers of law and medicine as early as the twelfth century, but the real beginning of the university dates from the emigration of a large number of students and teachers from Bologna in 1338 on account of the Interdict of Pope Benedict XII. At the instance of the Pisans, Pope Clement VI. authorized the establishment of a Studium Generale, which was dissolved in 1359 for lack of funds. In 1364 a new authorization was obtained from Pope Urban V. for its re-establishment. With the loss of Pisan independence in 1406 the university ceased to exist, but it was opened again by Lorenzo de' Medici and flourished for a while. It soon went out of existence again. Cosimo I. de' Medici reopened it in 1543 and generously supported it. In 1544 a botanical institute, the first of its kind, was established and the university soon achieved considerable fame. With the decay of Italian universities it suffered the general fate. It was revived in 1808 by Grand Duke Leopold II. of Tuscany, who endowed it munificently. In 1839 it received a well-equipped physical institute. After the revolution of 1848 it was reduced to a mere natural science and mathematics section, but was reopened with all faculties in 1850 and has since maintained a high standing among Italian universities. In 1902 it consisted of the faculties of law, medicine-surgery, philosophy, and mathematics-natural science, and the engineering, pharmacy, veterinary, and higher agricultural schools. The attendance was 1074, and the library contained 130,000 volumes, 28,000 pamphlets, and 300 manuscripts.

PISACA, pē-shā'chā. The vilest and most malignant demons in Hindu mythology. In the Vedas they are opposed especially to the pitris (q.v.), and are frequently termed *kravyādas*, or eaters of raw flesh. They infest houses and villages, and as Agni (q.v.) is besought to restore the flesh which the Pisacas have devoured from the sick man, they seem to have been ghoulish in nature, and associated with ghosts of the malignant dead. In modern India the Pisaca is pre-eminently the spirit of a liar, adulterer, criminal, or lunatic. Sometimes, however, if the proper incantations be performed, this class of demons can be forced to cure diseases. The legendary accounts of the origin of the Pisacas vary. According to the earlier view, they, together with the Asuras and Rakshakas, were created by Brahma from the stray water which was scattered from the drops out of which gods, men, and other good beings had been formed. Other sources, however, regard them as the offspring of the *Prajapatis* or of *Prajapati* (q.v.) himself.

PISAGUA, pē-sā'gwā. A town of the Province of Tarapacá, Chile, on the Pacific Coast, 46 miles north of Iquique, with which it is connected by rail. It is the second city of the province, situated in a desert country, with a fair harbor, well-constructed streets, and modern houses. The great industry of the town is the shipping of nitre, which is brought by rail from the interior. Its population is about 8000. On April 18, 1879, Pisagua was bombarded and completely destroyed by the Chilean fleet, but after the cessation of hostilities was quickly rebuilt. Near the town (November 19, 1879) occurred a battle in which 6000 Chileans defeated the combined forces of Peru and Bolivia, numbering 11,000.

PISAN, pē'zān', CHRISTINE DE. See CHRISTINE DE PISAN.

PISANDER (Lat., from Gk. Πεισανδρος, *Peisandros*). A Greek poet. He was born at Camerus, in the island of Rhodes, and appears to have lived about B.C. 650, although some critics state that he was earlier than Hesiod, and was a contemporary of Eumolpus. He is remembered chiefly for his *Ἡράκλεια*, a poem in two books on the exploits of Hercules. In this Hercules was for the first time represented as armed with a club, and covered with a lion's skin, instead of the usual armor of the heroic period. By many it is believed that Pisander was also the first to fix the hero's labors at twelve, corresponding to the signs of the zodiac. The work was so highly praised by the Alexandrian critics that they assigned Pisander a rank among epic poets after Homer, Hesiod, Panyasis, and Antimachus. Only a few lines have been preserved.

PISANELLO, pē'zā-nē'l'ō, properly VITTORE PISANO (1380-1452). An Italian painter and medalist, who introduced the Renaissance into Verona. He was born at San Vigilio, near the Lake of Garda, in 1380. Concerning his early years and his art apprenticeship little is known. Certain features in his works point to Altieheri da Zevio as his master. He is to-day better known as a medalist. As such he invented a new process of casting medals and finishing them with the tool, and portrayed a number of contemporaries. Unfortunately, few of his paintings survive. He painted many works at Verona between 1417 and 1422, and in 1421-22 completed a fresco in the Sala del Gran Consiglio, Venice, where he was employed together with Gentile da Fabriano. His work at Pavia, in Saint John Lateran, Rome, and at Mantua has disappeared, and his easel pictures are extremely rare. His style may be best studied in the fresco on the arch of the Pellegrini Chapel in Sant' Anastasia, Verona, which has been made accessible through the Arundel lithograph, and in the "Vision of Saint Eustace," in the National Gallery, London. While pleasing in color, his compositions are dominated by the naturalistic tendency of the painter, and justify, when compared with contemporary works, the reputation he enjoyed as a depicter of birds, animals, and landscape. Consult: Heiss, *Les médailleurs de la Renaissance*, vol. i. (Paris, 1881); Spaventi, *Vittore Pisanello* (Verona, 1893); *Venturini, Gentile Fabriano e il Pisanello* (Florence, 1896).

PISANIO, pē-sā'nē-ō. The servant of Posthumus in Shakespeare's *Cymbeline*. He is sent

to murder Imogen; but, allowing her to escape, he deceives Posthumus, by means of a bloody handkerchief, into believing that she is dead.

PISANO, pō-zā'nō, ANDREA. See ANDREA DI UGOLINO.

PISANO, GIOVANNI (c.1250-1320). One of the greatest sculptors of mediæval Italy. He was a son of Niccolò Pisano, and was probably born at Pisa, where he entered his father's workshop as apprentice. His earliest recorded work is his share in the superb pulpit at Siena (1266-67). (See PISANO, NICCOLÒ.) The crowded composition and dramatic quality of his pulpit was probably due largely to Giovanni, who differed in these qualities from his father. This tendency was still held in check in such early works as the reliefs and statuettes of the fountain at Perugia (1274-78) and the decorations of Santa Maria della Spina at Pisa. It was fully developed in the pulpit of Sant' Andrea at Pistoia (1300), where the "Crucifixion" and the "Massacre of the Innocents" are particularly dramatic and tense, not to say exaggerated. This tendency to realism was also shown in the heads of many of his statues, which are character studies rather than types. A good instance of this, as well as of his love of allegorical subjects, is the group in the Campo Santo, Pisa, of four figures symbolizing the virtues characteristic of Pisa, whose figure crowns the group. The explanation of Giovanni's style lies in the fact that he was the first Italian sculptor thoroughly influenced by the Gothic transalpine school and that this influence came to him from Germany rather than France. One of his works, at least, the tomb of Pope Benedict XI, at Perugia, shows another influence, that of the Roman school, with its mosaics, its Gothic canopy and angels, and calm reclining figure. One of his most ambitious works, a large pulpit for the Cathedral of Pisa, has been reconstructed from remaining fragments. Aside from a "Madonna and Child" in the Cathedral of Florence, some few pieces attributed to him at Siena, Cortona, and Arezzo (where the monuments of Saint Margaret and San Donato are certainly not by his hand), the majority of his works are in the Campo Santo at Pisa. He influenced the style of the Pisan school of sculpture far more than his father, Niccolò, and his influence extended to Siena and other Tuscan cities.

The *Life of Giovanni* by Vasari would make of him, as in the case of his father, Niccolò, a prominent architect as well as sculptor, and with greater reason; from his design for the Campo Santo at Pisa, the façades of the cathedrals at Siena and Prato, if these are correctly attributed to him, he appears to have been the leader in the so-called round arch Gothic. The arcades of the Campo Santo are one of the masterpieces of Italian art. Consult: Perkins, *Tuscan Sculptors* (London, 1864); id., *Historical Handbook of Italian Sculpture* (New York, 1883); Dobbert, in Dohme, *Kunst und Künstler Italiens*, i. (Leipzig, 1878); and Marcel Reymond, *Le sculpture toscane* (Florence, 1900).

PISANO, GIUNTA. An early Italian painter. See GIUNTA PISANO.

PISANO, LEONARDO. The name sometimes applied to the Italian mathematician Leonardo Fibonacci (q.v.).

PISANO, NICCOLÒ (c.1206-78). An Italian sculptor and architect, generally regarded as the

founder of the Italian school of sculpture. His birthplace is a matter of dispute, some maintaining that he was a native of Apulia, whence he brought an art formed upon classical models. It is more likely, however, that he was born in Pisa, or in one of the two Tuscan towns called Puglia. Niccolò's study of the antique, especially of Roman sarcophagi, led him to treat the nude, to aim at rich effects of drapery, and at artistic grouping of figures. His earliest known work is a lunette at the Cathedral of Lucca representing a "Deposition from the Cross," the "Nativity of Christ," and the "Adoration of the Magi" (c.1237). His masterpiece is the famous six-sided marble pulpit of the baptistery at Pisa, finished in 1260; the body of the pulpit decorated with five reliefs rest on Corinthian columns. Between the reliefs are charming statuettes and the columns rest on lions. A figure of the high priest seems copied from that of an Indian Bacchus and others from a Roman sarcophagus, still in the Pisan Campo Santo. Among the bas-reliefs of the pulpit, which represent scenes from the life of Christ, those of the "Nativity" and "Adoration" are the finest. Niccolò's style here appears at its best, in broad, majestic, well-balanced figures, treated in very high relief. In 1265 Niccolò was commissioned to execute a similar pulpit for the cathedral at Siena, to which city he probably transferred his studio, as he was assisted in its execution by his son, Giovanni Pisano (q.v.), and his other pupils, Arnolfo (q.v.), Lapo Goro, and Donato. This pulpit was completed in 1268, and while even richer in form and sculpture than that at Pisa, has less unity of style. Meanwhile (1265) Niccolò had furnished a colleague, Guglielmo Agnelli, with the designs for a monumental carved marble shrine for the Church of San Domenico at Bologna, completed in 1267, the "Arca di San Domenico;" none of the reliefs or statues, however, was executed by his hand. Shortly before his death he designed, in 1274, and partly decorated with sculptures the beautiful public fountain at Perugia (see FOUNTAIN), completed by his son Giovanni; the statuettes rather than the reliefs are supposed to be by the father's hand.

As a sculptor Niccolò first freed Italian art from the shackles of imperfect technique, created individual types, and had an ideal of beauty. He was rather the culmination of the Romanesque epoch than the creator of a new style. His son Giovanni Pisano (q.v.) was the real founder of the Italian Gothic school of sculpture, slender, dramatic, and allegorical, in contrast to the heavy, calm, and classic style of Niccolò. Niccolò's works as an architect are less certain. The buildings attributed to him by Vasari, in his *Life of the artist*, are nearly all of problematic authenticity. He is known to have built in Pisa, and probably San Nicola (especially the tower) and Santa Caterina are by him; possibly even Santa Trinità in Florence. Consult: Dobbert, *Ueber den Stil Niccolò Pisanos und dessen Ursprung* (Munich, 1873); id., "Die Pisani," in Dohme, *Kunst und Künstler Italiens* (Leipzig, 1878).

PISANO, VITTORE. See PISANELLO.

PISAREFF, pē'sá-ryĕf, DMITRIY IVANOVITCH (1840-68). A famous Russian critic. Born at Znamenka, he graduated from the Saint Peters-

burg Classical Gymnasium, and took up philology. A successful review (1859) in the *Daen*, a magazine for girls, caused him to turn to literature. In 1860 he placed a translation of Heine's *Atta Troll* in Blagosvyetloff's monthly *Russian World*, of which he became coeditor. *Scholastics of the Nineteenth Century* made him the idol of the youth, who asserted that "thenceforth contemporary metaphysics and mysticism were dead." In May, 1862, the monthly was suppressed. In bitter mood Pisareff rewrote a suppressed review of his for an underground publication. As a result he was shut up for nearly five years in the Schlüsselberg fortress. All his best efforts, critical estimates of contemporary and preceding Russian authors, as well as his popularization of natural sciences, which exercised a powerful influence on the generations of the sixties and seventies, were written here. Given liberty in 1867, he went to recuperate on the shores of the Baltic, and lost his life while bathing. Rumors were rife that the Government had a hand in the matter. Pisareff's fame rests on his championship of two principles—emancipation of personality and utilitarianism. He has been berated as a savage utilitarian, advising poets "to make shoes and bake fish pies." In reality he demanded that when a writer could not say with Börne, "I write with the blood of my heart and the sap of my nerves," he should turn to more utilitarian work. Scientific achievements during the fifties, Mill's ardent plea for utilitarianism, and the liberation of serfs in 1861, account for Pisareff's ideas as well as for his popularity. Dying at twenty-eight, he left ten volumes of critical works (2d ed., 6 vols., Saint Petersburg, 1894).

PISCAT'AQUA. A river about 80 miles in length, forming the southern part of the boundary between Maine and New Hampshire (Map: New Hampshire, L 9). It empties into the Atlantic, forming at its mouth the harbor of Portsmouth.

PISCES, pîs'sêz (Lat., fishes). One of the main divisions, or phyla, of cold-blooded vertebrates, including the fishes in the more restricted sense. It is well marked off from the lampreys, which are commonly called fishes, and is characterized by the presence of persistent gills and the possession of paired appendages in the form of fins. See FISH.

PISCHEL, pîsh'cl, RICHARD (1849—). A German Sanskrit scholar, born in Breslau, and educated there and in Berlin. He was professor of Sanskrit in Kiel from 1875 to 1885, and then at Halle, and in 1902 went to Berlin. Pischel's especial field is classical Sanskrit, and more particularly the drama. He urges its independence from the Greek drama, and is particularly fortunate in his conjectures of dates and authors for famous plays. But he wrote as well on the Vedic period, publishing with Geldner three volumes of *Vedische Studien* (1889-1901), and on Prakrit grammar, *Hemacandra's Grammatik der Prakritsprachen* (1877-80); a Prakrit dictionary, *Hemacandra's Deçināmamāla*, with Bühler (1880); and *Grammatik der Prakritsprachen* (1900). His further work includes: *Kālidāsa's Çakuntalā*, the Bengali recension (1877); *Rudra'ta's Çrngāratilaka*, a rhetorical work (1886); *Die Heimat des Puppenspiels* (1900); and *Materialien zur Kenntnis des Apabhramsa* (1902).

PISCICULTURE. See FISH-CULTURE.

PISCINA, pîs-sî'nā (Lat., fish-tank). A water-tank, especially the cold plunge or swimming basin of a Roman bath. In ecclesiastical and modern usage, a small basin supplied with running water, particularly such a basin in a decorative setting applied to or set in a wall, as in the chancel of a church for the washing of the chalice after mass, or in the sacristy for the use of the clergy. These were often highly ornate in the mediæval and early Renaissance periods, consisting of a wall-niche, either single or double, richly adorned, containing one or two faucets, and a sculptured basin projecting from the wall.

PISÉ, pè'zâ', or **PISAY** (Fr., pounded, brayed, crushed). A material and a process of building which depends upon the adhesive character of many natural earths. Any soil which is found to pack in the hand may be used. Where the soil is very fat, with much clay in it, this construction is capable of enduring many years. The material is of the nature of unburned brick so much used in Western Asia in antiquity, but it is made up in the mass instead of being shaped in blocks for building. See BRICK.

PISEK, pîs'èk. A small town of the Crown-land of Bohemia, Austria, situated on the Wotawa, an affluent of the Moldau, 55 miles southwest of Prague (Map: Austria, D 2). It is still partly surrounded with walls, has an old castle, a gymnasium, a realschule, and schools of agriculture and forestry. The manufactures are woolen and cotton fabrics, iron wire, and musical instruments. Population, in 1890, 10,900; in 1900, 13,574.

PISEMSKI, pè'syëm-ské, ALEXEI FEOFILAKTOVITCH (1820-81). A Russian novelist, born in the Government of Kostroma. He was educated in Kostroma and at the University of Moscow. Until his retirement in 1874 he was in the Government service. His literary activity dates from *Boyarshchina* (1847). A long line of works followed, among which *Tyufyak* (1850), *A Love Match*, and the drama of peasant life, *A Bitter Lot* (1853), *Pitershehik*, and *A Thousand Souls* (1858), may be mentioned as the best. In all of these Pisemski appears as an over-sober realist, picturing life in its lower aspects without compassion or censure, and at times verging on cynicism. His hopeless pessimism discovers the basest motives in what appears to be respectable and good, as when in *A Thousand Souls* he drew only the vices and shortcomings of the whole liberal movement without a single attractive feature for relief. With a heart embittered by his critics, he published in 1863 his last great effort, *Turbid Sea*. The works following it, such as *Men of the Forties* (1869), *Whirlpool* (1871), *Burgesses* (1877), *Freemasons* (1878), and many plays, showed a falling off in his powers and received little attention from the critics. Grief at the death of his two sons, both professors at the Moscow University, hastened his end. His works were published in 24 volumes (Saint Petersburg, 1895).

PISGAH, pîz'gâ (Heb. *Pîsgâh*, boundary, from *pâsag*, to divide). A mountain of the Abarim range, east of the Dead Sea. It is to be noticed that Pisgah never occurs by itself in the Old Testament, but always with the definite article

in connection with 'top' or 'slopes.' In Deut. xxxiv. 1, the 'top of the Pisgah,' from which Moses reviewed the promised land, is identified with Mount Nebo (q.v.), and in the days of Eusebius *Fasga* was still used for the region of Mount Nebo. The double name may, for all that, point to varying traditions in regard to the incident in the career of Moses.

PISIDES, pis'-dēz (Lat., from Gk. Πισιδῆς), GEORGIOS. A Byzantine poet of the seventh century A.D. He was a Pisidian by birth, as his name signifies, but attained fame as a deacon of the Church of Saint Sophia in Constantinople, and as a keeper of the records in the same church. His poems, all in excellent iambic trimeters, are a *Hexameron*, a didactic cosmology; some hymns and epigrams; and three historical poems dealing with the wars against Persia, the siege of Constantinople in 626, and the victory of Heraclius over Khosru, and furnishing important data for the reign of Heraclius. The complete works are to be found in Migne, *Patrologia Græca*, vol. xxi.

PISID'IA (Lat., from Gk. Πισιδία). An ancient division of Asia Minor, bounded on the north by Phrygia, on the east by Cilicia, on the south by Pamphylia, and on the west by Lycia. It belongs to the modern Turkish Vilayet of Konieh. It was drained by the Cestus, Eurymedon, and Melas, the chief rivers of Pamphylia. The principal towns were Selge, Termessus, and Sagalassus. Antioch, sometimes called the Pisidian, seems to have been really in Phrygia. The wines of Amblada were celebrated, and salt and olives were chief productions. The country is wild and mountainous, abounding in picturesque scenery, and the inhabitants were bold and lawless freebooters who defied subjugation. The cities, however, were gradually Hellenized, and in Roman times the country seems to have enjoyed great prosperity, as is indicated by the splendid ruins at several places. Consult Lanckoronski, *Städte Pamphyliens und Pisidiens* (Vienna, 1890).

PISISTRATUS (Lat., from Gk. Πεισιστρατος, *Peisistratos*) (?-c.527 B.C.). The famous tyrant of Athens, son of Hippocrates and intimate friend of the lawgiver Solon, with whom he was closely related on his mother's side. He received an excellent education, and the charm of his manners as well as the generosity of his spirit was so great that, according to Solon, had he not been ambitious he would have been the best of the Athenians. But his desire for sovereign power led him to adopt a policy of artifice to attain his ends, which has deprived him of the reputation that the kindly character of his government might otherwise have obtained for him. Pisistratus first became prominent in connection with the war between Megara and Athens, which culminated in the capture of the Megarian seaport Nisæa and the island Salamis by Athens about B.C. 570-565. In this struggle he may have held the office of polemarch, and his ambition then spurred him to take advantage of the popularity thus gained to seize the sovereign power. He came forward as leader of one of the three parties into which Attica was then divided. These were the Pe-diaci (Πεδιακοί), or the Party of the Plain, consisting of the well-to-do landed proprietors; the Parali (Πάραλοι), the Party of the Sea-

board, to which belonged the wealthy merchant classes; and the Diacrii (Διάκριοι), the Party of the Highlands, chiefly a laboring population, jealous of the rich and eager for political equality. Pisistratus joined the Party of the Highlands, and attached to himself all the poorer citizens and the discontented by his liberal beneficence. When the time came for a decisive step, he drove into the market-place, and there, exhibiting certain self-inflicted wounds, called upon the people to protect him against his and their enemies, alleging that he had been attacked on account of his patriotism. Thereupon his followers, according to Plutarch, were ready to take up arms for him, a general assembly of the citizens was summoned on motion of Aristion, one of his supporters, and it was voted to allow him a bodyguard of fifty clubmen. Tradition says that Solon charged him with hypocrisy, but in vain. Pisistratus gradually increased the number of his armed attendants, and about B.C. 560, when he felt himself strong enough, he seized the Acropolis and established himself as tyrant over Athens. The leaders of the aristocratic party immediately fled from the city. What action Solon took is not definitely known; he died within two years after the establishment of Pisistratus's irresponsible rule. This rule, however, was not harsh or vindictive. Pisistratus attempted to continue unchanged the constitution laid down by Solon himself, and conferred many benefits upon the poorer citizens. But the parties of the Plain and the Seashore united against him, and in five years succeeded in driving him out. This coalition in turn was soon broken up, and Megacles, one of the leaders, made overtures to Pisistratus and secured his return. A family quarrel between them, however, caused a second expulsion of the tyrant about 550. He retired to Eubœa, where he remained for ten years, watching for his opportunity and making preparations to secure his return. He gained a following in many of the Greek cities, exploited the gold mines of Mount Pangæus, near the Strymon, and collected a force of mercenary soldiers. At length he was strong enough in friendship with other Greek States to attack Athens. When he landed at Marathon his adherents flocked to his standard, and after defeating the constitutional party he reestablished himself for the third time as tyrant about 540. He continued to hold this position without interruption until his death in 527 (528?). Then his power passed into the hands of his sons Hippias and Hipparchus (q.v.).

Pisistratus's rule was mild and beneficent. He reduced taxes, established the poorer citizens on estates, supplying them with the needed resources, cared for the old and the disabled, and extended Athenian influence abroad. He recovered Sygeum, which commanded the entrance to the Hellespont, and acquired the Thracian Chersonese. His administration is also famous for his encouragement of literature and the arts. Under his direction a splendid temple to Athena was erected on the Acropolis, the Lyceum was built, also a temple to Dionysus in Limnæ, and he established a new sanctuary for this god at the foot of the Acropolis. He began the great temple of Olympian Zeus, which was not finished till the reign of the Emperor Hadrian. He also carried through many internal improvements,

the most significant being that of the water supply. He purified Delos, the great shrine of the Ionian race, by removing all bodies buried within the sacred precinct. He made the Athenian religious festivals, in particular the great Panathenaic festival, more magnificent than they had ever been before. He had a new edition of the Homeric poems prepared by poets and scholars resident at his court.

PISO. A Roman family of the plebeian gens Calpurnia. The agnomina of the family were Frugi and Cæsonius. Its more important members are named below: LUCIUS CALPURNIUS PISO FRUGI, in B.C. 149, as tribune of the plebs, brought up the first law against extortion (*Lex Calpurnia de Repetundis*); in 133 was consul, and fought in the Servile War in Sicily, and was censor in 120. He opposed the reforms of the Gracchi. He is best known as author of an annalistic history of Rome down to his own time, of which a few fragments are published in Peter's *Historicorum Romanorum Reliquiæ*, vol. i. (Leipzig, 1870).—LUCIUS CALPURNIUS PISO CÆSONIUS was the father-in-law of Julius Cæsar, and in 58 became consul as a tool of the triumvir. He supported Clodius against Cicero, banished the latter, and was twice vehemently attacked by him for vicious administration of the Province of Macedonia. Having become censor in 50, Piso attempted to mediate between Cæsar and the aristocratic party, but was unsuccessful, and failing to join Cæsar in the Civil War, now won Cicero's hearty approbation. After Cæsar's murder Piso seems to have sided with Antony.—His son, who bore the same name (B.C. 48-A.D. 32), was high in the favor of Augustus and Tiberius; held the consulship (B.C. 15), and as prefect of the city (A.D. 17) was highly praised by Velleius Paterculus.—GNEUS CALPURNIUS PISO was consul with Tiberius (B.C. 7), and became his tool to check and harass Germanicus in the East, receiving the command of Syria (A.D. 18). He and his wife, Plancina, were suspected of poisoning Germanicus; Piso was abandoned by Tiberius, on whose orders he had acted, and in A.D. 20 committed suicide.—GAIUS CALPURNIUS PISO, a brilliant and popular young man, was robbed (A.D. 37) of his newly married wife by Caligula and banished by that Emperor. Under Nero he joined a conspiracy to murder the tyrant; on its discovery he opened his veins and died. He may be the Piso addressed in the panegyric *De Laude Pisonis*.—The last Piso to attain fame was LUCIUS CALPURNIUS PISO LICINIANUS, an adopted member of the family, who was named by Galba as his successor to the Empire, and was killed when Otho came to the throne (A.D. 69).

PISSARO, pè'sà'rò', CAMILLE (c.1830—). A French landscape and figure painter and etcher, born in Normandy, and the pupil of Melbye and Corot. He was already well known as a painter of Normandy landscape when the 'Impressionist' movement began, about 1874. He joined the innovators and went with Monet to England, where he was influenced by Turner. For a time he was head of the off-shoot from the 'Impressionists,' called the 'Possibilistes,' but afterwards his style became more general again. Like Monet, he is a painter of sunshine, and by preference sunshine in Normandy, and, like Millet, he is the

painter of the peasant and the field. Afterwards, he also painted the boulevards and the Parisians, always bathed in light and fresh with vibrant color. His works in the Luxembourg include "Les toits rouges," "Potagers," "Chemin montant à travers champs," "La brouette," "La moisson," "Cheminus sous bois," and "Le lavoir."

PISSELEU, pès'lè', ANNE DE, Duchess d'Estampes (or Etampes). See ESTAMPES.

PISTACHE, pîs-tâsh'. A genus of trees. See PISTACIA.

PISTACIA (Lat., from Gk. *πιστάκη*, *pistakê*, pistachio-tree, from Pers. *pistâ*, pistachio-nut). A genus of trees of the natural order Anacardiaceæ, having dioecious flowers without petals and a dry drupe with a bony stone which splits into two valves when ripe, exposing the bright green oleaginous kernel, which is used to flavor culinary preparations, ices, etc. The pistacia or pistachio tree (*Pistacia vera*), a native of Persia and Syria, but now cultivated in Southern Europe and Northern Africa, and in many places naturalized, attains a height of about 20 feet, has pinnate leaves, flowers in racemes, ovate fruit about the size of an olive. In the south of Europe and in the East, pistachio-nuts, sometimes

PISTACHIO-NUTS (*Pistacia*).

called green almonds, are much esteemed, and are exported to some extent, although they very readily become rancid. Oil is expressed from them for culinary and other uses. In cultivation one male tree is allowed to five or six fertile ones. The mastic tree, or lentisk (*Pistacia lentiscus*), yields the gum resin called mastic (q.v.). It is a native of the countries around the Mediterranean. The turpentine tree (*Pistacia terebinthus*) yields the turpentine (q.v.) known in commerce as Cyprus turpentine, Chian turpentine, or Scio turpentine, which resembles honey in consistency, is greenish yellow, pleasant-smelling and mild-tasting, and in its properties resembles the turpentine of the pines, but lacks acidity. The tree is about 30 or 35 feet in height, has pinnate leaves, of about three pairs of leaflets and an odd one; flowers in compound racemes; and nearly globular fruit. The kernel of the fruit is oleaginous and pleasant. The batoum tree (*Pistacia atlantica*), a round-headed tree of about 40 feet in height, a native of the north of Africa, produces a fruit much used by the Arabs, and a gum resin of pleasant aromatic smell and agreeable taste. This is chewed to clean the teeth and sweeten the breath. The fragrant oil of the kernels of *Pistacia olcosa*, a

native of Cochin-China, is used by the people of that country to impart a perfume to ointments.

PISTIL (from Lat. *pestellum*, *pestillus*, pestle). The central organ of an ordinary flower, containing the ovules, and developing into the seed-case. See FLOWER.

PISTOIA, pè-stō'yà, or **PISTOJA**. A city in the Province of Florence, Italy, situated at the foot of the Apennines, 20 miles northwest of Florence by rail (Map: Italy, E 4). It is well built, and it is surrounded by lofty and well-preserved walls. The city played a prominent part in the early history of architecture and sculpture, and many of its churches bear marks of the influence of the Pisani. The cathedral, built in the twelfth and thirteenth centuries, contains a remarkable silver altar and a monument to Cardinal Portogruerra, considered as the first work in marble by Verrocchio. Sant' Andrea, one of the oldest churches of Pistoia, is noted for its pulpit, the work of Giovanni Pisano, and San Francesco al Prato is remarkable for its frescoes of biblical scenes. The ancient palaces of Pistoia are especially interesting. The Ospedale del Ceppo is beautifully decorated with terracotta reliefs (dating from the sixteenth century) and medallions representing biblical scenes. The Palazzo del Comune and the Palazzo Pretoria are both in the Italian-Gothic style of the fourteenth century. There are an imposing bishop's palace, a seminary, an academy of sciences, and two libraries. The principal manufactures are iron and steel wares, especially fire-arms, silks, linens, woollens, paper, and glass. Pistols are said to have been first made here, whence the name. Population (commune) in 1881, 51,552; in 1901, 62,606.

Pistoia is the Roman *Pistoria* where Catinus was defeated in B.C. 62. It was the scene of much factional strife between the Ghibellines and the Guelphs. In the fourteenth century it became subject to Florence.

PISTOL (OF. *pistole*, from It. *pistola*, pistol, dagger, from *Pistoia*, from Lat. *Pistoria*, a town in Italy, near Florence). This member of the small-arms group was developed soon after the invention of the wheel-lock, in the desire to supply horse soldiers with a firearm. The result was a weapon called the pistol, which was first manufactured at Pistoria, in Etruria, about 1540, by Camillo Vettori. At their first appearance they were distinguished by very short barrels, and heavy, clumsy butts, which, surmounted by enormous caps, were very nearly at right angles with the barrel. It was not long, however, before the butts were lengthened out almost in a line with the barrels. The great majority of the pistols used in the sixteenth and seventeenth centuries were fitted with wheel-locks, for which they were best adapted. *Daggs* was the name of a peculiar and heavy pistol in common use toward the middle of the seventeenth century. German manufactured pistols of the wheel-lock type had also been adopted by many of the important cavalry corps of continental Europe, foremost among whom were the *Ritters* of Prussia. (See CAVALRY.) It is to dueling, however, that the pistol is indebted for nearly all the improvements since made in its effectiveness; for while occasional slight alterations have been made in the general pattern, the exterior appearance and method of handling the dueling

pistol of the nineteenth century was practically identical with that of the eighteenth. For military and sporting purposes, the pistol has experienced many strange shapes and designs during its evolution into the modern revolver. The earliest type seems to have been an arquebus with four chambers, a specimen of which is in the Tower of London Armory, and which is said to have been the personal property of Henry VIII. It belongs to the early part of the sixteenth century and has a barrel 2 feet 9 inches long, and the chamber 7½ inches, the bore being about ½ inch. There is a separate flash pan for every chamber, which is covered with a gliding lid and moved in rotation underneath the serpentine. The barrel, which is secured to the spindle, is strengthened by a rod fastened to its top, and the other extremity fixed to the butt of the gun. The lock consisted of a serpentine, passing through the stock and secured by a pivot. The serpentine extended below and behind the pivot, and thus formed a trigger, which on being pressed allowed the serpentine to fall into the flash pan, the weight of the trigger acting as a balance, and restoring it to its original position. In every instance the chamber had to be moved round by hand. Devices for the combination of firearms with some other form of weapon have been frequent from the days of the first discovery of firearms up to the beginning of the twentieth century.

The combination most frequently used has been the pistol and battle-axe, examples of which in the fifteenth century are not uncommon. The Dresden Museum is especially rich in examples of these and similar weapons. Combinations of pistols and daggers were also frequently met with between the fifteenth and eighteenth centuries; since then and up to the present day, inventions are constantly being recorded which have the same principle for their base. In 1896 a patent for a combined dagger and pistol was issued from the English Patent Office, and about the same time a pistol-lance was being advocated in both Russia and Germany, as an essentially effective cavalry weapon. The invention of the revolver, which is discussed under its own head, caused the pistol to be used principally for dueling and target shooting, and excellent weapons were made for these purposes. The revolver with its six or seven shots served as an important, valuable military weapon on account of its effectiveness at close range, but at the beginning of the twentieth century the indications were that the automatic pistol would replace the revolver for war purposes. Many of the British officers in the Boer War of 1899-1902 were equipped with automatic pistols, while in countries like Germany, where the officers' equipment is supplied by the Government, a self-loading pistol is rapidly taking the place of the revolver. The four best known types are the *Mausers*, the *Burchardt-Lugers*, the *Colts*, and the *Mannlicher*. Probably the best European example is the Burchardt-Luger, operated by the utilization of the gas arising from its discharge, which is made to operate the mechanism, open the breech, extract and expel the cartridge, reloading and reclosing the breech for a new discharge. The firer merely replenishes the mechanism when necessary, and pulls the trigger. It is capable of firing 103 shots per minute, or 48 in 28 seconds. It is of 7.65 millimeters (0.301 inch) in calibre, and

PISTOLS AND REVOLVERS

1. BORCHARDT-LUGER AUTOMATIC PISTOL
2. COLT AUTOMATIC PISTOL

3. SMITH AND WESSON ARMY REVOLVER

5. WEBLEY, MARK IV, ARMY REVOLVER

has a length of barrel of 120 millimeters. At the moment of firing the gas, acting on the base of the cartridge case, forces back the barrel and breech casing, causing them to slide along the grooves of the frame. The detachable breech follows the movement, but both breech and barrel are firmly connected. The cartridge case, which is operated by the extractor, strikes against the ejector projecting out on the interior right wall of the breech casing and is expelled, thus making way for the top cartridge of the magazine, which is forced in front of the cylinder by an interior spring. A double spring compressed by the recoil forces the detachable breech sharply forward. The trigger is pressed, the firing pin released, and the cartridge exploded. When the magazine is exhausted, the lug of the magazine presses a separate spring projecting in the frame and catching in the notch of the cylinder. At the same time the breech, instead of moving forward, is held in an elevated position in the rear. The line of sight being concealed, the firer is made aware that his weapon is empty. The pistol is recharged with a fresh magazine, which is inserted in the butt, an operation which may be instantly performed, and as the weapon may be kept in use for a considerable time without cleaning, this constitutes one of its greatest values. The most important American invention is the *Colt automatic pistol*, invented by J. M. Browning. It consists of three principal parts: the *frame*, the *barrel*, and the *sliding cover*. In the first are contained the trigger, the hammer, mainspring, and magazine; the *barrel* is secured to the frame by two strong links; and the *sliding cover* works in grooves on the sides of the frame, and, in the firing position, is locked to the barrel by three ribs, the tops of the latter fitting into corresponding grooves in the slide. Its calibre is 0.38 inch. The magazine is a metal slide which is loaded into the stock of the pistol from below and held in like position by clips, so that, like the Burchardt-Luger pistol, it may be instantly loaded. To load the chamber and make ready to fire, the slide is held with the thumb and the forefinger of the right hand, the pistol being held in the left hand. The slide is drawn back smartly, a movement which cocks the hammer, while the return action forces the uppermost cartridge of the magazine forward into the chamber and closes the breech. It has a safety device known as the firing-pin lock, which is also a rear-sight and must be raised. This device being raised and one cartridge discharged, the force of the powder gases causes the slide and barrel to recoil together about two-tenths of an inch until the barrel is stopped, forced downward by the two links already mentioned, and unlocked from the sliding cover. The slide, still moving upward, cocks the hammer, ejects the empty shell sideways, and compresses the recoil spring. The moment it arises at its rearmost position the slide is forced forward by means of a recoil spring, and, encountering the second cartridge on its way, carries it forward into the chamber of the barrel, the latter part of its motion carrying the barrel forward and upward. After this the slide engages automatically with the barrel, and the weapon is ready for the next shot. See the article REVOLVER for descriptions of modern revolvers and pistols; and SMALL ARMS for automatic and other firearms.

PISTOL. A character in Shakespeare's *Henry IV.*, *Henry V.*, and *Merry Wives of Windsor*, a braggart and blusterer, the follower of Falstaff and husband of Dame Quickly.

PISUM. The generic name of the pea (q.v.).

PITAKA, pī'tā-kā (Pali, basket). Any one of the three divisions of the Buddhist Scriptures. The three pitakas, collectively termed *tipitaka* or *pīṭakattaya*, 'basket-triad,' are the *Vinaya-pīṭaka*, or Basket of Discipline, the *Suttapīṭaka*, or Basket of Discourses, and the *Abhidhamma-pīṭaka*, or Basket of Metaphysics. The *Vinaya-pīṭaka* is composed of five works, the *Bhikkhuvibhanga* (Monk's Division), *Bhikkhuni-Vibhanga* (Nun's Division), *Mahāvagga* (Great Chapter), *Culla-Vagga* (Little Chapter), and *Parivāra-Pāṭha* (Concluding Text). While much of this is dry and technical, it has many passages of interest. The *Sutta-Pīṭaka* is the most important of the three for the philosophy and folklore of Buddhism. It is composed of the following five books: *Digha-Nikāya* (Long Collection), *Majjhima-Nikāya* (Medium Collection), *Saṃyutta-Nikāya* (Connected Collection), *Anguttara-Nikāya* (Add-One Collection), and *Khuddaka-Nikāya* (Little Collection), which is subdivided into fifteen parts, *Khuddaka-Pāṭha* (Little Text), *Dhammapada* (Religious Sentences), *Udāna* (Out-Breathing), *Itivuttaka* (Thus Said), *Sutta-Nipāta* (Descent of Aphorisms), *Vimāna-Vatthu* (Palace-Stories), *Peta-Vatthu* (Ghost-Stories), *Thēra-Gāthā* (Stanzas of the elders), *Thēri-Gāthā* (Stanzas of the Female Elders), *Jātaka* (Birth-Stories), *Niddōsa* (Exposition), *Paṭisambhīdā-Magga* (Way of Analysis), *Apadāna* (Achievement), *Buddha-Vanisa* (Lineage of the Buddha), and *Cariya-Pīṭaka* (Basket of Conduct). The last pitaka is of all the least interesting. It is composed of seven books, *Dhamma-Saṅganī* (Enumeration of Duties), *Vibhanga* (Division), *Kathā-Vatthu* (Subject of Discourse), *Puggala-Paṇṇatti* (Manifestation of Persons), *Dhātu-Kathā* (Discussion of Elements), *Yamaka* (Two-fold), and *Paṭṭhāna* (Cause). Consult Warren, *Buddhism in Translations* (Cambridge, Mass., 1896).

PITAVAL, pē'tā'vāl', FRANÇOIS GAYOT DE (1673-1743). A French legal writer. He entered the army, but afterwards studied jurisprudence, and in 1713 became an advocate at Paris. He is chiefly known for the compilation of *Causes célèbres et intéressantes* (20 vols., 1734-43). From him a similar collection, begun by Hitzig and Häring at Leipzig in 1842, took the name *Der neue Pitaval* (2d ed., 36 vols., 1857-72; new series, 24 vols., 1866-91).

PITCAIRN, JOHN (c.1740-75). A British soldier born in Fifeshire, Scotland. He entered the marine service and became captain in January, 1765, and major in April, 1771. For seven years he was stationed in Boston, and won the respect of the citizens. He was sent by General Gage to destroy the military stores collected at Concord, April 19, 1775. The minutemen at Lexington, refusing to disperse at his order, were fired upon and seven were killed. Major Pitcairn maintained until his death that the soldiers fired after the colonists. In the battle of Bunker Hill, June 17th, he was first in the third and fourth charges, and was mortally wounded by a negro soldier. His widow was allowed a pension of

£200 by the British Government, and his son, DAVID, became a distinguished surgeon.

PITCAIRN ISLAND. One of the most easterly of the Polynesian islands, and the southernmost member of the Low Archipelago. It lies in the Pacific Ocean, in latitude $25^{\circ} 3'$ S. and longitude $130^{\circ} 18' W.$, is about 2 miles long and 1 mile broad, and consists of a mountain surrounded by coral reefs. Pitcairn was discovered by Carteret in 1767, but remained uninhabited till 1790, when it was settled by a company consisting of nine mutineers from H. M. S. *Bounty* (see Blich, William), and 18 natives from Tahiti—6 men and 12 women. During the ten years following their settlement the island was a scene of disorder and lawlessness. In the year 1808 the sole survivors of the original settlers were one Englishman by the name of John Adams (formerly Alexander Smith), 8 or 9 women, and several children, the rest having fallen victims to disease and violence. The elements of disorder having been removed, the island began to grow under the wise management of Adams. In 1808 Pitcairn was visited by an American sealing ship, and in 1815 by H.M.S. *Britain*, whose captain was very favorably impressed with the peace and good order prevailing on the island. In 1839 it was formally taken possession of for the British Crown, and in 1855, when the number of inhabitants had reached 200, which was more than the island could maintain, they petitioned the British Government to be removed to Norfolk Island (q.v.), which was done in the following year. Since then some of them have returned to Pitcairn, whose present population is about 125. Consult: Murray, *Pitcairn Island* (London, 1885); Barrow, *Mutiny of the Bounty* (London, 1831); Brodie, *Pitcairn's Island* (London, 1850).

PITCH (assimilated form of *pick*, AS. *pician*, Ger. *picken*, to pick; connected with Eng. *pipe*). That characteristic of a sound which is determined by the rapidity of the vibrations producing it. In music there are two kinds of pitch, *absolute pitch*, which is the position of a tone considered in reference to the whole range of musical tones, and *relative pitch*, which is its position as compared with some other single tone. In ascertaining the relative pitch of a tone, C is considered the standard or starting tone, and the pitch of the tone in question is found by progressing from C either by skips of perfect fifths (quints) or by skips of major thirds (tierces). Tones determined by the former method are called *quint tones*, those found by the latter *tierce tones*. Relative pitch is, however, practically never used except for scientific purposes, since the difference in pitch between every tierce tone and its corresponding quint must be carefully calculated. For ordinary purposes the musical scale is divided into a series of octaves, to represent the absolute pitch of the notes. The absolute pitch of any tone is dependent upon the number of vibrations taking place in a second. Each musical sound is produced by a series of vibrations recurring on the ear at precisely equal intervals; the greater the number of vibrations in a given time the more acute or higher is the pitch. In stringed instruments the pitch is dependent upon the length, thickness, and degree of tension of the strings; the shorter and thinner a string is the greater its tension and the higher the pitch of the note. In wind instruments, where the

notes are produced by the vibration of a column of air, the pitch is dependent upon the length of the column set in motion; the shorter the column of air the higher the pitch becomes. The lowest tone used in music (C¹) is given by the largest-pipes of modern organs and has sixteen and one-half vibrations per second; but this tone is so unmusical that it is used only in conjunction with its overtones. The practicable range of musical tones is from C² (32 vibrations per second) to C⁴ (4096 vibrations per second). The note C² is the basis of modern pitch, and the history of pitch is a chronicle of the variations in the number of vibrations per second which have been assigned to that note; for, strange to say, there is no absolute standard of pitch. We have no record of what pitch was used early in the history of modern music, but at the time of Guido d'Arezzo (q.v.) the treble C seems to have had somewhere around 500 vibrations per second. Our first exact idea of pitch is gained from the sizes of organ pipes which were in use in the sixteenth century, and from these we find that it differed considerably according to localities. Different pitches were also used for secular and sacred music. Early in the seventeenth century, however, a 'mean' pitch was introduced, and for about two centuries this was an approximately standard pitch, since C only varied during that time from 498 to 515 vibrations a second. This is the so-called *classic pitch*, for it was during this period that the great masters of music lived. But with the growth of the orchestra and the increased importance of wind instruments, the pitch was gradually raised in order to obtain more sonorous effects; and various efforts were made to counterbalance the difficulties involved by a varying scale of pitch. In 1834 a congress of physicists at Stuttgart adopted *Scheibler's pitch* (true C-528). In 1859 a French commission of musicians and scientists reported in favor of C-522. This is the widely used *French pitch*. In 1887 it was formally adopted by the Vienna Congress, and is now often called *International pitch*. *Philosophical pitch* (C-512) is used considerably in theoretical calculations. *Concert pitch* was a high pitch of about C-540, much used in concert and operatic work during the middle of the nineteenth century. See **ACOUSTICS; MUSIC**; and consult Ellis, *The History of Musical Pitch* (London, 1880).

PITCH. See **TAR.**

PITCH AND HITCH. An indoor game played by teams of five on each side, with disks of galvanized metal $2\frac{3}{8}$ inches, in diameter, which are pitched from a distance of 10 yards into a receiver, a round rubber cup placed on the floor, having an opening at the top 5 inches in diameter. If the disk goes into and remains in the receiver it counts 1 point to the pitcher; if it goes in and springs out again, it counts 10 points. If on the pitch it falls outside the receiver, it does not count at all. The disks outside the receiver have to be picked up by pressing over them an inverted rubber cap fixed at the end of a rod. If any disk in transit falls out of the rubber cup, it counts 1 against the player for each fall. Each player pitches 12 disks in each of the innings comprised in the game. There are senior and junior leagues of clubs playing the game, with headquarters in Brooklyn.

PITCHBLENDE. The common name for the mineral uraninite (q.v.).

PITCHER, THOMAS GAMBLE (1824-95). An American soldier, born at Rockport, Ind. He graduated at West Point in 1845, and was assigned to the infantry. During the Mexican War he won the brevet of first lieutenant. He was promoted to be captain in 1858, and during the Civil War participated in the defense of Harper's Ferry (June, 1862), and the Virginia campaign of the same year, until the battle of Cedar Mountain (August 9, 1862), where he was severely wounded. For his gallantry on this occasion he was brevetted major in the Regular Army. Three months later he was commissioned brigadier-general of volunteers, but saw no further active service. On March 13, 1865, he was brevetted lieutenant-colonel, colonel, and brigadier-general in the Regular Army, for gallant and meritorious services during the war, and on July 28, 1866, was commissioned colonel of the Forty-fourth Infantry. From 1866 to 1870 he was superintendent of the United States Military Academy, and from 1870 until 1877 was governor of the Soldiers' Home near Washington. The next year he retired from the service, and from 1880 until 1887 was superintendent of the New York Soldiers' and Sailors' Home.

PITCHER PLANT. A plant whose leaves are modified so as to form pitchers, as in *Sarracenia*. See CARNIVOROUS PLANTS; NEPENTHES.

PITCHSTONE. An igneous rock of glassy or lithoidal texture, rich in contained water. To this abundance of water in their composition pitchstones owe their lustre, from which they receive their name. The term pitchstone is not used to indicate any particular composition of rock, but rather to designate a texture which may occur with rocks of any chemical composition, though it is developed in larger masses in the case of magmas of siliceous composition. From obsidian pitchstone differs in containing much water, while obsidian (q.v.) is nearly or quite water-free. The most remarkable pitchstones occur upon the island of Arran, Hebrides, and near Meissen, Saxony.

PITCHURIM BEAN. The seed of a tropical tree. See GREENHEART.

PITESCI, pē-tēsht'y'. A town of Rumania, situated on the main railroad, 65 miles northwest of Bucharest (Map: Rumania, E 2). It has some trade. Population, in 1899, 15,570.

PITH (AS. *pīpa*, pith). The central cylinder of soft tissues (parenchyma) inclosed by the woody cylinder of dicotyledonous and gymnospermous plants. It frequently dies, decays, and leaves the stems hollow, as in the elder.

PITHECAN'THROPUS (Neo-Lat., from Gk. *πίθηκος*, *pithēkos*, ape, monkey + *ἄνθρωπος*, *anthrōpos*, man). An organic genus combining the structural characters of man and the higher apes or monkeys. The type and sole species is *Pithecanthropus erectus*, founded by Eugene Dubois in 1894 on a calvarium (skullcap), two upper molars, and a femur found in marine Pliocene deposits near Trinil, Java, in association with bones of about a dozen extinct mammalian species. The cranium has been discussed critically by more than a score of the world's leading anatomists, of whom about one-fourth

regard it as simian, about one-third as human, and the others (including Baker, Dubois, Gill, Haeckel, Manouvrier, Marsh, Nehring, Pettit, and Verneau) as an intermediate form. All agree that if human it is more ape-like in form and size, and that if simian or pithecoïd it more nearly approaches the human type, than any other known cranium. The capacity is estimated at about, or slightly above, 900 cubic centimeters, that of the largest known anthropoid apes being 500 to 600, that of the Neanderthal skull (as estimated by Huxley) 1236, and the average human cranium running from about 1300 to 1600, with an extreme range of about 1100 to 2200. The teeth combine human and simian characters, while the femur clearly indicates an habitual erect attitude. The genus is of special interest as representative of the 'missing link' much discussed by students of human development during the third quarter of the nineteenth century; indeed, its characters were pre-vised by Haeckel, who in 1886 applied the name *Pithecanthropus* to the still hypothetical form, and by McGee, who in 1892 pointed out that the assumption of the erect attitude was necessarily the first essential step in the development of the human genus from lower forms. Dubois's earlier publications, including *Pithecanthropus erectus, eine menschenähnliche Uebergangsform aus Java*, are not readily accessible; a later paper, read before the Berlin Anthropological Society and printed in the *Anatomischer Anzeiger*, vol. xii., was translated and widely reprinted, in the *Smithsonian Report* for 1898 and elsewhere.

PITHO (Gk. *Πεθώ*). The Greek goddess of persuasion, called by the Romans Suada or Suadela, and considered the daughter of Aphrodite, in whose train she appears with Eros and the Graces.

PITHOM. One of the store-cities which, according to Ex. i. 11, were built by the Israelites during the Egyptian bondage. Through the excavations conducted by Naville in 1883 for the Egypt Exploration Fund, it has been identified with the Egyptian city of Per-Tum, 'Abode of Tum' (Coptic Pethōm), whose site is occupied by the mound of Tell-el-Maskhntah, or 'Hill of the Statue,' so called from a sculpture found there representing Rameses II. standing between the gods Rê-Harmachis and Tum. It is situated in the Wādī Tūmflāt, about 12 miles from Ismailiah, near the railway station Rameses. Pithom seems to have been built by Rameses II. to serve as a base of supplies for his armies operating in Asia, and was strongly fortified. Naville found there the remains of a great quadrangular wall of brick inclosing a space of about 55,000 square yards, within which were the ruins of a temple and a number of chambers constructed for the storage of grain. In later times, especially under the Ptolemies, the city was a place of considerable importance, and it was still in existence at a late date under the Roman Empire. By the Greeks it was called Heroopolis. Consult Naville, *The Store-City of Pithom and the Route of the Exodus*, Memoir I. of the Egypt Exploration Fund (3d ed., London, 1888).

PITKIN, TIMOTHY (1766-1847). An American lawyer, politician, and historian. He was born in Farmington, Conn., graduated at Yale

in 1785, studied law, and was admitted to the bar. He was for five years Speaker of the Lower House of the State Legislature, and was a member of Congress from 1805 to 1819. He is remembered, however, chiefly as the author of *A Statistical View of the Commerce of the United States of America* (1816), and a *Political and Civil History of the United States from 1763 to the Close of Washington's Administration* (2 vols., 1828), both of which are written with great care, and though now largely superseded by other works, are still frequently consulted by students of American history.

PITMAN, BENN (1822—). An American stenographer and artist, born at Trowbridge, Wiltshire, England, the younger brother of Isaac Pitman (q.v.). He came to the United States in 1853, and settled in Cincinnati, Ohio, in the same year. He at first published his brother's shorthand text-books, giving him credit for the system; but in 1857, when Isaac and his co-laborers made certain changes in the system, he refused to adopt them. During the Civil War he did some official reporting for the Government, and afterwards devoted himself to professional reporting until 1873. Pitman's artistic instinct, which had manifested itself in many ways, found distinct expression in 1873, when he became connected with the Cincinnati School of Design as teacher of descriptive art in its various phases, and especially of wood carving. In this latter field he introduced what has since become known as the 'Pitman School of Wood Carving,' which provides for the treatment of naturalistic designs and admits of very beautiful effects in wood sculpture. Although he abandoned his formal connection with the Cincinnati School of Design in 1877, he continued to do more or less art work, and his influence as an artist came to be considerable, particularly throughout the middle West.

PITMAN, CHARLES (1796-1854). An American Methodist minister. He was born near Cookstown, N. J., and entered the Philadelphia Conference in 1818; he had important appointments and served as presiding elder in three districts successively; he was corresponding secretary of the Missionary Society of the Methodist Episcopal Church, 1841-50. He was known as one of the most eloquent preachers of his denomination. Consult Malmsbury, *The Life, Labors, and Sermons of Rev. Charles Pitman* (London, 1887).

PITMAN, SIR ISAAC (1813-97). The inventor of the Pitman system of phonography. He was born at Trowbridge, Wiltshire, England; was educated at the normal college of the British and Foreign School Society of London; in 1832 began to teach a school at Barton-on-Humber, Lincolnshire, and was afterwards master of several other schools. In 1837 he published *Stenographic Sound-hand*, an exposition of the phonographic method, to the improvement and diffusion of which he directed every effort. When the English Government offered a prize of £200 for the best method of collecting the pence for prepaid letters, Pitman submitted a proposal to collect the postage by means of stamps, which should be engraved in small squares of an inch space, and plates to be 20 inches by 12, making 240 squares, the price of which at one penny a stamp would be £1; he also pointed

out the advantage to the public of being able to transmit small sums by means of such stamps. In 1842 he established the weekly *Phonographic Journal*, afterwards named the *Phonetic Journal*, which he edited for more than fifty years. For many years Pitman was greatly interested in the subject of reform in English spelling, and issued a number of pamphlets advocating radical measures. He was knighted in 1894, in recognition of his services to stenography. Consult Reed, *Biography of Isaac Pitman* (New York and London, 1890). For a description of his system, see **SHORTHAND**.

PITO, See **CHICA**.

PITONI, pè-tò'nè, GIUSEPPE OTTAVIO (1657-1743). A composer of the Roman school, born at Rieti. He was a pupil of the famous Pompeo Natale at Rome, and afterwards studied counterpoint under Foggia. Throughout his life he was connected in various musical capacities with most of the important churches of Italy, and at the time of his death was church *maestro* of San Marco, Rome. Most of his compositions have remained in manuscript and have been carefully treasured by the churches to which they belong. During his lifetime only one book of motets (1697) was printed. One of his most famous compositions is a *Dixit* arranged for sixteen parts, or four choirs, which is sung annually during Holy Week in Saint Peter's, Rome. He died in Rome.

PITRA, pè'trà', JEAN BAPTISTE (1812-89). A French ecclesiastic and author, born near Autun. He taught rhetoric in the seminary at Autun before he became a Benedictine monk at Solesmes. He was made cardinal in 1863 and librarian at the Vatican six years afterwards. His writings include: *Vie de Saint Léger* (1846); *Spicilegium Solesmense* (1852-60); *Hymnographie de l'église grecque* (1867); *Juris Ecclesiastici Græcorum Historia et Monumenta* (1864-68); and *Triodon Katanaction* (1879).

PITRÉ, pè'trà', GIUSEPPE (1843—). An Italian folklore scholar, born at Palermo. He was educated at Palermo and made a special study of the antiquities, traditions, dialects, and national songs of his native land, and was one of the founders of the *Nuove Effemeridi Siciliane* (1868). Besides his contributions to French and Italian reviews, he published *Biblioteca delle tradizioni popolari siciliane* (19 vols., 1870-95); *Curiosità popolari tradizionali* (10 vols., 1885-91); and *Bibliografia delle tradizioni popolari d'Italia* (1894).

PITRI, pit'rè (Skt. *pitṛ*, father). A term in Hindu religion applied to three classes of divine beings. In the Rig-Veda the pitris are the souls of the righteous dead who dwell with Yama (q.v.), and to whom sacred balls of rice and flour together with water are duly offered. (See **SRADDHĀ**.) In the Atharva-Veda they are divided into higher and lower classes, the older manes being in general the more venerated and blessed. After the Vedic period the pitris lose their importance as distinct objects of cult, although sacrifices are still offered to them in India. In its second usage, the term is applied to the ten Prajapatis or progenitors of mankind. (See **PRĀJAPĀTI**.) In the later Hindu period, however, the pitris denoted a much larger class of semi-divine beings. Manu (q.v.) enumerates various classes of pitris, those who were the

ancestors of the gods, those who were the ancestors of the demons, and those from whom the four castes proceeded. The Puranas divided the manes generally into seven classes, three of which are without form, or composed of intellectual, not elementary substance, and assume what forms they please, while the four other classes are corporeal.

PIT RIVER INDIANS. A group of small tribes, at present supposed to constitute a distinct linguistic stock, which Hale in 1846 designated as the Palaihnihan, occupying the volcanic mountainous region along Pit River, a head stream of the Sacramento, in northeastern California. From their custom, not known among other California tribes, of digging deep pitfalls for trapping deer, the river is said to obtain its name. The pitfalls, which were dug along deer trails and at watering places on the river, caused so many losses of cattle to the early settlers that the Indians were finally compelled to abandon the practice. The northern tribes of the group were of very low type, mentally and physically, due largely to the thinning out of the best specimens by the constant raids of the slave-hunting Modoc, but those lower down the stream were much superior, and were extremely warlike and hostile until crushed by General Crook. The position of woman was very low. When twins were born one was usually destroyed. Notwithstanding all this, they had strong affections and were extremely kind to the helpless. Cremation was the most common funeral method. They number now about 1100, of whom a few families are on Round Valley reservation, California, whither they were deported after one of the early wars; 80 persons, former captives and slaves of the Modoc, are on Klamath reservation, Oregon; and the main body, about 1000 in number, are still roaming about Pit River, having never come under agency control.

PITSCOTTIE, ROBERT LINDSAY OF (c.1500-65). A Scottish chronicler, born at Pitscottie, Ceres Parish, Fife. Connected with the noble family of Lindsays, he was a landowner in his native place, and chiefly is remembered for his *Chronicles of Scotland*, which cover a little-known period—the reigns of James II. and III. Their value rests not in accuracy, but in picturesqueness of style and dialect, and in the description of people and events, which are interesting, if not accurate. Sir Walter Scott in *Marmion*, and Mrs. Oliphant in *Royal Edinburgh* (1891), are indebted to Pitscottie's *History*, which was first printed in 1728, and a better edition of which was prepared by G. Dalrymple in two volumes in 1814.

PI-TSI. A tuber-bearing plant. See SCIRPUS.

PITT, WILLIAM, first Earl of Chatham (1708-78). A famous English statesman, often referred to as the elder Pitt. He was born in Westminster on November 15, 1708, and was educated at Eton and Trinity College, Oxford, but he never took a degree, for he was afflicted with gout from an early age, and was advised to travel, which he did for a short time. Nevertheless the disease never left him, and throughout life it remained a very serious hindrance. In 1731 he became a cornet in the army, and in 1735 entered Parliament for Old Sarum, the typical example of the 'rotten' boroughs. Soon after entering Parliament he was dismissed from

the army for supporting Frederick, Prince of Wales, in his course of opposition to King George II., and his biting satire made him also very obnoxious to the powerful minister, Robert Walpole. Almost from the very beginning Pitt was a power among the Commons on account of his oratorical abilities, and he contributed much to bringing about the downfall of Walpole in 1742. Thereafter he opposed the foreign policy of Carteret, especially the practice of paying subsidies to the Continental powers. His policy became very popular among the people; the Duchess of Marlborough left him in 1744 a legacy of £10,000, and in 1765 Sir William Pynsent, an eccentric gentleman, struck also with admiration for Pitt's patriotism, left him his whole estate. Late in 1744 some of Pitt's associates obtained seats in the Cabinet of Pelham, but the King had not yet forgiven Pitt. In 1746 the Government resigned, but shortly resumed power, and Pitt was appointed joint Vice-Treasurer of Ireland, and in the same year he was given the lucrative office of paymaster-general of the forces, and became a member of the Privy Council. At this time he received great praise for declining the special emoluments which usually went with the position of paymaster-general. In 1755, when Henry Fox (afterwards Lord Holland) was made Secretary of State, Pitt vigorously opposed the foreign policy of the Newcastle Cabinet, and as a consequence he was dismissed from office. Meanwhile the Seven Years' War (q.v.) had begun, and though Frederick the Great (q.v.) was gaining victories on the Continent, the English campaigns in America and elsewhere were unsuccessful. Hence in 1756 the King had to call upon Pitt, who had become the popular idol, to carry on the Government. A new Cabinet was formed of which the Duke of Devonshire was the nominal Prime Minister, but all real power was vested in Pitt. The latter immediately began vigorous measures to carry on the war, but the King did not give him loyal support and finally dismissed him on April 6, 1757. He had, however, to recall him almost immediately in response to the demands of the nation, and Pitt was given full control of foreign and military affairs.

Pitt's war policy was characterized by unusual vigor and sagacity. French armies were defeated everywhere—in India, in Africa, in Canada, on the Rhine—and French fleets disappeared from the seas. Pitt was practically absolute ruler of Britain, and the populace bestowed on him the title of the 'Great Commoner.' A change came, however, with the accession of George III. in 1760. Pitt was forced to take Lord Bute into the Cabinet, and was finally compelled to resign on October 5, 1761. As some recompense for his important services, Pitt received a pension of £3000 a year, and his wife, sister of George Grenville (q.v.), was given the title of Baroness Chatham. Until 1766 Pitt remained out of office, occasionally employing his eloquence to defeat obnoxious measures of the Government, and he opposed vigorously the various acts to tax the American colonists. On July 30, 1776, Pitt succeeded in forming a new Ministry to succeed the Rockingham Cabinet, and, as his health was very poor, he took the sinecure office of Privy Seal, and was created Viscount Pitt and Earl of Chatham. His acceptance of the peerage was very unpopular, and he also lost considerable influence, because

his impassioned eloquence was unable to move such a small body of men as were accustomed to attend the House of Lords. Ill health prevented Chatham from taking an active part in the Ministry, of which he was nominally the head, and he resigned on October 14, 1768, never to hold office again.

Chatham, however, did not cease to take an interest in public affairs. He spoke strongly against the arbitrary and harsh policy of the Government of Lord North toward the American colonies, and did his utmost to procure an amicable settlement of the differences, declaring that "England had no right under heaven to tax the colonists." But when America entered into a treaty with France, and it was proposed to remove the Ministers and make peace on any terms, Chatham, though in a dying state, appeared in the House of Lords, and in a powerful address protested against the disruption of the Empire and the implied prostration of Great Britain before France. It was the orator's last effort; exhausted by speaking, on rising again to reply to a query addressed to him, he suddenly fell back into the arms of his friends. He died a few days later, May 11, 1778. He was honored with a public funeral in Westminster Abbey, where a statue was erected to his memory at the public expense. In addition, the Government gave £20,000 to pay his debts, and conferred a pension of £4000 a year on his descendants.

Pitt's appearance was dignified and imposing, and added greatly to the attractiveness of his oratory, which was of the most powerful kind. His uprightness and irreproachable character compelled the admiration of his enemies; but his affectation and haughtiness frequently disgusted his friends. He had an intense love of country, his ambition being to make his native land safe against all contingencies.

Macaulay's "Chatham" is a very interesting essay. Consult also: Thackeray, *History of the Earl of Chatham* (2 vols., London, 1827); Cobbett, *Parliamentary History* (London, 1806-20); Horace Walpole, *Letters* (9 vols., London, 1880); id., *Memoirs of the Reign of George II.* (3 vols., London, 1848-51); Green, *William Pitt, Earl of Chatham* (London, 1901); Lecky, *History of England in the Eighteenth Century* (6 vols., 3d ed., London, 1883-90).

PITT, WILLIAM (1759-1806). A celebrated English statesman, often referred to as the younger Pitt to distinguish him from his father, William Pitt, first Earl of Chatham. He was born May 28, 1759, on his father's estate at Hayes. His mother was a sister of the well-known statesman George Grenville (q.v.). Pitt, on account of his delicate health, was educated at first at home, but when fourteen years of age he was matriculated at Pembroke Hall, Cambridge. He graduated in 1776, receiving an M.A., and then studied law, and in 1780 was admitted to the bar. In the same year he was elected to Parliament, taking his seat on January 23, 1781. He immediately joined the party that had followed his father, and hence was in opposition to the Government of Lord North. His maiden speech made a very favorable impression; and when in 1782 Rockingham formed a new Administration, Pitt was offered a well-paying subordinate position, but, though poor, he declined it. He had decided that he would accept nothing except a Cabinet office.

On May 7, 1782, Pitt made his first motion for a reform in the representation to Parliament. The motion was lost by a narrow margin, the vote being 161 against 141. The reformers did not make so good a showing again until 1831. Three months after his accession to office, Rockingham died, and Lord Shelburne became Prime Minister, while Pitt, though only twenty-three years of age, became Chancellor of the Exchequer. The Cabinet was met by a formidable coalition led by Charles James Fox (q.v.) and Lord North, and in 1783 Shelburne resigned. George III. offered Pitt the Premiership, but he declined, as he was not certain of the consistent support of the dominant factors in Parliament. The result was a coalition Ministry under the Duke of Portland, in which Fox and North were the leaders. Pitt on May 7, 1783, again brought forward the question of Parliamentary reform, but, though his plan this time was a definite and well-ordered one, the motion was lost by 293 to 149.

After Parliament had been prorogued Pitt visited the Continent, and was well received. On December 19, 1783, the coalition Ministry was dismissed after the defeat of a bill in the House of Lords, which aimed to transfer the Government of India to Parliament. Thereupon Pitt assumed the Premiership in the face of a powerful opposition in the House of Commons. His position was a desperate one. The House of Commons resented the interference of the King, whose action was of doubtful constitutionality. Between December 17, 1783, and March 8, 1784, Pitt was defeated in 16 divisions. The only recourse was either to resign or to order a new election; but Pitt postponed the election as long as possible. When at last he saw that the current of popular opinion had set in his favor, he dissolved Parliament, and the election proved to be a triumph for his Administration, he himself being returned for the University of Cambridge, for which he sat for the rest of his life.

Pitt was twenty-five years old at this time and the most powerful subject that England had had for generations. He ruled absolutely over the Cabinet, and was at once the favorite of the sovereign, of Parliament, and of the nation; and henceforth his life is identical to a great extent with the history of England. When Parliament met, Pitt's first work was the ordering of the finances, for there had been enormous deficits for many years. In this he was very successful. In 1784 he established a new constitution for the East India Company, the Board of Control being instituted. In 1785 he introduced his third reform bill, providing for the purchase of seventy-two 'rotten boroughs,' but the bill failed to pass, and the outbreak of the French Revolution soon after put an end for many years to serious attempts at Parliamentary reform. Pitt was the first British statesman to attempt to put into practice the principles enunciated in 1776 by Adam Smith. His bill, however, providing for free trade between England and Ireland failed in 1785. In the following year Pitt was successful in negotiating a liberal commercial treaty with France. In 1792 he supported Wilberforce's proposal for the abolition of the slave trade, but he could not carry the House of Commons with him. In the war between France on the one side and Austria and Prussia on the other he maintained strict neutrality so long as he was able, but the Paris massacres

of September, 1792, and the execution of Louis XVI. in January, 1793, so outraged the feelings of the English people that peace could no longer be maintained. In February the French Convention declared war against England. While the English were successful on the sea, Pitt opposed the French on land principally by means of heavy subsidies to his Continental allies, thus inaugurating the system which was followed throughout the Napoleonic wars. In his persistent enmity toward Napoleon he was opposed throughout by his great rival, Fox. While the financial difficulties caused by the outbreak of the war with France were at their height Irish affairs also became very perplexing. Pitt desired to relieve the Catholics of the disabilities under which they were laboring, but George III. compelled him to withdraw all such schemes. In 1800-01 a Parliamentary union with Ireland was effected, but it by no means allayed discontent. In order to relieve some of the financial difficulties of the nation, Pitt created a 'sinking fund,' which at considerable cost maintained the credit of the Government. Meanwhile Napoleon had defeated Austria in Italy, while Russia became neutral, so that England was left to struggle with France alone. In 1801 Pitt resigned because the King refused to accept his Catholic emancipation measures. He loyally supported the new Ministry of Addington in its attempt to make a permanent peace, which resulted in the Treaty of Amiens in 1802. When Pitt was no longer able conscientiously to aid Addington he withdrew from active participation in affairs. His health was poor and his finances were in disorder. On May 16, 1803, war was declared by England against France, and Pitt at once reappeared to aid his country. He criticised the weakness of the Government, and on May 10, 1804, again became Prime Minister. Pitt's vigorous measures resulted in the third great coalition against France, but, though the victory of Trafalgar cheered him the defeat of Austria and her ally, Russia, at Austerlitz on December 2, 1805, proved his death-blow. Shortly before he died he uttered the prophetic words, so well known: "Roll up the map of Europe; it will not be wanted these ten years." He died January 23, 1806, and was buried on February 22d in Westminster Abbey. His work did much to bring about the ultimate downfall of Napoleon, and in many respects Pitt may be considered England's greatest Prime Minister.

BIBLIOGRAPHY. Pitt's *Speeches in the House of Commons* have been published in three volumes (London, 1817); while an account of his parliamentary career is to be found in the *Parliamentary History*, 36 vols. (ib., 1803-10); and in Hansard, *Parliamentary Debates*. Consult also: Macaulay, "William Pitt" (one of the essays); Stanhope, *Life of William Pitt*, (2d ed., London, 1862); which is the best work on this subject; Rosebery, *William Pitt* in "Twelve English Statesmen Series" (ib., 1891); Sergeant, *William Pitt* (ib., 1882); Lecky, *History of England in the Eighteenth Century*, vols. iv. viii. (ib., 1882-90); May, *Constitutional History of England* (ib., 1863-65); Mahan, *Influence of Sea Power Upon the French Revolution, 1793-1812* (ib., 1893).

PITT, WILLIAM (1773-1857). See AMHERST, EARL OF.

PITTA (from Telegu *pitta*, a small bird). One of a group of passerine birds, known as *brèves* by the French. The characteristics are brilliant plumage, a very short tail, long legs, with scutellated tarsi, and, generally, a strong bill. They were long supposed to be allied to the thrushes, and several were called 'ground-thrushes' and 'ant-thrushes' in the books; but they are now understood to be more nearly related to the American flycatchers. Nearly 50 species have been described, inhabiting the Malay archipelago, China, India, and Australia, while one species occurs in western Africa. Their habits are terrestrial chiefly, and they live amid rocks and brush, hunting mollusks and insects among the fallen leaves, or digging for worms and ants. They are shy, quick, and not as often seen as their plaintive, whistling notes are heard. All are small birds of gaudy plumage, which shows such colors as scarlet, blue, and green. They make their nests on the ground and lay spotted eggs. Consult: Newton, *Dictionary of Birds* (London, 1893); Evans, *Birds* (New York, 1901); and authorities on Indian, Malayan and Australian ornithology. See Plate of COTINGAS, etc.

PIT'TACUS (Lat., from Gk. *πιττακός*, *Pittakos*) (c.B.C. 652-569). One of the Seven Wise Men of Greece. He was born at Mitylene in the island of Lesbos, and was a son of Hyrrhadus, a Thracian, and a Mitylenean mother of good family. He is celebrated as a soldier, statesman, philosopher, and poet. About B.C. 612, in conjunction with the brothers of the poet Alcaeus, he overthrew and killed Melanchrus, the despot of Mitylene. A few years later, about 606, he was engaged, at the head of the Mitylenean forces, in fighting the Athenians for the possession of the coast of the Troad near Sigeum. Though neither side was decisively victorious, Pittacus slew with his own hand the Athenian commander Phryno. For his services he would take but a small piece of land, which he dedicated to sacred uses; at a later time it was known as the *Pittacean Land*. On the banishment of Alcaeus, who was the leader of the aristocratic party, Pittacus, as being the most prominent democrat in the city, was in 589 chosen *asymnetes* (*ἀσυμνήτης*) or ruler with absolute power for ten years. As dictator he reestablished security and peace in the state, and enacted various laws. He is said to have died about 569. Of his poetry a few lines only have been preserved by Diogenes Laertius.

PITT DIAMOND. A famous stone, originally weighing 410 carats, now reduced to 136¾ carats, and considered the most brilliant and perfect diamond in existence, being valued at nearly \$2,500,000. It was found in the Parteaal mines of India, and was sold by a sailor to Thomas Pitt, Governor of Fort Saint George and grandfather of the first Earl of Chatham. It was sold in 1717 to the Duke of Orleans and hence received the name of Regent Diamond. During the French Revolution it was pledged in the hands of a Berlin merchant, and was afterward set in the hilt of Napoleon's sword. It is still among the regalia of France. See Plate of DIAMONDS.

PIT'THEUS. The father of Æthar, mother of Theseus. He was king of Troezen and a teacher of oratory.

PITTI PALACE. A celebrated Florentine palace of the Early Renaissance, now used as a royal residence. It is the largest palace except the Vatican in Italy, and one of the most imposing in the world. A typical Florentine palace of the fifteenth century, part fortress, part residence, it became a model for such structures. The imposing character of the façade is due to the use of rough-hewn stone, giving a massive effect, and to the simple and harmonious proportions of the three stories. This effect is heightened by its situation upon a hill on the left bank of the Arno; behind it are the beautiful Boboli Gardens.

The palace was designed in 1440 by Brunelleschi for Luca Pitti, then chief magistrate of the Republic. Brunelleschi lived to complete the first story and after Luca's fall the building was not resumed until the palace was purchased by the ducal family and made their residence. In 1568 Ammanati was employed to make a new design to replace Brunelleschi's lost plan. To him is due the celebrated court of the palace—a rather unfortunate attempt to use rustic work with pilasters. The wings of the façade date from 1620, being an addition to Brunelleschi's more simple plan, and the building was not completed till 1830.

Within the palace, and open to the general public, is one of the most important collections of paintings in the world, although numbering but 500 specimens. It is especially rich in Florentine masters of the fifteenth century, and possesses fine examples of Andrea del Sarto, Giorgione, Titian, Tintoretto, besides six of the very best Raphaels. Other European schools are represented by Dürer, Rembrandt, Rubens, Van Dyck, Murillo, and Velazquez.

PITTSBURG. The metropolis of western Pennsylvania, the second city of the State, and the county seat of Allegheny County. It is situated at the junction of the Allegheny and Monongahela rivers where they unite to form the Ohio, in latitude 40° 32' north and longitude 80° 2' 38" west (Map: Pennsylvania, B 3). It is 275 miles west of New York, 350 miles northeast of Cincinnati, and 450 miles east of Chicago. These distances are in a straight line. The mean average temperature is 53° F., the mean for January being 31° and for July, 75°. The altitude at the river level is 703 feet.

Although eleventh in population, according to the census returns, Pittsburg ranks fifth in commercial and industrial importance among the cities of the United States. This is due to the fact that surrounding the city proper are two other cities—Allegheny and McKeesport—and about fifty boroughs, at least thirty of the latter, as well as both cities, being closely allied with Pittsburg, and, for all business purposes, portions of it. An act of Legislature, approved in April, 1903, provides a method whereby these municipalities may be combined with Pittsburg. The ultimate aim of the bill is to make the city co-extensive with the county, which now has a population of over 800,000. The city proper contains 38 wards and has an area of 28.39 square miles. The original city occupied restricted limits between the Allegheny and Monongahela, but absorption of territory lying to the east greatly enlarged its bounds. A number of boroughs on the south side of the Monongahela River were

annexed in 1872, and are now connected with the old city by four free bridges. Several other boroughs have been since absorbed. Allegheny, which lies across the Allegheny River from Pittsburg, is connected with it by numerous toll bridges.

Pittsburg is the centre of the iron, steel, and glass industries of the United States. It is also the largest shipping point for bituminous coal, upon which its wealth is founded. The Pittsburg coal district, embracing an area of 14,000 square miles, is the richest coal field in the world. It is from the excessive consumption of coal in its mills and furnaces that Pittsburg derives its sobriquet, "The Smoky City." As a manufacturing city Pittsburg is best known, and until recent years it possessed all of the unattractive characteristics of such a community. Recently, however, great progress has been made, and fine streets, splendid boulevards, a system of parks, costly residences, and other evidences of municipal and civic pride have come into existence. In the older portion of the city the streets are narrow, ill arranged, and much congested, owing to the restrictive limits placed upon the district by the rivers. The chief retail streets are Fifth Avenue, Sixth, Wood, and Smithfield streets. Lower Liberty and Penn avenues are largely devoted to wholesale houses. Fourth Avenue is the local Wall Street, and here, as on other principal thoroughfares, are many splendid buildings. The residential portions of the city, being of recent development and less confined by natural boundaries, have wide, well-shaded streets, arranged with some regard for system. The most costly residences are in the Bellefield, Shadyside, East Liberty, and Squirrel Hill districts. Among the finer streets are portions of Fifth and Penn avenues, the chief thoroughfares between the downtown and East End districts; North Highland, Ellsworth, and Center avenues.

The city has about 450 miles of streets, of which 256 miles are paved, principally with asphalt or block stone. There are 323 miles of sewers, including 45 miles of brick. All the streets are covered by city water mains, save those on the South Side, which is supplied by a private company. Natural and artificial gas is piped to all parts of the city. For a decade previous to 1895 natural gas was the principal fuel in the mills and factories, but, owing to a decrease in the supply, the larger factories have been forced to resume the use of coal. Natural gas still forms the favorite fuel for domestic purposes. An extensive system of street railways, operated by electricity, connects the city with the surrounding towns. All the lines in Pittsburg and Allegheny and many of those reaching to the boroughs have been consolidated under one management.

BUILDINGS. Among the prominent public buildings are the Allegheny County court house and jail, erected in 1884 at a cost of \$4,000,000, granite structures facing on Fifth Avenue and connected by a 'Bridge of Sighs' across Ross Street. The post-office building on Smithfield Street is a splendid specimen of architecture. The rooms occupied by the United States Circuit and District courts are finished in mahogany, magnificently carved. The United States Engineer, Collector of Internal Revenue, Surveyor of the Port, and other Federal officials have their offices in this building. Chief among the many

handsome office buildings for which Pittsburg is noted is the Frick Building, at Fifth Avenue and Grant Street. It is of granite, 20 stories high, and finished throughout in marble and mahogany. It is one of the most luxurious public office buildings in the world. The Farmers' Deposit National Bank Building, 24 stories high, is little inferior. Among other handsome edifices of the 'skyscraper' type are the Carnegie, Park, Tradesmen's, Peoples' Bank for Savings, Arrott, and Empire. The Bank of Pittsburg and the Pittsburg Stock Exchange have artistic homes. Among the notable ecclesiastical structures are the new Saint Paul's Cathedral in Bellefield, Trinity Church (Protestant Episcopal), First and Third Presbyterian churches, Church of the Ascension (Protestant Episcopal), East Liberty Presbyterian, Christ Methodist Episcopal, Saint Augustine's (Roman Catholic), Sixth United Presbyterian, and Calvary (Protestant Episcopal). The finest hotels are the Schenley, Lincoln, and Henry.

PARKS. Pittsburg's system of parks originated in 1890, when Mrs Mary E. Schenley deeded to the city more than 400 acres of land in the heart of the residential district. This was named in her honor. Since that time the city has acquired several other tracts of land for park purposes, and the system now includes 1000 acres, all within the city limits. Additions to Schenley Park have increased its size to 440 acres. It contains the Phipps Conservatory and the Hall of Botany, both gifts from Henry Phipps; a music pavilion, several fine bridges, a bronze statue of E. M. Bigelow, the 'Father of the Parks,' a notable pair of panthers in bronze, and three shelter houses. Highland Park, one of the most picturesque parks in the country, has an area of 441 acres. It contains city reservoirs Nos. 1 and 2, zoölogical gardens, the gift of the late C. L. Magee, two shelter houses, and several statues. The principal entrances at Highland and Stanton avenues are graced by handsome sculptures. The other parks, all small, are: Herron Hill, Central, Friendship, Holliday, West End, Grandview, McKinley, and Second Avenue. Connecting Schenley and Highland parks with the downtown district are Grant and Beechwood boulevards, 10½ miles long, and forming, with the roadways in the parks, a continuous drive of more than 20 miles in length.

PUBLIC INSTITUTIONS. Chief among the public institutions of the city are the Carnegie Free Library and the Carnegie Institute, situated at the Forbes Street entrance to Schenley Park. They were presented to the city by Andrew Carnegie. The first tender was made in 1881, but it was not until 1886 that Councils accepted the offer. The building, for which Mr. Carnegie gave \$1,100,000, was completed in 1895. It contains the Central Free Library and the Carnegie Institute, the latter comprising a museum, gallery of fine arts, and music hall. The library and institute are affiliated, but not identical, the former being maintained by the city, while the latter has an endowment of \$2,000,000 from Mr. Carnegie. The city appropriates \$131,000 annually for the maintenance of the central and branch libraries. The central library contains 104,500 volumes, and five branches, in various parts of the city, have an aggregate of 55,500 volumes. In the gallery of fine arts are a permanent collection of 50 paintings, many of which

were bought at the annual exhibitions given there, 19 plaster casts of famous sculptures, and 170 reproductions of antique bronzes. The museum has a large collection of wide scope. In the music hall is a fine pipe organ, and here are given every week two free recitals. The hall is also the home of the Pittsburg Orchestra, which gives a course of concerts each winter. The music hall is self-supporting. The library and institute are to be much enlarged. The city has just acquired the necessary ground, and Mr. Carnegie has placed \$5,000,000 at the disposal of the trustees. The building will cover three and one-half acres.

The Pittsburg Exposition Society occupies a large building between Duquesne Way and the Allegheny River, at the Point. Here a general exposition is held each autumn, lasting for six weeks. The largest general hospital in the city is the West Penn. on Twenty-eighth Street, which has a department for the insane at Dixmont. Other large hospitals are the Mercy, Homeopathic, Saint Margaret's Memorial, Passavant, Charity, South Side, and Eye, Ear, and Throat. All these, save the last named and Saint Margaret's receive State aid. Among the charitable institutions are the Church Home (Protestant Episcopal), Saint Joseph's Protectory for Boys (Roman Catholic), Home for Incurables, Florence Crittenton Home, Home for the Aged (Roman Catholic), Free Dispensary, House of the Merciful Saviour, Saint Paul's Orphan Asylum (Roman Catholic), now located at Idlewood; Old Ladies' Home (United Presbyterian), at Wilkinsburg; Odd Fellows' Home for Widows and Orphans, at Ben Avon. The principal cemeteries are Allegheny, Homewood, and Southside (Protestant), and Saint Mary's and Calvary (Roman Catholic). The smaller burying-grounds are numerous, perhaps the most interesting being that surrounding Trinity Church, Sixth Avenue, where many of the prominent pioneers of the community repose.

EDUCATIONAL INSTITUTIONS. Pittsburg has a well-equipped educational system, which includes 86 ward and three high schools. In 1903 the number of teachers and principals was 1044, and the total enrollment of pupils 40,868. The expenditures for educational purposes were \$1,658,716. The control of the ward schools is vested in district school boards, the districts usually being coextensive with the wards. The Central Board of Education, composed of one representative from each district board, has direct control of the high schools and regulates the preparatory courses of study. Each district makes its own tax levy. The bonded indebtedness of the various school districts in 1903 was \$1,957,000. The Central Board annually appropriates money for kindergartens and summer schools, which are partly supported by civic societies. The private educational institutions of the city include the Pittsburg Academy, Pittsburg College of the Holy Ghost (Roman Catholic), Academy of Our Lady of Mercy (Roman Catholic), for girls, Bishop Bowman Institute (Protestant Episcopal), Pennsylvania College for Women, Shadyside Academy, Kindergarten College, departments of law, medicine, dental surgery, and pharmacy of the Western University of Pennsylvania, Institution for the Blind, and, in the suburb of Edgewood, the Institute

for the Deaf and Dumb; also numerous parochial schools.

In 1901 Andrew Carnegie offered to present to the city a free institute of technology. The offer was accepted, the city agreeing to furnish the site and maintain the school. In 1903 a site, costing \$350,000, was bought near the free library.

COMMERCE AND INDUSTRY. Pittsburg has been since its foundation the natural transfer point between the East and West. It is a port of entry, and its imports for the year ending March 31, 1903, amounted to \$1,504,705. The city's rapid growth, however, is due to its industrial activities, and these owe their supremacy to the abundant fuel supply. Coal and coke form the largest items in the immense freight tonnage of Pittsburg, a tonnage which surpasses that of New York and Chicago combined, and which has no equal in the world. The railroad freight for 1902 exceeded 80,000,000 tons, while the water tonnage approximated 9,500,000 tons. The manufacturing interests of the city date back to the close of the eighteenth century. Iron-working and glass-making were early engaged in, and glass and steel are still the leading products. According to the census of 1900 Pittsburg had invested in manufacturing within its municipal limits \$193,162,900, and the annual product was worth \$203,261,251. In adjoining cities and towns were plants with an invested capital of about two-thirds of the corresponding amount given above. The Greater Pittsburg produces annually 3,500,000 tons of pig iron, or about 22 per cent. of the entire output of the country. Finished products include wire, nails, boiler and hull plate, rails, angle iron, sheet, tinned sheet, tools, agricultural implements, stoves, engines, boilers, plumbing and sanitary supplies, enameled ware, electrical machinery, tubes, armor plate, projectiles, and air brakes. The manufactures of iron and steel have overshadowed the activities in other lines, which, however, are important. In 1900 the value of the glass product was \$2,778,847. The largest cork factory in the world is in Pittsburg. The output of manufactured copper is 500,000 pounds annually. In the production of electrical cable for underground use Pittsburg leads the country. Among other industries of importance are the manufacture of pottery, brick, shot and lead pipe, jewelry, asbestos, shoes, tobacco and cigars, mirrors, malt and spirituous liquors, clothing, oleomargarine, rubber, and aluminum. In these employments and others 69,977 workmen were engaged in 1900. The number of manufacturing establishments was 1938. A large business is done in petroleum products, several refineries being in the city.

The transportation facilities of Pittsburg include the Pennsylvania, Vanderbilt, and Gould systems of railways, the independent Pittsburg, Bessemer and Lake Erie, and Buffalo, Rochester and Pittsburg roads, and the rivers. The Pennsylvania system includes, from the east, the main line of the Pennsylvania Railroad, the Buffalo and Allegheny Valley division, the Pittsburg, Virginia and Charleston, the Baltimore and Ohio, and the West Penn; from the west, the Pittsburg, Fort Wayne and Chicago, the Erie and Pittsburg, the Cleveland and Pittsburg, the Pittsburg, Cincinnati, Chicago and Saint Louis, and the Pittsburg and Western roads, with their branches. The Vanderbilt system reaches the

city from the west by way of the Pittsburg and Lake Erie Railroad, while the Gould interests are penetrating to the city through an extension of the Wabash from the west. The most extensive freight yards are at Piteairn on the Pennsylvania Railroad, Versailles on the Baltimore and Ohio, McKee's Rocks on the Pittsburg and Lake Erie, Conway on the Pittsburg, Fort Wayne and Chicago, Sheridan on the Pittsburg, Cincinnati, Chicago and Saint Louis, and at Twenty-eighth Street on the Buffalo and Allegheny Valley division. The Pennsylvania system has a large union station at Tenth and Liberty streets, used by all its roads except the Baltimore and Ohio and the Pittsburg and Western. The Pittsburg and Lake Erie also has a fine new station on the South Side.

The rivers are of great importance commercially. The Monongahela runs through the richest coal fields of the Pittsburg district, and is improved throughout its entire length. In 1897 the Federal Government purchased seven locks and dams from the Monongahela Navigation Company for \$3,761,615. It already owned two locks and dams above these, and Congress soon afterwards authorized the construction of six more at a cost of \$1,200,000 to give slack-water navigation from Pittsburg to Fairmont, W. Va., a distance of 130 miles. Three locks and dams, to cost \$1,500,000, are under construction on the Allegheny River, which will give 22 miles of slack-water navigation. On the Ohio River, Davis Island dam, constructed at a cost of \$940,000, affords a harbor for the city. Six dams are being constructed at an estimated cost of \$5,525,000, and five more have been authorized by Congress. The project contemplates the creation of a nine-foot stage of water between Pittsburg and Cairo, Ill., at an ultimate cost of \$50,000,000. The traffic on these rivers is enormous, consisting chiefly of coal and manufactured iron. Of the 9,500,000 tons of freight on the rivers each year, 5,500,000 tons are coal. Pittsburg has 144 steam vessels, with a total tonnage of 39,476, on its marine register, but the barges, in which most of its shipping is done, are not registered. Their tonnage is estimated to be in excess of 2,500,000 tons. Considerable business in lighter freights and passengers is done on the Monongahela and Ohio rivers by fast packets. The Allegheny is devoted chiefly to lumber-rafting.

The export trade of Pittsburg is large and is growing rapidly. Coal is being shipped by river to New Orleans, and by rail to New York and Philadelphia for export. Manufactured iron and steel also are exported in immense quantities.

GOVERNMENT. The government of Pittsburg is vested in a mayor and a bicameral city council. The title of the chief executive was changed from mayor to recorder by an act of Legislature passed in 1901, regulating the government of second-class cities, and his powers were much enlarged, but in 1903 the former title was restored. He now appoints, with the consent of Select Council, the city treasurer, directors of the departments of public works, public safety, charities, and the department of law, as well as five police magistrates. Councils elect their own presiding officers and the city clerks. The comptroller is chosen by popular vote. The city has a pension fund for the benefit of veteran employees of the police and fire bureaus, and a dis-

ability fund for the assistance of those killed or injured while on duty. The police administration is, under the director of the department of public safety, in the hands of two coordinate bureaus, police and detectives. The fire department is under the control of a chief engineer. Its equipment is excellent, but the water supply at present is inadequate, and insurance rates are accordingly high.

MUNICIPAL FINANCES. The total assessed valuation of the city in 1903 was \$375,163,051. The gross bonded indebtedness was \$21,391,201, and the net debt \$15,740,838. The limit of indebtedness is fixed by law at seven per cent. of the assessed valuation. The real estate owned by the city, exclusive of school properties, is valued at \$17,406,206, the water plant forming the largest single item—\$5,969,300. The water supply is drawn from the Allegheny River, and is not good. The electors have authorized the construction of an extensive sand filtration plant from the proceeds of a bond issue. The parks are valued at \$3,436,835; the bureau of fire properties at \$815,000; the bureau of police properties at \$203,400; and the municipal hall at \$870,000. The total revenue of the city for the fiscal year ending January 31, 1903, applicable to general expenditure, was \$7,094,204. Of this sum the department of public works expended \$1,394,745, including \$235,000 for the repaving of streets. During the same period \$886,000 expended for the paving and sewerage of new streets was paid by the owners of abutting property. The department of public safety expended \$1,387,035, the principal items of which were for fire and police protection. The department of charities maintains a city farm at Marshalsea, and on this and for outside relief expended \$131,352. The appropriation for interest and sinking fund was \$1,595,834. The city maintains a municipal hospital for contagious diseases, and was one of the first in the country to engage in the production and free distribution of diphtheria antitoxin serum.

POPULATION. The growth of Pittsburg during the past few decades has been very rapid. In 1900 the city's population was 321,616. In 1800 it was but 1565. The population by succeeding censuses follows: 1810, 4768; 1820, 7284; 1830, 12,542; 1840, 21,115; 1850, 46,601; 1860, 49,221; 1870, 86,076; 1880, 121,799; 1890, 238,617. Of the population in 1900, 236,738 were native born and 84,878 foreign born, while 171,225 were of foreign parentage. The preponderance of the iron and steel industries draws a large foreign population to the city and vicinity. The colored population is large, in 1900 having been 17,195.

HISTORY. As early as 1730 the confluence of the Allegheny and the Monongahela rivers became a centre of trading operations with the Indians. France and England were rival claimants to the region, and on the English side both Pennsylvania and Virginia asserted jurisdiction. While on his mission to warn the French away from the Allegheny Valley, Washington visited the site of Pittsburg in November, 1753. He wrote in his journal: "I spent some time in viewing the rivers and the land in the forks, which I think extremely well situated for a fort, as it has absolute command of both rivers." In the interest of the Ohio Company (q.v.), Captain Trent, with a few Virginia militia, began to build a fort at this place, in February, 1754. On

April 17th a force of 700 French and Canadians forced the Virginians to leave. The works were completed and enlarged by the French and named Fort Duquesne. In an effort to retake the place a strong British expedition under General Braddock met disastrous defeat at the hands of the French and Indians, eight miles from Fort Duquesne, on July 9, 1755. In 1758 General Forbes, moving from Philadelphia, led an army of 7500 against Fort Duquesne. A party of 800, under Major James Grant, attempted to surprise the fort on the morning of September 14th, but was overwhelmed and routed. The site of this defeat is a hill in the business centre of the city, now occupied by the Court House and the Frick Building. Forbes by November 24th was within fifteen miles of Fort Duquesne. The French then burned the fort and fled. Forbes occupied the place on November 25th and named it "Pittsburgh," in honor of England's Prime Minister. A small garrison remained over winter, and in 1759 General Stanwix constructed Fort Pitt. During Pontiac's war in 1763 the fort was vigorously besieged by the Indians from June 27th to August 6th. Col. Henry Bouquet, with 500 British regulars, marched from Carlisle to the relief of the fort, defeated the Indians at Bushy Run, 30 miles east of Pittsburg, after a two days' fight, and reached the fort on August 9th. In 1764 Bouquet erected a brick block-house a short distance from the fort, and this is the only structure of colonial times remaining at Pittsburg. It is owned and preserved by the Daughters of the American Revolution.

In 1768 John Campbell laid out a small plan of lots near the fort, whereon cabins were erected by sufferance of the fort's commander. The title to the country surrounding Pittsburg was bought from the Iroquois in 1768, and in April, 1769, the Penns opened a land office, but sold nothing within the manor of Pittsburg. Titles under Pennsylvania were not popular, but a strong emigration set in from Virginia. Washington, on a journey down the Ohio River to seek bounty lands for his soldiers, visited Pittsburg in October, 1770. He then wrote: "The houses, which are built of logs, and ranged in streets, are on the Monongahela, and I suppose may be about twenty in number and inhabited by Indian traders." In 1772 Fort Pitt was evacuated by the British, but two years later it was occupied by Virginia militia and Virginia authority was established. Virginia courts were held in Pittsburg in 1775-76 and Virginia governed the country until the boundary dispute was adjusted in 1781. During the Revolution Fort Pitt was garrisoned by Continental troops, who were occupied in frequent excursions against the Indians. The Penns began the sale of lots in the manor of Pittsburg in 1784, in which year Arthur Lee thus described the place: "Pittsburgh is inhabited almost entirely by Scots and Irish, who live in paltry log houses. There are in the town four attorneys, two doctors, and not a priest of any persuasion, nor church, nor chapel, so that they are likely to be damned without the benefit of clergy. The place, I believe, will never be very considerable." Allegheny County was erected in 1788, and the court house was established at Pittsburg. The opening of the Northwest Territory gave an impetus to trade, but Pittsburg's real growth did not begin until the close of Indian hostilities in 1795. In 1794

Pittsburg took an active part in the Whisky Insurrection (q.v.), houses being burned, large meetings of the disaffected held, and destructive fires, supposedly incendiary, breaking out, so that troops had to be sent here to enforce the law. Pittsburg became a borough in 1794 and a city in 1816. In 1796 its population was but 1400. The making of window glass began in 1796, and during the first ten years of the nineteenth century ship-yards, foundries, the first bank, cotton factories, and shops for metal-working came into existence. The Pennsylvania Canal was opened to Pittsburg in 1834, and the era of activity and prosperity that followed was only temporarily checked by the fire of 1845, which destroyed property valued at \$6,000,000. In 1877, during the great railroad strike, property valued at more than \$3,000,000 was destroyed by the rioters.

PITTSBURG. A city in Crawford County, Kan., 130 miles south of Kansas City; on the Atchison, Topeka and Santa Fe, the Missouri Pacific, the Saint Louis and San Francisco, and the Kansas City Southern railroads (Map: Kansas, II 4). It has extensive coal-mining interests, being situated in the centre of productive coal fields and near the great mineral district of southwestern Missouri. There are also shops of the Kansas City Southern, a foundry and machine shops, brick and sewer pipe plants, lumber and flour mills, grain elevators, a packing house, etc. The city maintains a public library. Settled in 1876, Pittsburg was incorporated in 1880. It is governed by a mayor, elected biennially, and a unicameral council. Population, in 1890, 6697; in 1900, 10,112.

PITTSBURG LANDING, BATTLE OF. See SHILOH, BATTLE OF.

PITTSBURG ORCHESTRA. The permanent orchestra of Pittsburg, Pa. It was founded in 1895, and is maintained by public subscriptions guaranteed by a few public-spirited citizens. It has a membership of about seventy, and ranks with the great orchestras of America. Frederick Archer was its first conductor. In 1898 Victor Herbert became its conductor and brought the organization to a high degree of efficiency.

PITTSFIELD. A city, including several villages within its corporate limits, and the county seat of Berkshire County, Mass., 150 miles west of Boston; on the Boston and Albany and the New York, New Haven and Hartford railroads (Map: Massachusetts, A 3). Its site in a hill-girt valley of the Berkshires, over 1000 feet above sea level, is of great natural beauty. In the vicinity are several picturesque lakes. There are public parks, one of which, in the heart of the city, has the fine statue of "The Color Bearer." Among the noteworthy structures are the court

house, built of white marble, the Crane Art Museum, the Berkshire Athenaeum, the latter containing a public library of 36,000 volumes and the rooms of the Berkshire Historical Society; the House of Mercy and the Henry W. Bishop Training School for nurses, and the Berkshire County Home for Aged Women; the high school, the Berkshire Life Insurance Building, and the Berkshire County Savings Bank. The city is the headquarters of the Agassiz Association (q.v.). Pittsfield is an attractive residential place and a popular summer resort. It is known also for its manufacturing interests. As shown by the census of 1900, \$6,085,000 was invested in the various industries, which had a production valued at \$7,136,000. The leading establishments are woolen mills, a silk mill, foundry and machine shops, shoe factory, works making electrical machinery and supplies, paper mills, etc.

The government, under a charter of 1895, is conducted by a mayor, chosen annually, and a bicameral council that elects most administrative officers. The school committee is chosen by popular vote. The mayor appoints license commissioners. The water-works are owned and operated by the municipality. Settled in 1743 as Pontoosuck or Boston Plantation, Pittsfield was incorporated as a town under its present name in 1761 and in 1891 was chartered as a city. Longfellow stayed for a time at the Appleton House here and Oliver Wendell Holmes and Herman Melville lived in the vicinity. Population, in 1890, 17,281; in 1900, 21,766. Consult Smith, *The History of Pittsfield* (Boston, 1876).

PITTS/TON. A city in Luzerne County, Pa., ten miles southwest of Scranton; on the Susquehanna River, above the mouth of the Lackawanna, and on the Lehigh Valley, the Central of New Jersey, the Delaware and Hudson, the Lackawanna, and other railroads (Map: Pennsylvania, F 2). Situated in the anthracite region of the State, it is engaged principally in mining and preparing coal for market, the coal traffic being very important. There are also valuable deposits of fire clay in the vicinity. The manufacturing establishments include foundries and machine shops, stove and engine works, knitting mills, flour, paper, and lumber mills, breweries, terra-cotta and brick works, etc. Pittston is one of the leading commercial and industrial centres of this region. West Pittston (q.v.), across the river, is more distinctly a residential section. The city maintains a public library. Laid out in 1768 and named in honor of William Pitt, Pittston was settled about 1770, was incorporated as a borough in 1803, and was chartered as a city in 1894. Population, in 1890, 10,302; in 1900, 12,556.

PITUITARY BODY (Lat. *pituitarius*, relating to phlegm, from *pituita*, phlegm; connected with *spuere*, Gk. *πρῦεν*, *ptyein*, Lith. *spiauti*, Lett. *splaut*, OChurch Slav. *plivati*, *plynti*, Goth. *speivan*, OllG. *spūvan*, Ger. *speien*, AS. *speican*, Eng. *spue*, and ultimately with Eng. *spit*). The hypophysis of the brain, often called the pituitary body, is an appendage of the lower side of the twixt-brain in vertebrates. Its origin shows that it is a compound body, the different parts of which arise from different areas in the embryo. When fully developed the pituitary body consists of three parts, a stalk, an anterior and

a posterior lobe. This stalk arises as an evagination of the floor of the 'twixt-brain and is called the infundibulum. Its distal portion subsequently develops into the posterior lobe. In the lower vertebrates the stalk and posterior lobe are clearly made up of nervous tissue, but in the higher animals the posterior lobe contains very little nervous substance. The anterior lobe arises as an evagination or outgrowth of the upper surface of the mouth, and only secondarily comes into connection with the other parts. It has a very characteristic structure, contains no nervous elements, and resembles very closely a ductless gland. In no living vertebrate does the hypophysis have any known function, and even if it be granted that it is homologous with the subneural gland of tunicates, its actual use to the animal, either past or present, would still be an open question. Numerous theories have been proposed to account for its structure and function, but none have met with very general acceptance. The most recent (1903) is that the pituitary body is in intimate nervous connection with the suprarenal capsules, and through them regulates the amount of oxygen absorbed by the blood. But this view is not adequately supported by clinical or experimental evidence.

PIT VIPER. See CROTALIDÆ.

PIT'YRIASIS (Neo-Lat., from Gk. *πυρραία*, *pityriasis*, from *πυρον*, *pityron*, bran). An exfoliation of the skin in bran-like scales, regarded by some dermatologists as a condition occurring in several skin disorders, by others as a separate disease. Excessive formation of dandruff (*furfuracea*) is called *pityriasis simplex* or *pityriasis capitis*, or *pityriasis of the scalp*, by some. The popular skin affection known as *pityriasis* embraces four varieties: (1) *Pityriasis rubra* is characterized by a gradual dissemination of papules over the trunk and upper extremities, especially upon the dorsal aspect of forearms and phalanges. The papules are bright red and slightly brownish, and are succeeded by large red spots or plaques. Changes occur in the surface of the skin incident to the scratching which the itching necessitates. (2) *Pityriasis rosca* is similar to *pityriasis rubra*, with perhaps greater infiltration of the skin, although the erythema is less. A macular form is also described. (3) *Pityriasis nigra* has been observed in children born in India and brought to England. The eruptive papules are black. (4) *Pityriasis versicolor*, or *tinea versicolor* (q.v.), is characterized by the occurrence of brown or dark yellowish patches over the trunk, and is confined to the body, where it is covered by clothing. It is due to a parasite, the *Microsporon furfurans*.

Pityriasis infantilis and *pityriasis scnilis* are forms of eczema (q.v.). *Pityriasis tabescentium* is seborrhæa (q.v.). The treatment of these diseases must be left to a physician. Consult Kaposi, *Pathology and Treatment of Diseases of the Skin* (New York, 1895).

PIT'YU'SÆ. The southwestern group of the Balearic Islands, consisting of the islands of Iviza and Formentera (qq.v.) and a number of small, uninhabited islets.

PI-TZŪ WO, pē'tsōō wō'. A small seaport on the east coast of the peninsula of Liao-tung (q.v.). It lies north of Ta-lien-wan, in latitude 39° 18' N., and longitude 122° 18' E.,

has many large warehouses and considerable trade, and is included in the territory leased by Russia along with Port Arthur (q.v.). The harbor is well sheltered by a semicircular reef, but is shallow.

PIURA, pē-ōō'rā. The northernmost department of Peru, bounded by Ecuador on the north, the Peruvian Department of Amazonas on the east, Cajamarca and Lambayeque on the south, and the Pacific Ocean on the west (Map: Peru, A 5). The area is estimated at 16,825 square miles. The eastern part is mountainous, with fertile valleys; the western is mostly desert land. Cotton is grown to some extent and some minerals are found, of which the petroleum deposits are exploited. The population was officially estimated in 1896 at 213,900. The capital is Piura (q.v.).

PIURA. The capital of the Department of Piura, Peru. It is situated 20 miles from the coast and 80 miles southeast of Cape Blanco (Map: Peru, A 4). It is a well-built town with a beautiful garden-plaza containing a marble statue of Liberty. It is an important cotton market, and is connected by a railroad with the port of Payta (q.v.). Population, about 12,000. Piura was the first permanent settlement made by Pizarro.

PI'US. The name of ten popes. PRUS I., Saint, Pope 140-154. Little is known of his pontificate; perhaps the most authentic record of it is that contained in the Muratorian Fragment, which assigns the writing of the *Shepherd* by Hermas, his brother, to his pontificate. See HERMAS, SHEPHERD OF.—PIUS II., better known generally as Æneas Sylvius, Pope 1458-64. He came of the noble family of Piccolomini in Siena, and was born in 1405 in the village of Corsignano, afterwards called Pienza from his Papal title. His early life was not free from serious irregularities, but he made amends by his subsequent decorous conduct; and his eminent abilities as a canonist led to his being employed, when but twenty-six years of age, as secretary to the Cardinal-Bishop of Fermo, an appointment which, though it lasted but a short time, led to further employment and brought him commissions of the highest importance in connection with the Council of Basel (q.v.). On the election of the antipope Felix V. (Duke Amadeus VIII. of Savoy), in 1439, he was chosen one of the deputation to notify him of his election, and became his secretary, in which post his eminent literary abilities were conspicuously useful. Having been sent as ambassador to the Emperor Frederick III., he was induced to accept office in the Imperial Chancery. This opened the way for further steps in the diplomatic career of which his prudence took advantage. On a mission to Rome in 1445 he declared himself decidedly for Eugenius IV. and attached himself to his interests. Having at last decided to take holy orders in that year, he was made Bishop of Triest in 1447 and of Siena in 1449, remaining, however, in the Imperial service until 1455. A year later he was made a cardinal by Calixtus III. On the death of this pontiff, in 1458, after a conclave lasting only three days, Æneas Sylvius was elected his successor. As Pope he devoted himself to rousing Christendom to a war against the Turks. He called a congress of princes to meet at Mantua in 1459, and appeared in person to preside over

it, but little came of it for the time. Undeterred by discouragements, he pursued his purpose, and had planned to go in person against the Turks; but, seized with illness at Ancona, where the fleet was to assemble, he died August 14, 1464. The literary reputation of Aeneas Sylvius has partially eclipsed the historical fame of the Pope. He was one of the most eminent scholars of his age, in many ways a type of the Renaissance learning. The most interesting portion of his works is the collection of his letters, which are full of details characteristic both of the writer and of his age. He left also some partly autobiographical commentaries (republished by Lesca, Rome, 1894). Others of his works, the novel *Lucretius et Eurypalus* and his dialogues on the authority of general councils and in defense of the Council of Basel, he formally retracted. Consult his *Life* by G. Voigt (Berlin, 1856-63); by Weiss (Graz, 1897); and an essay on him in Creighton, *Historical Essays and Reviews* (London, 1902).

PIUS III., Pope 1503, Francesco Todeschini. He was a nephew of Pius II., who made him Bishop of Siena and cardinal in 1460. He was employed by subsequent popes in various important missions, and succeeded Alexander VI., but only lived a month after his election.—PIUS IV., Pope 1559-65, Giovanni Angelo Medici or Medeghino. He was born in 1499, studied medicine and law, and devoted himself to the latter as a profession. Later he went to Rome and entered on an ecclesiastical career, being named archbishop (1545) and cardinal (1549) by Paul III. Elected Pope after a conclave lasting more than three months, he entered upon a heritage of many troublesome questions. The principal significance of his pontificate lies in his reassembling of the Council of Trent, which Paul IV. had thought to have practically completed its task. It was finally closed, after further sessions lasting over nearly two years, in December, 1563, and the bull confirming its decrees was issued January 26th following. The well-known creed called the Creed of Pius IV. or the Tridentine confession of faith was issued by Pius as an embodiment of all the doctrines defined in the council. (See PIUS IV., CREED OF.) Pius exerted himself vigorously to carry out the reforming decrees of the council, though much of this work was reserved for the following pontificate. He died December 9, 1565, in the arms of his nephew, Charles Borromeo (q.v.), whom he had made a cardinal.—PIUS V., Saint, Pope 1566-72, Michele Ghislieri. He was born in 1504 at Bosco, near Alessandria, entered the Dominican Order at fourteen, and after the completion of his studies was employed in various capacities, educational and administrative. Paul IV. made him Bishop of Sutri in 1556, cardinal in 1557, and grand inquisitor in 1558. His main task as Pope was to enforce the reforming decrees of the Council of Trent. Auster and self-denying in his personal life, he expected equal devotion on the part of others, and met opposition with unflinching firmness. He republished the bull *In vena Domini* (q.v.) in a more rigorous form, and excommunicated and attempted to depose Elizabeth of England for her refusal to submit. The resources of the Papacy were employed to assist the Catholic cause against the Huguenots in France and to protect Christendom from the Turks. With Spain and Venice, Pius organized the Holy League against the Turks, who were signally defeated in the

naval battle of Lepanto. He completed the Roman catechism, and published thoroughly revised editions of the missal and breviary. He was canonized by Clement XII. in 1712. Consult Falloux, *Histoire de saint Pie V.* (3d ed., Paris, 1858).

PIUS VI., Pope 1775-99, Giovanni Angelo Braschi. He was born of an impoverished but noble family in 1717, and early entered the ecclesiastical service, being made a cardinal in 1773 by Clement XIV., whom he succeeded two years later. He maintained the position of the Church with uncompromising firmness against the Emperor Joseph II. and his brother, Leopold I. of Tuscany (afterwards Emperor Leopold II.); but his greatest troubles came from the aggressions of the French Republic. In 1793 a popular tumult in Rome, which was caused by the imprudence of a French political agent named De Basseville, and resulted in his death, gave the Directory some years later an opportunity for hostile demonstrations. In 1796 Bonaparte took possession of the legations and afterwards of the March of Ancona, and by a threatened advance upon Rome extorted from Pius, in the Treaty of Tolentino (February, 1797), the surrender of these provinces, which were constituted part of the Cisalpine Republic. Finally the Directory ordered an advance upon Rome; Berthier entered the city February 10, 1798, where the Roman Republic was proclaimed, and ten days later the Pope, refusing to renounce his temporal sovereignty, was seized and carried off to Siena and later to the Certosa near Florence. On the threatened advance of the Austro-Russian army in the following year, he was transferred to Grenoble, and finally to Valence on the Rhone, where, worn out by age and the rigor of confinement, he died, August 29, 1799, after the longest pontificate until then recorded.

PIUS VII., Pope 1800-23, Gregorio Luigi Barnaba Chiaramonti. He was born at Cesena in 1742, and entered the Benedictine Order at the age of sixteen, and was employed in teaching philosophy and theology at Parma, and afterwards at Rome. He was appointed Bishop of Tivoli, and in 1785, being created cardinal, was transferred to the See of Imola. Upon his election to the Papacy in 1800, Rome was restored to the Papal authority, and in July of that year Pius VII. entered his capital; and in the following year the French troops were withdrawn from the Papal territory, with the exception of the legations. From this time forward Pius, ably seconded by his Secretary of State, Cardinal Consalvi, was destined to occupy a prominent place in the political as well as the ecclesiastical affairs of Europe. Bonaparte had resolved to restore religion in France on the ancient basis of connection with Rome. With this view, he entered into negotiations with Pius VII. for the establishment of a concordat suited to the new order of things which had arisen. It was agreed to at Paris, July 15, 1801; ratified in Rome, August 14th; and published in Notre Dame on Easter Sunday, 1802. But, simultaneously with the concordat, and as if forming part of the same arrangement, was published a code of what were called 'organic laws,' seriously affecting the discipline of the Church with regard to marriage, the clergy, and public worship, which had never been submitted to Pius, and to which he not only had not consented, but to

which he found himself compelled to offer every opposition. For the first year which succeeded the publication of the concordat, no occasion of difficulty arose; but conflict of principles was in the end inevitable. In 1804 Bonaparte, having resolved on assuming the Imperial crown, invited Pius to come to Paris for the purpose of crowning him, and the Pope, although with much hesitation, consented. He took advantage of his visit to demand the recall or modification of the articles of the code, but without success; and although, during his visit to Paris, he was treated with great distinction and reverence, his relations with Napoleon from that date began to assume a less friendly character. The French Emperor now proceeded from one petty outrage to another, until finally, in February, 1808, the French troops, under General Miollis, entered Rome and took possession of the Castle of Sant' Angelo, and on April 2d a decree was issued annexing the provinces of Ancona, Fermo, Urbino, and Macerata to the Kingdom of Italy. Pius, besides protesting against the usurpation, declared himself a prisoner in the French hands, and confined himself to his palace. Finally (May 17, 1809) the usurpation was consummated by a decree annexing Rome and all the remaining Papal territory to the French Empire. This was the signal for the Pope abandoning his policy of forbearance. On June 10th Pius issued a bull of excommunication, directed (without naming Napoleon) against the perpetrators and abettors of the invasion of the rights and the territory of the Holy See. Soon afterwards the French Emperor ordered the removal of the Pope from Rome; and Pius, without offering any resistance beyond the declaration that he yielded to force, was removed, first to Florence, then to Grenoble, thence for a longer time to Savona, whence, in June, 1812, he was finally transferred to Fontainebleau. During this prolonged captivity Pius firmly but quietly resisted every effort to compel or seduce him from his policy. At Fontainebleau he was treated with much external respect; and on Napoleon's return from the Russian campaign, in December, 1812, orders were given that the cardinals, with certain exceptions, should be admitted to the presence of the Pope. Under much pressure, both from the Emperor himself and from the ecclesiastics to whom the Emperor confided his plans, Pius was induced to sign a new concordat, an important provision of which was the recognition of the annexation of the Roman States to the Empire. Having obtained the concession, Napoleon at once permitted the absent cardinals to return, and of these many remonstrated so earnestly against the concordat that, on March 24th, Pius wrote to revoke his consent. Napoleon took no notice of the revocation; nor was it till after the disasters of 1813 that he began to seek an accommodation. Pius refused to treat until he should be restored to Rome; and on January 22, 1814, orders were sent for his immediate return to his capital. Unattended by his cardinals, he was escorted to Italy, and remained at Cesena until the campaign of the spring of 1814 placed Paris in the hands of the Allies, when Pius reentered Rome amid the gratulations of the people. During the Hundred Days he was again compelled to leave it; but, after the campaign of Waterloo, he finally resumed possession, which was undisturbed for the rest of his life, and extended to

the whole of the ancient territory, including the legations. His last years were devoted to measures of internal administration, and marked by much wisdom and moderation. Pius repressed with great vigor the disorder and brigandage which the long wars had encouraged, and the secret societies, especially that of the Carbonari (q.v.). In 1814 he formally restored the Order of Jesuits (q.v.). His private life was a model of gentleness, simplicity, and benevolence. Consult his *Life* by Mary Allies (London, 1901); Cardinal Pacea's *Historical Memoirs* (Eng. trans. by Sir George Head, London, 1850); Artaud, *Histoire du pape Pie VII.* (2 vols., Paris, 1836); D'Haussonville, *L'église romaine et le premier empire* (5 vols., 5th ed., Paris, 1870); Celani, *Il viaggio di Pio VII. a Parigi* (Rome, 1893).—PIUS VIII., Pope 1829-30, Francesco Xaverio Castiglioni. He was born at Cingoli, near Ancona, in 1761. He held in succession the bishoprics of Montalto, Cesena, and Frascati, and was made cardinal in 1816. During his brief pontificate he opposed the slave-trade in Brazil, civil marriages in Prussia, and the attacks on the Church emanating from Freemasons and Bible societies. Consult: Artaud, *Histoire du pape Pie VIII.* (Paris, 1844); Wiseman, *Recollections of the Last Four Popes* (London, 1858).

PIUS IX., Pope 1846-78, Count Giovanni Maria Mastai-Ferretti. He was born at Sinigaglia, May 13, 1792, and intended to enter the Papal Guards, but symptoms of an epileptic tendency caused him to abandon a military life. He took holy orders, and became Archbishop of Spoleto in 1827, Bishop of Imola in 1832, and cardinal in 1840. He was elevated to the Papal chair on June 16, 1846, two weeks after the death of Gregory XVI. Pius IX. took hold of the reins of government in the pontifical dominions, imbued with a sense of the evils, political, economic, and social, under which his semi-medieval realm had been laboring, and with a patriotic desire to raise Italy from her political degradation. He entered at once on a course of reforms, resolving to extirpate all abuses of administration in his State, to secularize the local administration, and to extend the rights of self-government. His first steps were to dismiss his Swiss guards and to grant a general amnesty. The latter measure unfortunately had the effect of bringing together a body of men whom exile had imbittered against the existing state of things. The Pope extended his innovations to every department of the administration, not sparing the ecclesiastical institutions and the clergy. At the same time he exerted himself strenuously to improve the economic condition of his people, and to promote their intellectual progress. His subjects were permitted to make their voice heard in public assemblies and in the press. His policy awakened enthusiasm among the friends of progress throughout Europe, Protestants and Jews, as well as Roman Catholics. Pius IX. was inspired with the dream of a free Italy, and sought to realize the ideal set forth by Gioberti of a federated Italy under the moral primacy of the Pope. But the programme which he embraced was far from satisfying the demands of the revolutionary party represented by Mazzini and his followers, and Austria was ready to combat with force of arms

a policy which threatened to subvert her dominion in Italy.

In April, 1847, the Pope announced the institution of a *consulta*, an advisory body consisting of deputies from the provinces. When it assembled in November, Pius IX. found that he had created a mouthpiece of radical demands, vehemently set forth and backed by the populace, which he was utterly unable to satisfy. A few months later the February Revolution of 1848 overthrew the Orleanist monarchy in France, and the Papal States were borne along on the flood of revolution which swept over Europe. Pius IX. was forced, while yet unprepared for it, to grant a regular constitution to his subjects, which was promulgated on March 14, 1848. It was an anomalous creation, providing for a triple machinery of legislation—a consistory of cardinals, an advisory council appointed by the Pope, and a Parliament of two chambers. A few days after this event Lombardy and Venice rose against the Austrians, and Charles Albert, King of Sardinia, embarked upon a war for the liberation of Italy. Pius IX. was dragged against his will into a struggle with the House of Hapsburg, which was to prove utterly futile. On June 11th the Papal forces were compelled to surrender to the Austrians at Vicenza. On July 25th the King of Sardinia met with disaster at Custoza. The revolutionary elements now obtained complete mastery in Rome. On November 15th the Pope's Prime Minister, Count Rossi, was assassinated as he was about to open the session of the Parliament. Violent demonstrations took place daily to compel the Pope's assent to measures which he repudiated. He at first confined himself in the Quirinal, and on November 24th fled secretly from Rome, taking refuge in the Neapolitan fortress of Gaeta. A republic was proclaimed in Rome in February, 1849. Pius IX. from his exile addressed a remonstrance to the various sovereigns. In April a French expedition, sent to restore the Papal authority, landed at Civitavecchia, which surrendered on July 2d, after a month's siege. The Pope's government was re-established, and in 1850 he again entered upon the administration. He now declared that, in view of the unsettled condition of Italy and the failure of many of his early measures of improvement, he could not proceed with the reforms which he had contemplated. With Cardinal Antonelli as Secretary of State, the course of the Papal Government became intensely reactionary. In 1860, after the war for the unification of Italy, the Romagna, the Marches, and Umbria were annexed to the dominions of Victor Emmanuel, but Pius persistently refused to cede any portion or to enter into any compromise.

His ecclesiastical administration continued very active, and proceeded upon the strongest assumption of the right of independent action on the part of the Church. He re-established the hierarchy in England, sanctioned the establishment in Ireland of a Catholic university, and condemned the principles upon which the Queen's colleges in that country were constituted. He concluded with Austria a concordat much more favorable to Church authority than the existing ecclesiastical laws had permitted. (See CONCORDAT.) In 1854 he issued a decree propounding as a doctrine of the Church the dogma of the Immaculate Conception (q.v.) of the blessed

Virgin Mary. The most important event of his pontificate was the convocation of the Vatican Council (q.v.), at which bishops from all parts of the Catholic world assembled in December, 1869. This was the first Church council since that of Trent had crystallized Roman Catholic dogma and practice to meet the Reformation attack. It was adjourned in July, 1870, after it had proclaimed the decree of the infallibility (q.v.) of the Pope when on a subject of faith or morals he issues a decree *ex cathedra* to the universal Church. Soon after the adjournment, the Italian army occupied Rome, which was made the capital of the Kingdom of Italy. Pius renewed with all solemnity his oft-repeated protest, and, refusing all proposals of accommodation, from that date declared himself a captive in the Vatican, to which he strictly confined himself until his death, February 7, 1878. Consult: Pugeois, *Histoire de Pie IX.* (Paris, 1877-86); and *Lives* by Maguire (London, 1878) and Shea (New York, 1878).

PIUS X., Pope 1903—, Giuseppe Sarto. He was born at Riese, near Venice, June 2, 1835, in a humble station, his grandfather having been a soldier in the Papal army under Gregory XVI. His whole life, until his elevation to the Papacy, was passed in Northern Italy. He studied at Treviso and at Padua, and was ordained priest in 1858. His faithful performance of his parochial duties won the favor of his superiors and caused his appointment as chancellor of the diocese in 1875 and vicar-capitular two years later. In 1884 Pope Leo XIII. named him Bishop of Mantua, and in 1893 created him cardinal and Patriarch of Venice. His appointment to the patriarchate gave rise to an animated dispute with the Italian Government, which claimed the right, as the successor of the Republic of Venice, to nominate the Patriarch. This claim was denied by the Holy See, and Monsignor Sarto's personal qualities finally gained the approval of the Government. In the administration of his important diocese he proved himself a strong and competent prelate, reforming a number of abuses which had crept in in the course of time. He won the veneration of all his people, especially by his devotion to the poor and the modesty and simplicity of his life. He was elected Pope on August 4, 1903, after six fruitless ballots had been taken, by fifty-five out of sixty-one votes, his two leading competitors having been Cardinals Rampolla (q.v.) and Gotti (q.v.). He entered upon his pontificate with the reputation, not only of a deeply religious man and a wise administrator, but of a learned scholar and friend of the arts. It was through him that Don Luigi Perosi, the priest composer, was first brought to public attention. The fact of his assuming the name of Pius was taken as an indication that he intended to maintain the generally conservative policy of Pius IX., and to continue the protest of his two predecessors against the occupation of the Papal States by the Italian Government, despite the fact that his personal relations with the House of Savoy had been uniformly friendly.

PIUS IV., CREED OF. The dogmatic formula drawn up by a commission of members of the Council of Trent as a summary of its decisions, and promulgated by Pope Pius IV. at the end of 1564 in the bull *In sacrosancta*. Its formal acceptance is required of all priests and teachers

in the Roman Catholic Church, as well as of all converts to that communion. It begins by embodying the Nicene Creed, and proceeds to the later more elaborate definitions. Successive articles declare belief in apostolical and ecclesiastical traditions and all other observances and constitutions of the Holy Roman Church; the Holy Scriptures according to that sense which the Church has held and does hold; seven sacraments of the new law instituted by Christ and necessary for the salvation of mankind, though not of every one; the definitions of the Council of Trent concerning original sin and justification; the doctrine of a true, proper, and propitiatory sacrifice in the mass, transubstantiation, and the reception of Christ whole and entire under either kind; a purgatory, the souls detained in which are helped by the prayers of the faithful; the veneration and invocation of the saints reigning together with Christ, and the veneration of their relics and of sacred images; the power and use of indulgences; and the position of the Holy Catholic Apostolic Roman Church as the mother and mistress of all churches. It concludes with a promise of fidelity to this faith and of obedience to the Bishop of Rome, successor to Saint Peter, Prince of the Apostles and Vicar of Jesus Christ. Its full text may be found in Schaff, *Creeeds of Christendom* (New York, 1877-78).

PIUS IX., ORDER OF. A Papal order of merit with two classes, founded by Pius IX. in 1847. It is conferred on the nobility for virtue and merit. The decoration is an eight-pointed blue star with gold flames between the arms. The device is *Virtuti et Merito*. Members of the order have a dark-blue uniform embroidered in gold. See Plate I. of ORDERS.

PIUTE. A name loosely applied to various small bands of Shoshonean stock (q.v.), scattered over the arid region between the Rocky Mountains and the Sierras, from the Colorado almost to the Columbia, in Nevada, northwestern Arizona, eastern California and Oregon, western Utah, and southern Idaho. According to Powell, who took a census of the bands in 1873, the name properly belongs only to those living in or adjoining southwestern Utah, while those now gathered upon Pyramid Lake and Walker River reservations in Nevada, popularly and officially recognized as Piute, are really of another tribe and language, which he calls Paviotso. Still others he classes with the Shoshoni and Banak. As there is practically no tribal cohesion, and but few cultural differences among the various bands, the only classification must come from a close study of the dialects. A few bands, as the Chemehuevi along the Colorado in northwestern Arizona, and the Mono in the Sierras of eastern California, have acquired a separate tribal recognition. Those of Oregon and the north are frequently known also as Snakes. See SHOSHONI. The meaning of the popular name is unknown; they themselves pronounce it in three syllables, *Pai-u-ti*. Those on Walker River Reservation, and probably the others as well, designate themselves by the common Shoshonean term *Nūma*, 'People.'

Living in a country too barren, as a rule, for agriculture or large game, the Piute subsisted chiefly upon wild seeds, berries, and roots, grasshoppers, and jack rabbits, with fish and ducks from the few scattered lakes. Their houses

were the so-called *wikiups*, low, dome-shaped or elliptical structures open at the top, covered with mats woven from rushes, and equipped with a variety of well-made baskets, but otherwise destitute of furnishing. They formerly went nearly naked, excepting in the coldest weather, when they wrapped around their bodies thick blankets woven from jack-rabbit skins cut into strips with the hair left intact. Their ordinary weapons were the bow and arrow and club. They did not use the lance or shield, and very few owned horses. The dead were usually cremated. Although stolid and apparently of low mental type as compared with the Plains tribes and their kindred, the Banak and Ute, they seem to hold their own well in the presence of civilization, and several of their men have at different times acquired reputation and influence far beyond their own boundaries. The Ghost Dance religion, the greatest Indian religious movement of modern times, originated among the Piute of Walker River Reservation. Some of the bands were hostile up to 1864, since which time treaties of peace have been made and a large number assigned to reservations. As a people they are now efficient workers among the whites, avoid the vices of civilization, wear citizen's dress, are healthy and apparently increasing. Those officially designated as Piute are in California, near Fort Bidwell, 200; in Oregon, Klamath and Warm Springs agencies, 185; in Utah, near Saint George, 100; in Nevada, Pyramid Lake, Walker River, and Wester, Shoshoni agencies, 1300; "not under an agent," about 3700.

PIXIS, pik'sis, THEODOR (1831-). A German historical and genre painter, born at Kaiserslautern. While studying law at the University of Munich, he took up painting at the Academy under Foltz and Wilhelm von Kaulbach, and after his return from a sojourn in Italy (1856-58), executed in the National Museum, at Munich, three mural paintings of episodes in the history of Charles X. and Charles XI. of Sweden (1859-61). Besides a series of cartoons to German folk songs and illustrations to Milton's *Paradise Lost*, a cycle of twelve paintings to Kinkel's epic poem *Otto der Schütz*, and a "Wagner Gallery" (1868-94), forty-five cartoons and paintings to Wagner's operas are among his most meritorious works. Subsequently he painted also portraits and especially charming scenes from child life. His easel pictures include "Huss at Constance Saying Farewell to His Friends" (1856, Bern Museum); "Calvin Visiting Servet in Prison" (1862); "The Thespian Chariot in a Scrape" (1873); "Arrival of Itinerant Actors" (1876); and "In Front of a Jeweler's Shop."

PIXLEY-FULFORD, ANNIE (1855-93). An American actress. She was born in New York, but she began her career as a singer in California. She was married to Robert Fulford in 1871 and made her debut on the dramatic stage in San Francisco in 1876. She appeared in New York in 1878. Her best-known part was that of M'Iss in the dramatization of Bret Hart's story. She died in London, November 8, 1893.

PIZARRO, pē-zār'rō, Sp. pron. pē-thār'rō, FRANCISCO (c.1470-1541). The conqueror of Peru. He was the illegitimate son of Gonzalo Pizarro, a prominent soldier in the army of the great captain Gonzalo de Córdoba, and was born at Trujillo, in Extremadura, Spain, where he

passed his boyhood earning his living as a swineherd. In 1509 he sailed for America with Ojeda, whose fortunes he followed for several years. In 1519 he settled down on a small land holding in the new city of Panama. Three years later he formed a partnership with Diego de Almagro (q.v.) and Father Luque to explore the country discovered by Andagoya to the south of the isthmus. A first expedition in 1524 accomplished nothing, and a second in 1526, undertaken with the assistance of Gaspar de Espinosa, threatened to ruin the partners. Enough of the country was seen, however, to prove that it contained much wealth, and so Pizarro landed on the island of Gallo, not very far from the equator, while Almagro returned for assistance. The sufferings of the men had been so great, however, that the Governor at Panama sent a vessel to bring them all back. Pizarro refused to embark, and drew on the sand with his sword the famous dividing line, beyond which he declared lay labor, hunger, thirst, sickness, and every kind of danger, but also the chance for glory and heroic achievement. Thirteen men crossed to stand by him, while the rest went back to Panama. Pizarro maintained himself for several months until the arrival of Almagro, and then they continued to explore the mainland as far as the Gulf of Guayaquil. Convinced that his resources were insufficient to embark upon the conquest of this highly civilized region, Pizarro collected irrefutable evidences of its wealth, and then went back to Panama, whence he proceeded to Spain in 1528. Charles V. granted him authority to conquer and govern this territory with the title of *Adelantado*. Pizarro enlisted a considerable force, including his four brothers. In 1530 he was back at Panama, and in January, 1531, he started for the real conquest of Peru. Landing at Tumbez, he learned of the weakened condition of the country, which the struggles between Atahualpa and Huascar, sons of the Inca Huayna Capac, had made an easy prey for a foreign conqueror. At Tumbez Pizarro was joined by Hernando de Soto. From this place Pizarro marched to Cajamarca, which was reached November 15, 1532. There Atahualpa came to meet him as a result of an exchange of friendly messages. Realizing his danger, surrounded as he was by many thousands of native warriors, Pizarro arranged that when Atahualpa had entered the great central inclosed courtyard of the village the Spaniards should suddenly attack the Peruvians from all sides. Atahualpa was secured as a prisoner (November 16, 1532), to be held as hostage for the safety of the force, scarcely a hundred strong. The native forces rapidly disintegrated, and Atahualpa, despite the ransom which he collected, estimated at \$17,500,000, was killed. A hundred and fifty fresh troops came from Panama with Almagro, and the country was rapidly reduced to subjection, except for scattered native bands which kept up the struggle for independence. Cuzco was occupied in November, 1533, and in January, 1535, Lima, the first of several towns founded by Pizarro, was formally organized. Meanwhile Hernando Pizarro, the eldest of the brothers, had gone to Spain with the royal fifth of Atahualpa's ransom. He returned in 1535 with various honors for the conquistadores, the title of Marquis for Francisco, and a grant of the Chilean region for Almagro. The conqueror devoted himself to the

development of the country, and was apparently succeeding quite as well as an administrator as he had done as a soldier, when the outbreak of the natives under Manco Inca (q.v.) in 1536 forced him to take up arms again. In the defense of Cuzco Juan Pizarro, perhaps the most brilliant fighter of the family, was killed. Almagro meanwhile returned from Chile, and as soon as the natives were driven off claimed Cuzco as lying within his territory. By a sudden attack he captured Hernando and Gonzalo Pizarro, and occupied Cuzco. After repeated negotiations and an interview which served only to add to the bitterness between the two former partners, the Marquis agreed to give up his claim to Cuzco on condition that his brother Hernando—Gonzalo having escaped—should be released. As soon as Hernando had arrived safely at his brother's camp Francisco declared war on Almagro. The latter, too old and infirm to mount a horse, directed his army from a litter. On the plain of Las Salinas, in April, 1538, the Pizarros completely defeated him. Almagro was caught and, his efforts to bribe his guards becoming known, ordered to be strangled or garroted, the recognized method of execution. The Marquis took up his headquarters in Cuzco and again began to develop the mining and other resources of the country. Hernando in 1540 returned to Spain to defend their actions, but the friends of Almagro had won the royal ear, and he was imprisoned, remaining for twenty years in nominal confinement at the Castle of Medina del Campo. The Marquis returned to Lima in 1540, and busied himself with administrative affairs. While at dinner, on Sunday, June 26, 1541, he was surprised by a band of conspirators under Juan de la Rada, who had united to champion the cause of Almagro's son and avenge the father's murder. Deserted by his guests, Pizarro defended himself until mortally wounded, made a cross with his blood on the floor and died as he kissed it. Prescott's *History of Peru* is principally an account of the career of Pizarro, and gives the standard version of the events of the conquest. It should be compared with Markham, *Peru* (Chicago, 1892), which embodies the results of later documentary studies.

PIZARRO, GONZALO (c.1505-48). A Spanish conquistador, brother of Francisco Pizarro. He was active in assisting his brother in the conquest of Peru, and after his escape from Almagro, who threatened to execute him (see preceding article), fought in Charcas, and in 1539 became Governor of Quito. He was sent in 1541 by the Marquis to investigate rumors of a land of cinnamon beyond the Andes. After a remarkable journey over the mountains the cinnamon trees were found, with no possible means of getting their product to a market. As the explorers were threatened with starvation, a boat was built in which Orellana (q.v.) started down the Napo River to seek food. Failing in this, Orellana deserted his chief, and became famous for making the first voyage down the Amazon. Pizarro eventually succeeded in getting back to Peru with a small remnant of his force. After the death of the Marquis Gonzalo remained in Peru to look after the interests of the family. When Blasco Nuñez Vela came from Spain with the title of Viceroy to assume the government of Peru and enforce the "new laws," doing away

with abuses in the treatment of the Indians, Gonzalo was persuaded to head a revolt against the Viceroy (1544). He occupied Cuzco, gathered a considerable army, and marched on Lima, capturing the city. The royal audiencia recognized Pizarro as Governor of Peru, and on October 28, 1544, he made a formal entry into Lima. The Viceroy returned from Panama, but was defeated at Anaquito, June 18, 1546, and all the royal party recognized Pizarro or left Peru. Gonzalo devoted himself to developing the mining regions, founding cities, and making large agricultural grants to settlers. In the spring of 1547 Pedro de la Gasca arrived with a powerful force to reestablish the royal power. Gonzalo, mustering his forces, marched against the royalists near Lake Titicaca, where he completely defeated them, October 26, 1547. Gasca soon collected his forces and marched on Cuzco. The armies met on the plain of Saesahuana, April, 1548, and as the battle was about to begin most of Gonzalo's best troops went over to the enemy. Realizing the situation, Pizarro followed surrendering himself. Gasca promptly called a council of war, which condemned Pizarro to death, and he was beheaded a few days afterwards.

PIZARRO. A melodrama by Sheridan, produced in 1799. It was taken from Kotzebue's drama *Die Spanier in Peru*, with some alterations, and became very popular on account of its patriotic sentiments.

PIZZICATO, pèt'sè-kä'tò (It., twitched), abbreviated *pizz.* A word used in music for stringed instruments to denote that the strings, instead of being played as usual by the bow, are to be twitched with the fingers in the manner of a harp or guitar. The letters *c. a.* (*col arco*, with the bow) indicate that the use of the bow is to be resumed.

PLACE, FRANCIS (1771-1854). An English reformer. He was apprenticed to a maker of leather breeches and himself worked at that trade and as a tailor. In 1794 he joined the London Corresponding Society, a reform club, and for three years was prominent in its work. After ten years of retirement (1797-1807) he returned to politics, made the acquaintance of William Godwin, Robert Owen, Jeremy Bentham, James Mill, and many others, and about 1812 began indirectly a great work, acting as tutor or coach to various Parliamentary reformers, among whom Joseph Hume should be mentioned. In 1824 he procured the abolition of the provisions against workingmen's combinations. Seven years afterwards he was interested in the Reform Bill, and by his placard, "Go for Gold and Stop the Duke," brought on a brief run on the Bank of England and contributed to the causes preventing Wellington's forming a Cabinet. With Roebuck he wrote various political pamphlets in 1835. Consult Wallas, *Life of Francis Place* (London, 1898).

PLACE, plàs, VICTOR (1822-75). A French Assyriologist and diplomat, born in Paris. He entered the Foreign Office in 1839, acted as consular agent in Naples, Gibraltar, and Haiti, showing himself able and brilliant, but grasping and self-seeking. In 1851 he became consul at Mosul, succeeding Botta, whose work of excavation at Khorsabad he continued in conjunction with Oppert and Fresnel. His discoveries, especially regarding Assyrian architecture, the large use made of

colored enameled bricks on the lower parts of city walls, and the variety and brilliance of borders and figure decorations on these mural facings, were very valuable. The actual spoils of the excavations were loaded on a float buoyed with bladders, but in spite of these precautions they were lost in the river near Basra and could not be recovered. Place was highly honored by the Academy of Inscriptions on his return to France in 1855, and became consul-general at Jassy in Moldavia, a post from which he was soon removed because of his abuse of power. He was sent to Adrianople in disgrace, but in 1870 was transferred to New York, where he took advantage of his office and his country's need, bought defective rifles for the French army, and charged so high a price for them that he made more than 600,000 francs for himself before he was discovered. He was twice tried in Paris, and was sentenced to ten years' imprisonment in 1872, but was pardoned by Thiers. Place's *Ninivé et l'Assyrie* (1867-70), text 2 vols., plates 1 vols.) is an authority on Nineveh.

PLACENTA (Lat., flat cake). The after-birth—a spongy vascular mass attached to the uterus before the birth of a young animal and expelled after labor is completed. It is the structure that unites the fetus to the wall of the maternal uterus. It occurs in all mammals except the egg-laying Ornithorhynchus and Echidna, though only rudimentary in the marsupials. It presents a variety of forms among the different mammals. Thus in the pig, mare, and the Cetacea it is diffused over the whole interior of the uterus and is termed *diffuse*; in ruminants it is attached in scattered segments over the uterine wall, *cotyledonary*; in certain of the Edentata, the elephant, and Carnivora it occurs as a zone around the uterine surface, *zonary*; in most of the Edentata, the Insectivora, and Rodentia it is found as a circular disk, *discoidal*; while in the monkeys and man, being first arranged in scattered patches and later as a disk, it is known as *meta-discoidal*. The placenta is formed in its greater part from hypertrophy and other changes in those chorionic villi which chance to be in contact with the uterine surface when fetation begins. The development of these adherent villi produces what is known as the fetal portion of the placenta, while the decidua serotina (see FŒTUS) furnishes the maternal portion. Around the placental villi are developed vascular spaces in which certain arteries and veins from the uterine wall communicate freely. The villi being thus immersed in the maternal blood, osmotic interchange takes place between the fetal and maternal circulations. On gross inspection the placenta presents itself as a round or slightly oval disk from six to eight inches in diameter and from three-quarters to an inch in thickness. Its weight is about a pound. The fetal surface is smooth and covered by the amniotic membrane, which is reflected from the cord on to the placenta at its centre and again from the placental margins to the uterine wall. The maternal surface is deep red, rough, and irregular, and divided by numerous grooves or sulci. A close inspection shows this surface to be covered by a fine delicate membrane which dips down into the sulci and which is the stripped-off cellular layer of the decidua serotina. Attached to the fetal surface of the placenta, usually at its centre, but occasionally

at or near its margin, is the umbilical cord. The cord is a whitish semi-transparent structure of an average length of about twenty inches and a diameter about that of the little finger. It consists of two arteries and a vein twisted upon one another and surrounded by a peculiar substance called from its consistence the jelly of Wharton, which gives the cord its characteristic appearance.

The function of the placenta is both respiratory and alimentary. It aerates the fetal blood by gaseous interchange of oxygen for carbon dioxide and other gaseous waste products. (See CIRCULATION; and BLOOD.) In its nutritional function it supplies material for the rapid growth of the fetus, at the same time removing the products of tissue decomposition. The placenta is subject to several pathological abnormalities in form and attachment, to inflammation, and to degenerative changes. For their detailed description, and for the treatment of that dangerous form of misplacement known as placenta previa, consult: Jewett, *The Practice of Obstetrics* (New York, 1900); *American Systems of Gynecology and Obstetrics* (ib., 1899).

PLACENTA. In plants, the region to which ovules are attached in a plant ovary. It sometimes appears as a mere thickening of the walls, or as a more decided projection from the walls—parietal; sometimes several are united in a central column—axial. These distinctions are important distinguishing characters of certain natural orders. The number of placenta corresponds with double the number of carpels, each carpel normally producing two rows of ovules.

PLACENTIA. The ancient name for Piacenza (q.v.).

PLACE OF WAILING. An inclosed place near the Mosque of Omar in Jerusalem, where the Jews congregate on Friday to lament the fall of Israel and pray for its restoration. The wall at which they gather is believed to be the only remaining part of Solomon's temple.

PLACETAS, plā-sā'tās. A town of the Province of Santa Clara, Cuba, 22 miles southeast of the city of Santa Clara, and connected by rail with the coast towns of Caibarien and Sagua la Grande (Map: Cuba, F 4). It is in the midst of an extensive sugar-producing region. Its population in 1899 was 5409.

PLACIDE, plā-sēd', HENRY (1799-1870). A noted American comedian, born in Charleston, S. C., September 8, 1799. He was the son of a French dancer, and his training for the stage began in childhood. After several years in the South he made his appearance in 1823 at the Park Theatre, New York, as Zeckel Homespun, one of his most popular characters, and for the next twenty years he was a member of the Park Theatre company. Here and afterwards as a star he seems to have won the unmingled admiration of the critics in rôles as varied as those of the fat boy in *Pickwick*, Sir Harcourt Courtly in *London Assurance*, Sir Peter Teazle, Dr. Ollapod, and Grandfather Whitehead. After his retirement in 1865 he settled in Babylon, L. I. where he died, January 23, 1870. Consult: Ireland, *Records of the New York Stage* (New York, 1866-67); Keese, *A Group of Comedians* (ib., 1901).

PLACID'IA. See HONORIUS, and VALENTINIANUS III.

PLACODERM (from Gk. πλάξ, *plax*, tablet, plate + δέρμα, *derma*, skin). An order under the subclass Ganoidei in the older classifications of fossil fish. It included genera in which the head and forward part of the trunk were covered by heavy plates; for example, *Pterichthys*, *Bothriolepis*, *Coccosteus*, *Dinichthys*. The group was based on superficial resemblances, and it has been broken up and the genera distributed among other orders. See OSTRACODERMI; LUNGFISH; ΔΙΠΝΟΙ; and articles on the genera mentioned above.

PLACOIDEI, plā-koi'dé-i (Neo-Lat. nom. pl., from Gk. πλακώδης, *plakōdēs*, flat, from πλάξ, *plax*, tablet, plate + εἶδος, *eidos*, form), or **PLACOID FISHES.** An order of cartilaginous fishes, in the classification proposed by L. Agassiz, characterized by having 'placoid' scales, irregular plates of hard bone, not imbricated, but placed near together in the skin. These scales or plates are of considerable size in some fishes, but in others they are very small tubercles, as in the dogfish, of which the skin forms fine-grained shagreen. The term is no longer in scientific use.

PLACOPHORA (Neo-Lat. nom. pl., from Gk. πλάξ, *plax*, plate, tablet + φέρειν, *pherein*, to bear). A division of Mollusca, containing only the chitons. The modern chitons are descendants of a race which, though never represented by any considerable number of species or individuals, began in the early Paleozoic and persisted with little change of form down to the present day. The first are known in the Ordovician rocks, they are scattered through the Silurian and Devonian, and they attained a slight prominence in the Carboniferous. The Paleozoic species number about 20, and they are distinguished from those of the Mesozoic and Tertiary by the less perfect articulation of their valves and lesser degree of ornamentation of the surfaces of their shells. Few Mesozoic species are known and the group is represented in the Tertiary by about 50 species that show very close relationship to the modern forms.

PLA'GIARY, Sir FRETFUL. A vain and irritable character in Sheridan's play *The Critic*, intended to ridicule Richard Cumberland, the dramatist.

PLAGIAULAX. A genus of Jurassic mammals, typical of the family (Plagiaulacidæ), known only from lower jaws fossilized in the English Purbeck beds, which imply an animal of the size of a small rat and representing the primitive multituberculate type of dentition. (See illustration.) It is believed the rodent-like incisor teeth did not grow from persistent pulps, and they have no anterior coating of enamel. The centre of the two molars on each side is hollowed, and the raised rim is biset with tubercles. Associated genera are *Bolodon*, *Allodon*, and *Ctenacodon*, the last named based on lower jaws found in the Laramie formation of Wyoming.

PLAGIAULAX MINOR.
Right lower jaw, showing molars (m) and premolars (p).

Woodward says that the family does not seem to have become extinct until early Tertiary times, for two other genera, *Neo-plagiulax* and *Ptilodus*, are known from the lower Eocene of France and New Mexico respectively.

PLA'GIOCLASE (from Gk. *πλάγιος*, *plagios*, oblique + *κλάσις*, *klasis*, fracture, from *κλάν*, *klan*, to break). A name originally introduced by Breithaupt and applied by him to the triclinic feldspars of the albite-anorthite series of minerals contained in the feldspar group. See **FELDSPAR**.

PLAGIOSTOMI, plāj'ī-ōs'tō-mī (Neo-Lat. nom. pl., from Gk. *πλάγιος*, *plagios*, oblique + *στόμα*, *stoma*, mouth). A suborder of cartilaginous fishes, including the sharks and rays. See **ELASMOBRANCHII**.

PLAGUE (Lat. *plaga*, plague, destruction, injury, blow, from *plangere*, connected with Gk. *πλήσσειν*, *plēssein*, Lith. *plakti*, to strike, and possibly with Goth. *flōkan*, OHG. *fluohhōn*, Ger. *fluchen*, to curse), **PESTIS**; **PESTIS BUBONICA**; **PESTIS INGUINALIS**; **BUBONIC PLAGUE**; **BLACK DEATH**. An acute infectious disease caused by the presence of a specific microbe and characterized by the enlargement and suppuration of lymphatic glands.

HISTORY. Under **BLACK DEATH** is given the history of plague to and including the pandemic of 1334 to 1351, when China, India, Persia, Russia, Germany, Italy, France, England, and Norway were devastated, and many millions of deaths resulted. Proust is authority for the statement that between the eleventh and fifteenth centuries at least thirty minor epidemics of the disease appeared in different parts of Europe. A grave and important epidemic was traced from Syria to Marseilles in 1720, when 86,000 people fell victims to the plague in that city. During the epidemic of 1770-71, which probably passed from Jassy through Kiev, 80,000 persons lay dead of the scourge in Moscow alone. Early in the nineteenth century Constantinople became the seat of two severe epidemics, one in 1803, with 150,000 deaths, and the other in 1813, with 110,000 deaths. The Balkan peninsula was visited by the dread disease on several occasions between 1814 and 1841; Greece suffered in 1828, and the southern part of Italy in 1815. Russia, in the neighborhood of Astrakhan, was swept by an epidemic from 1877 to 1879. While Europe was passing through this history and finally emerged from the shadow of the plague in 1879, Africa and Asia were suffering terribly. Kitasato reports 21 epidemics between 1783 and 1844 in Egypt. Tripoli suffered in 1874, as did also Arabia. In the river valleys of the Tigris and Euphrates outbreaks of plague occurred in 1773, and several subsequently and as lately as 1876, from which date it raged until 1895. The plague in Persia has been intermittent and of frequent occurrence; perhaps the epidemic of 1876-77 is most noteworthy, because it was the source of the Russian infection in 1877. In India the disease has been endemic for centuries, although reliable and accurate accounts date only from 1815. Its record since that date has been unbroken. Bombay has been a special sufferer since 1896. To trace or chronicle the course and outbreaks of the plague in China is very difficult. The greatest visitation of the scourge, in 1342 and the following years, has been

described. (See **BLACK DEATH**.) There were outbreaks of the disease in 1850, 1866, 1871 and 1872, and subsequently. The pandemic of 1894 continues. It has been learned since Japan annexed Formosa that plague has existed in the latter country for a very long time.

CAUSE. Plague is not caused by filth, overcrowding, diseased grain, or inundations. It is always caused by the presence of the plague bacillus, or *Bacillus pestis*. The microorganism was discovered independently by Kitasato and Yersin in 1894. It is a small oval rod, short and thick, with rounded ends that take stain more readily than the central portion, showing the 'pole staining.' The bacilli are found in pairs or singly, and, in cultures, arranged in chains. They do not form spores and are motile. They occur in enormous numbers in the smaller glands (buboes), in the spleen, and after death in the blood. The lower animals, especially rats, are infected in large numbers from the dust in pest-laden houses. The unsanitary conditions under which the affected individuals live give ample opportunity for the direct or indirect transmission of the disease from patient to patient. Flies and other insects carry it. (See **INSECTS, PROPAGATION OF DISEASES BY**.) Kitasato considers that the bacillus may enter the body by the skin surface, through cracks or wounds, by the respiratory passages, or by the alimentary canal.

SYMPTOMATOLOGY. Two forms of the dread disease are described—*pestis major* and *pestis minor*. *Pestis minor* includes various pathological conditions, all of favorable prognosis, presumed to be caused by the plague infections. Slight fever, slight swelling of the glands, or local tenderness with trivial systemic involvement, constitute the attack. In other cases, prostration, headache, vertigo, and gastro-intestinal disturbances occur. Those cases occurring in houses in which plague has been found, and during a plague epidemic, are considered to be related to the scourge; but no bacteriological examinations have verified the suspicions. *Pestis major* (the severe or ordinary plague) may be of one of the following five varieties: (1) Bubonic, (2) pneumonic, (3) septicæmic, (4) pyæmic, or (5) local inoculation. An average attack of ordinary bubonic plague presents the following course: The period of inoculation lasts from three to seven days. The period of invasion, or prodromal period, varies from 24 to 48 hours in length, and during it the patient suffers with chills, fever, weakness, lassitude, vertigo, headache, and vomiting. Bubo development follows, with staggering gait, tremulous speech, and great restlessness; a temperature of 104° F. or higher; a full pulse, averaging 130 to the minute; a dry granular tongue covered with a yellow velvety fur, but with a red margin; an anxious and pallid face; constipation; and the enlargement of glands in the neck, groins, or axilla, constituting the buboes. Following the appearance of the buboes occurs a fall in temperature and pulse rate, and this generally on the second or third day of the disease. After a remission of a little over two days, the fever ascends to 103° or 105° F., at which point it remains for seven days, during which time the bubo reaches its full development. After 10 days the temperature falls. Emaciation and exhaustion are extreme. The patient may now die of heart failure, in syncope; or of

hemorrhage, of peritonitis, of jaundice, of hyperpyrexia; or he may recover after about two months' convalescence. The buboes often suppurate, or become necrotic, sometimes involving considerable areas of surrounding tissues. Sometimes foci of broncho-pneumonia are found in the lungs, each focus surrounded by a congested pulmonary tissue. Occasionally the alveoli are found full of sanguinolent fluid which is swarming with plague bacilli. Or, multiple abscesses and pulmonary infarcts are noted. These cases in which lung involvement is prominent are called pneumonic plague.

PROGNOSIS, MORBIDITY, AND MORTALITY. In the vast majority of cases the prognosis of the disease is extremely unfavorable, much depending on the character of different epidemics. Septicæmic and pneumonic cases are almost always fatal. After convalescence, weakness and a neurasthenia may persist for a long period. The rate of mortality varies much. In certain epidemics from one-half to three-quarters of an entire population has perished. In the Hong Kong epidemic of 1894 the mortality was 95 per cent. In Bombay during 1896 and 1897 it was 50 to 60 per cent., while during 1898 to 1901 it averaged 80 per cent.

PROPHYLAXIS. As the eliminated bacilli may enter the healthy individual directly by cutaneous infection, by inhalation, or by ingestion (as has been abundantly proved), or may enter indirectly, by means of flies, fleas, rats, etc., it is evident that inspection, isolation, and disinfection must be employed to prevent or limit an epidemic of plague. Among the preventive methods are general hygiene, good drainage, clean water-supply, cleanliness in dwelling houses, and cleanliness of streets. Isolation of the sick must be early employed, and infected dwellings must be thoroughly disinfected, as also wearing apparel, bed linen, etc. Formaldehyde gas is probably the most thorough and convenient disinfectant. Chloride of lime is recommended for disinfecting feces, as well as for covering dead bodies of human beings, as well as of all animals dying during an epidemic. Isolation of the convalescent must be continued, according to Kitasato, for a month after apparent recovery; for the plague bacilli are found in the blood for a period varying from three to four weeks after the cessation of all symptoms of the disease. Rigid quarantine may be necessary during an epidemic.

Specific prophylaxis may be employed before or during an invasion of the dread disease by means of 'Yersin's antipest serum' or 'Haffkine's prophylactic fluid.' The serum devised by Yersin is blood serum taken from horses that have been inoculated with the plague. Hypodermic injection of the serum causes immediate immunity, which unfortunately lasts only 12 to 14 days. A difficulty in securing acquiescence in repeated injections at once arises, and as a popular treatment it is under a disadvantage. Haffkine's fluid is a culture of the *Bacillus pestis* rendered virulent by special methods, the bacilli, after abundant growth, being killed by an exposure to a temperature of 70° C. for several hours. Inoculation with Haffkine's fluid has the advantage of conferring immunity lasting from a few days to several months. Calmette, director of the Pasteur Institute at Lille, France, states that a single inoculation of three cubic centi-

eters of Haffkine's fluid a month old establishes immunity only after the seventh day and for a variable period thereafter. A great disadvantage in the use of the prophylactic fluid lies in the facts that during immunization the person is more susceptible to plague; and that if he already had contracted even a mild attack, the inoculation would be fatal. Authorities recommend the provision of antipest serum for prompt use in order to arrest an epidemic in the first cases, and the employment of Haffkine's fluid to inoculate the people dwelling in localities threatened with an invasion of the disease.

TREATMENT. The treatment of plague has been in the past mainly symptomatic. Early administration of calomel, followed by antipyretics, tepid sponging, alcoholic stimulants, ether, camphor, ammonia, and digitalis have all been of benefit in mild cases. Incision of the bubo and excision of suppurating and sloughing glands have been practiced. But the best results have been obtained from the use of Yersin's serum. It has increased recoveries 15 per cent., besides being an unquestioned preventive. In Belgium, India, in 1900-01, where a systematic test of the prophylactic was made, 61.4 per cent, was the mortality. In the fall of 1899, Lord Curzon, Viceroy of India, who gave personal attention to the plague hospitals and segregation camps, enthusiastically advocated inoculation with Haffkine's fluid, and set an example by having himself and his party inoculated, which was of great value in preventing panic and in encouraging proper measures for protection.

RECENT SPREAD OF THE PLAGUE. The scourge reached England in 1899, in the person of a sailor from Calcutta, who was landed at Plymouth. To the same port a coal-trimmer from Bombay was brought, suffering from plague. In England, in 1900, there were four cases, with two deaths; in 1901 there were 14 cases and 11 deaths. Eleven cases were reported in Glasgow in 1900, with one death. New York City was reached by the plague in November, 1899, on a coffee steamer from Santos, Brazil, aboard of which two men were sick with plague on reaching quarantine. There was no spread of the disease. In December, 1899, the fell disease appeared in Honolulu, Hawaiian Islands, probably brought from Japan. There were four cases and two deaths. In 1900 the islands reported 84 cases, with 64 deaths; in 1901, 13 fatal cases. In 1900, of two cases reaching the port of New York, one proved fatal in quarantine; in 1901 a stoker on a steamer from Calcutta appeared at quarantine as a case of plague. Undoubted bubonic plague was uncovered in November, 1900, in the Chinese quarter of San Francisco, and a large area was declared infected. Great difficulty was experienced by a special commission which explored this quarter, and which finally reported in 1901 that there had been in all 42 fatal cases of the plague in San Francisco. Manila, P. I., furnished a few cases of plague in 1899, and in 1900 there were 399 cases, with 281 deaths, reported from the Philippines; while in 1901 the figures reported were 497 cases, with 375 deaths.

The United States Marine Hospital Service prepares at its hygienic laboratory a quantity of the prophylactic fluid of Haffkine, for distribution to national, State, and local quarantine officers throughout this country. The Pasteur In-

stitutes at Lisbon and at Paris distribute anti-plague serum to different parts of Europe.

PLAGUE, CATTLE. A disease of cattle. See **TEXAS FEVER.**

PLAGUE YEAR, JOURNAL OF THE. An imaginary narrative by Daniel Defoe (1722) of the plague of London in 1665, so vivid and realistic that it has often been taken as actual history.

PLAGUES OF EGYPT. A series of miraculous signs and judgments by which, according to Exodus vii. 8-xi. 10; xii. 29-xiv. 26-29, Moses and Aaron proved that they were messengers of Yahweh, Israel's God, and punished the people of Egypt for the King's obstinate refusal to let the Israelites go into the wilderness to celebrate a festival. Ordinarily the plagues are regarded as 10 in number, viz.: (1) The turning of the river into blood, (2) frogs, (3) lice, (4) flies, (5) murrain, (6) boils, (7) hail, (8) locusts, (9) darkness, (10) the slaying of the first-born. It is evident, however, that the author of Exodus iv. 9 looked upon the turning of water into blood as the third sign, two others having preceded, the change of a rod into a serpent and the serpent into a rod again, and the hand turning leprous and being restored. All scholars are agreed that the narration is composite. Although the original Yahwistic and Elohist (see **ELOHIST AND YAHWIST**) narratives have not been preserved intact in the priestly redaction (see **HEXATEUCH**), it is possible to discern the general characteristics of each. The Yahwist made Moses merely the proclaimer of each sign, which then was wrought by Yahweh himself, while the Elohist made Moses stretch forth his hand and bring the evil upon Egypt. The Yahwist seems to have told of seven plagues, viz. the waters smitten, the frogs, the flies, the murrain, the hail, the locusts, and the death of the first-born. Of the Elohist plagues only the turning of the water into blood, the hail, the locusts, the darkness, and the death of the first-born seem to have been retained, though it is possible that this document also contained another pentad, viz. the rod and the serpent, the leprous hand, the frogs, the lice, and the boils. It is generally recognized that the flies and the lice are the same plague, and also that the murrain and the boils are only variants. The priestly editor naturally introduced Aaron and his rod, and otherwise combined and retouched the narration so as to emphasize the contrast between the Egyptian magicians and the chosen representatives of Israel's God. It is to be noticed that the Yahwistic story, which is probably of Judean origin, has least of a distinctive Egyptian setting, while the Ephraimitish author of the Elohist narrative here as elsewhere reveals more familiarity with Egypt. The priestly redaction, which dates from the Persian period, reflects a crystallized tradition as to Israel's deliverance from Egypt and the triumphant conflict with heathen idolatry and magic. The attempt to save the number 10 probably found in the Elohist may account for the separation of the rod and serpent sign and the awkward fact that the threatened sign of the leprous hand is not carried out. The increasing evidence that there was a State in North-western Arabia called by the Assyrians Muzri has led some critics and historians to the view that the scene of these plagues was originally laid not in Egypt, but in this Arabian Muzri,

south of Syria. It seems to be in harmony with the view that the Judean story, supposed to be the earliest, presents a series of calamities that may befall any country. There is no natural succession depending on the local phenomena of Egypt. The miraculous element is indeed present, all such evils being regarded as direct blows struck by an angry deity. But the memory of some extraordinary sufferings of the people in Muzri connected with or causing the departure of Moses' clan may well have been the historic nucleus of the story. Canon Cheyne thinks of the sacrifice of the first-born by the Muzrites as the occasion of the migration of those who preferred to redeem their first-born. If this were so, the demand to go away to celebrate the leap-feast, at which the firstlings of the animals but not men were offered, would possibly be a part of the original tradition. But the story of Jephthah's offering (see **FESTIVALS**; **JEPHTHAH**) seems to show that the substitution of redemption for actual sacrifice was introduced at a later time. It has been maintained that especially the so-called priestly writer bases his plagues throughout upon the order in which such occurrences would naturally come in Egypt in the course of the year. It is extremely doubtful, however, whether the story in any form connected the change of the water into blood with the discoloring of the Nile water as it rises at the end of June. This was not a calamity, but the earnest of great blessings. The heaping up of dead frogs would naturally cause various plagues. But it is evident that to these authors each plague is a fresh miracle. Consult: Dillmann, *Exodus and Leviticus* (Leipzig, 1880); Holzinger, *Exodus* (Tübingen, 1900); Baentsch, *Exodus-Leviticus* (Göttingen, 1900); Macalister in the *Hastings Dictionary of the Bible*, vol. iii. (New York, 1900); Cheyne in *Encyclopædia Biblica*, vol. iii. (London, 1902).

PLAICE (OF. *plais*, Fr. *plaise*, Sp. *platiya*, from Lat. *platessa*, flatfish, plaice, from Gk. *πλάρῆς*, *platys*, flat. Lith. *platus*, broad, Skt. *prthi*, wide, from *prath*, to spread out). (1) A European flounder (*Pleuronectes platessa*) rather broad in proportion to its length; the upper surface of the body and the fins olive-brown, marked with large bright orange spots; a row of similar spots on the dorsal fin and on the anal fin. The plaice inhabits sandy and muddy banks, not in very deep water, feeds on worms, mollusks, small crustaceans, and young fishes, and ordinarily weighs seven or eight pounds. It is taken both by lines and trawl nets, and its flesh is highly esteemed. (2) In America the name is locally applied to the summer flounder (*Paralichthys dentatus*; see **FLOUNDER**), an extensive account of which is given in Goode, *Fishery Industries*, sec. i. (Washington, 1884). See Plate of **FLAT-FISH AND FLOWNERS**.

PLAIDEURS, plá'dēr', LES. The only comedy of Racine (1668). It was suggested by the *Wasps* of Aristophanes, and ridicules the customs and abuses of the French legal profession. Its three acts abound in amusing situation and sparkle with wit.

PLAIN (OF. *plain*, from Lat. *planum*, level ground, plain, neu. sg. of *planus*, level, even; connected with Lith. *plónas*, flat, OPruss. *plonis*, threshing-floor, OLat. *palma*, Gk. *πλάμη*, *plamé*, flat of the hand, *πλαξ*, *plax*, plain, *πλανᾶν*, *planan*,

to wander, OHG. *flah*, Ger. *flach*, flat. OHG. *rluor*, Ger. *Flur*, AS. *flōr*, Eng. *floor*, OIr. *lār*, floor). An expanse of level or gently sloping land. In contrast with a plateau, the surface of a plain is disposed at a low elevation, generally less than 1000 feet, although no sharp line of division can be drawn between the two. The Great Plains of the United States have an elevation on the western border of 2000 feet or more. In respect to their origin, plains may be classed as marine, lacustrine, fluvial, and plains of denudation. *Marine plains* are formed by the deposition of sediment beneath the sea. The debris brought down by rivers to their mouths is carried seaward by tides and currents and distributed over a wide area. Thus in time a broad belt of sedimentary strata accumulates along the margins of continental lands, and these sediments may subsequently be raised into land. The Coastal Plain (q.v.) which extends along the Atlantic and Gulf borders of the United States and the North German Plain have been formed in this manner. The marine origin may be demonstrated by the character of the fossils included in the strata. *Lacustrine plains* occupy the basins of former lakes whose disappearance may have been brought about in various ways. The celebrated Vale of Kashmir in Northwestern India and the great Hungarian Plain are covered with fine sediments that were deposited in bodies of fresh water before the outlets had been cut down. In Nevada and Utah there are extensive lacustrine plains which have been laid bare owing to a change of climate from moist to arid conditions, and similar plains are known to occur in Central Asia. A peculiar type is that illustrated by the valley of the Red River of the North; during the Glacial period a great lake was formed here only to disappear with the retreat of the obstructing ice-sheet. (See LAKE, LAKE AGASSIZ.) *Fluvial plains* are built up by the deposition of silt along the borders and at the mouths of rivers. The Mississippi, the Nile, the Ganges, and most of the large rivers of the world have constructed extensive fluvial plains. (See FLOOD-PLAIN; DELTA.) *Plains of denudation* owe their origin to erosion. When land has acquired considerable elevation above the sea the surface is dissected by the action of running streams which are constantly engaged in widening and deepening their channels. This process when carried to completion results in the reduction of the divides between the streams, producing a broad lowland whose surface lies but little above sea level. If the former elevations are still indicated by unconsumed hills the lowland is called a peneplain. The plain thus produced may again be elevated and once more subjected to the process of dissection and base-leveling. The great plain of Central Russia and the lowlands bordering the Appalachians have probably been formed in this way. See GEOGRAPHY; PHYSIOGRAPHY.

PLAIN, THE. In the history of the French Revolution, the moderate party in the Legislative Assembly and Convention, so called in contradistinction from the Mountain (see MONTAGNARDS).

PLAIN CHANT. A term applied to the ecclesiastical chant of the Roman Catholic Church. This style of music was used in the Church from the earliest times. It has certain characteristics which distinguish it from any other known music.

All the melodies have a stateliness and quiet dignity rendering them particularly appropriate for the use of the Church. The tempo is moderate, and each melody is written in one of those tonalities known as the Church modes. (See MODES.) For the notation a staff of four lines is used, and the notes are all black and square or lozenge-shaped. For the history and development of this system of plain chant notation, see MENSURABLE MUSIC and MUSICAL NOTATION.

The origin of plain chant has been the subject of much speculation, but the best authorities now agree that it seems exceedingly probable that the chants of the early Christian Church were either taken directly from or modeled after those of the Hebrews. This supposition is borne out by the information we possess regarding the performance of the music during the first three centuries of the Christian Era; for the singing was antiphonal, i.e. a precentor intoned the melody and the chorus answered. We have the testimony of Philo, a Hebrew writer of the first century, that the psalms in the Christian Church were rendered by a double chorus singing in alternation. It does not seem probable that these old psalms should have been sung to any other music than the old tunes. This music is scarcely more than emphatic declamation moving within the compass of a fifth; only the cadences present a little more melodic variety. The use of instruments was strictly forbidden, because these played an important part in the religious cult of the pagans. This prejudice against instruments lasted for centuries. Plain chant, the only form of music ever officially sanctioned by the Church, never made use of instruments. Even the complicated polyphonic works of the school of the Netherlands and the great Roman school banish instrumental accompaniment. It is only with the rise of the school of Venice toward the end of the sixteenth century that instruments find their way into the Church. When the plain chant melodies arose harmony was utterly unknown, and, consequently, the whole theory of music turned about melodic progression. Choral singing meant nothing else than singing in unison. As long as the persecutions compelled the early adherents of the faith to worship secretly in the catacombs, it was impossible to establish a universal liturgy. However, the melodies were preserved among the various congregations and handed down from generation to generation by oral tradition, though we can scarcely doubt that in the course of time the original melodies became more or less distorted. When, after the conversion of Constantine in 312, Christianity became the State religion, free intercourse between the different congregations became possible. Choirs were formed and received special training, so that congregational singing disappeared more and more. At the Council of Laodicea in 367 a decree was passed prohibiting any one but the regularly trained singers from singing in church. In the beginning of the fourth century Pope Sylvester established a singing-school at Rome, which resulted toward the end of the same century in the composition of original hymns. Some of the oldest of these hymns are attributed to Saint Hilary, who was Bishop of Poitiers about 335. Saint Ambrose, Bishop of Milan, who died in 397, devoted all his energies to the arrangement and systematizing of all the then known plain chant melodies. To him is also ascribed the introduction of the

four authentic modes, which he selected from among the seven octave species of Ptolemy, because these four most closely resembled the character of the ancient psalm-tones. Although the four authentic modes correspond to the Greek Phrygian, Dorian, Hypo-Lydian, and Hypo-Phrygian modes, the Greek names were discarded and the appellations *protos*, *deuteros*, *tritos*, and *tetartos* substituted. Saint Ambrose also composed a great number of original hymns, such as: *Deus, creator omnium*; *Æterne rerum conditor*; *Veni, redemptor gentium*; *Jam surgit hora tertia*. See AMBROSIAN CHANT.

After the death of Saint Ambrose the original purity of plain chant melodies was corrupted. When in 590 Gregory I. became Pope, church music was in a deplorable state. Recognizing the fact that music is one of the greatest aids to religion, Gregory began his reforms by establishing the *Schola Cantorum*, which in a very short time rose to an institution of the highest importance and for centuries preserved the ancient traditions. Since the time of Saint Ambrose a large number of new hymns had been composed. The old monotony of the chants had given place to a more varied melody, and this naturally led to an extension of the compass beyond the original fifth. The four original or authentic modes were no longer sufficient. Gregory is credited with having established the four *psalmodies* to meet the demands of the advanced art. Besides, he also selected the chants that were to be sung on every day throughout the Church year. The texts and melodies he ordered to be written in a book called *Antiphonarium*, which was declared to be the absolute authority in matters of church music. The system of notation employed in this book is that known as Neumes (q.v.), consisting of various signs placed above the syllables without employment of a staff. After plain chant had thus been reformed it spread with astonishing rapidity over all Europe. Especially Charlemagne was instrumental in promulgating this *Cantus Romanus*; for at diets held at Aix-la-Chapelle in 803 and Diedenhofen in 805 he issued strict orders to introduce this manner of singing in all the dioceses of his empire, and established singing-schools in various cities, as Soissons, Toul, Orleans, Cambrai, Lyons, and Dijon. Even before the accession of Charlemagne singing-schools had been founded at Fulda and Saint Gall, but as new hymns were constantly being written, the purity of the style was almost certain to suffer. Thus in 1323 Pope John XXII. was obliged to issue a bull restraining musicians from unlawful innovations. Acting upon the recommendation of the Council of Trent, Pope Gregory XIII. in 1576 took active steps towards a purification of the style of church music. But by that time the art of music had made enormous strides; polyphonic music had arisen. Although the new music had never been officially sanctioned, it was not only tolerated, but was favored. Composers were in the habit of taking the old plain chant melodies as a *cantus firmus* for the tenor, against which the other voices were set contrapuntally. Many composers had little scruple in distorting the original melodies to suit their purpose. But a greater danger to church music arose from the fact that it became customary to substitute popular secular melodies for the plain chant. At this time Palestrina established the true polyphonic

church style. This is founded upon the church modes; simplicity and noble dignity are its fundamental principles, as they ever have been the principles of plain chant. Since the time of Palestrina no new melodies have been added to the large stock of plain chant. Composers have devoted their talents to polyphonic music, but the old plain chant melodies have remained in constant use up to the present day. The custom at High Mass is to sing the *Kyrie*, *Gloria*, *Credo*, *Sanctus*, and *Agnus Dei* in polyphonic or modern harmonic style with instrumental accompaniment. The Introit, Gradual, Tract (or Sequence), Offertory, and Communion, if sung by the choir, are sung in unison to the old plain chant melodies, to which the organ supplies the harmonies strictly in accordance with the rules governing the church modes. The *Sursum corda*, Preface, and *Pater noster* are set to the ancient unvarying melodies. The advance of musical archaeology during the past century has done much toward the restoration of the plain chant melodies to their original purity. Pope Pius IX. ordered the Sacred Congregation of Rites to revise and publish, with the sanction of the Holy See, the entire treasure of plain chant melodies. The first volume appeared in Ratisbon in 1871, and within ten years the work of revision was completed.

The discovery and study of old manuscripts during the last half of the nineteenth century has brought to light many facts formerly not known. Some scholars cast doubt upon the work commonly ascribed to Gregory I. But the old tradition was not seriously shaken until the learned F. A. Gevaert in 1890 published his book, *Les origines du chant liturgique de l'église latine*, in which he attacks with weighty arguments the position ascribed to Gregory in the development of plain chant. But this was only the precursor of another book, *La mélodie antique dans le chant de l'église latine*, which appeared in 1895. The first work had raised a host of opponents who were unwilling to surrender a thousand-year-old tradition. In the second book, a work of stupendous learning, Gevaert meets all objections with proofs drawn from various ancient manuscripts and even strengthens his original statements. The important points brought out by the investigation of Gevaert are as follows: (1) The claims made by the adherents of tradition in favor of Gregory cannot be established on any historical grounds. (2) It is a legend that originated during the reign of Charlemagne or slightly earlier. (3) It was not generally accepted until the eleventh century. (4) The work of the compilation and composition of the chants of the Liturgy was in reality the work of the Greek popes that occupied the Papal chair at the end of the seventh and the beginning of the eighth century. (5) The melodies of the *Antiphonale Missarum* received their final form between the accession of Leo II. (682) and that of Gregory II. (715). The Pope that was particularly active in this work was Sergius I. (687-701). (6) The *Antiphonale Officii* had received its final shape during the pontificate of Agatho (678-681). Each of these points Gevaert establishes on the strength of ancient documents of unquestioned authenticity.

For a technical exposition of the nature and history of plain chant, consult Gevaert's learned work already cited, *La mélodie antique dans le chant de l'église latine* (Ghent, 1895). Other works are: Haberl, *Magister Choralis* (Rat-

isbon, 1896); P. Wagner, *Einführung in die gregorianischen Melodien* (Freiburg, 1895); Briggs, *History and Characteristics of Plain Song* (London, 1891); Lootens, *La théorie musicale du chant grégorien* (Paris, 1895); Bonuzzi, *Metodo teoretico-pratico di canto gregoriano* (Solesmes, 1894); Pothier, *Les mélodies grégoriennes* (Tournay, 1880); Dickinson, *Music in the History of the Western Church* (New York, 1902).

PLAIN DEALER, THE. A comedy by William Wycherley, produced in 1674, printed in 1677. The plan was taken from Moliere's *Le Misanthrope*, but the tone of this repulsive story is quite different. The principal characters are the sea-captain, Manly, the Plain Dealer, the crafty and odious Olivia, and the comic Widow Black-aere and her son.

PLAINFIELD. A town including several villages, in Windham County, Conn., 16 miles northeast of Norwich; on the Quinebaug and Moosup rivers, and on the New York, New Haven and Hartford Railroad (Map: Connecticut, H 3). It has public libraries at Moosup and Plainfield villages, and in Plainfield village is the old Plainfield Academy, which was one of the best known in New England toward the close of the eighteenth century. The chief industrial establishments include cotton and woolen mills, thread and yarn factories, a foundry, and wagon shops. The government is administered by town meetings. Plainfield, originally called Quinebeag, was settled about 1691 and was organized as a town in 1699. Population, in 1890, 4582; in 1900, 4821.

PLAINFIELD. A city in Union County, N. J., 24 miles west by south of New York City, of which it is a residential suburb; on the Central Railroad of New Jersey (Map: New Jersey, D 2). It is picturesquely situated at the base of the steep wooded ridge known as First Mountain, is well laid out, and has public parks, the Muhlenberg Hospital, and a public library with more than 20,000 volumes. Plainfield is also an important industrial centre, its manufactures including printing presses, machine tools, silk and cotton goods, carpets, kid gloves, chamois, clothing, lumber, products, carriages, etc. Population, in 1890, 11,267; in 1900, 15,369.

PLAINTIFF (OF, *plaintif*, complaining, from *plainte*, complaint, from Lat. *placatus*, lamentation, beating of the breast in grief, from *plangere*, to strike). Under the common law system of pleading and modern codes, a person who institutes or maintains a civil action or proceeding against another, who is called the defendant. Where a proceeding is commenced by petition, as in a surrogate's court, the moving party is usually called the 'petitioner.' In many jurisdictions a party commencing an action in equity is called the complainant, but under most systems of reformed procedure no distinction of this sort is made. A plaintiff may be one who prosecutes an action on his own behalf, or who does so as a representative for the benefit of another, in which case he adds to his name a description of his official or representative capacity, as 'A. guardian *ad litem* of B. an infant, etc.'

A person who brings an action in a representative capacity is sometimes called a plaintiff *ad litem*. A person who maintains a proceeding or action in an admiralty court is called a libellant.

Consult the authorities referred to under **PLEADING**.

PLAN. A drawing or design representing a horizontal section of a building. It is distinguished from an elevation which represents a vertical section, and best shows the extent of a structure and the distribution of the area into the component parts.

PLANA, plā'nā, GIOVANNI ANTONIO AMEDEO, Baron (1781-1864). An Italian astronomer. He was educated at the Paris Polytechnic School. He held the chair of mathematics at the Alessandria artillery school, 1803-11, and in the latter year became professor of astronomy at the University of Turin. In 1813 he was made director of the Turin observatory. His most important works are *The Theory of the Attraction of Elliptical Spheroids* (1810) and *Theory of the Movement of the Moon* (1832). He was a member of the French Academy.

PLANA'RIA (Neo-Lat. nom. pl., from Lat. *planarius*, flat). A genus of platyhelminthes (flatworms) characterized by having a flat oval body covered with cilia. They live in fresh water.

PLANCHÉ, plān'shā', JAMES ROBINSON (1796-1880). An English playwright and antiquary, born in London February 27, 1796. He wrote for the London theatres more than 200 successful pieces. His first play was a burlesque, *Amoroso, King of Little Britain* (1818); his last was *King Christmas*, a masque (1871). He was at the height of his reputation from 1840 to 1850, when he was bringing out his burlesques and Christmas pieces for Madame Vestris at the Lyceum. Planché had already gained a reputation for his knowledge of costume and heraldry. In 1829 Planché was elected fellow of the Society of Antiquaries, and in 1843 was one of the founders of the British Archæological Society, to which he contributed many papers. In 1866 he was made Somerset Herald. He died at Chelsea, May 30, 1880. Among his valuable works are *Costumes of Shakespeare's King John* (1823-25); *The History of British Costumes* (1834); *Regal Records* (1838); *The Pursuivant of Arms, or Heraldry Founded Upon Facts* (1852); and *A Cyclopædia of Costume* (1876-79). In 1879 appeared *Extravaganzas* in five volumes, and in 1881 *Songs and Poems*. Planché also published collections of fairy tales translated from the French and German. Consult his *Recollections and Reflections* (1872).

PLANCHE, plānsh, JEAN BAPTISTE GUSTAVE (1808-57). A French critic. He was born in Paris, was educated at the Collège Bourbon, and in 1831 began contributing to the *Revue des Deux Mondes*. He was subsequently connected with the *Journal des Débats* (1832), and was an associate of Balzac on the *Chronique de Paris*. He bitterly attacked the works of Victor Hugo and other writers of the Romantic School. His works include *Portraits littéraires* (1836), *Nouveaux portraits littéraires* (1854), and *Etudes sur les arts* (1855).

PLANCHETTE, plān'shēt' (Fr., little board). A heart-shaped board seven or eight inches at its greatest breadth and length, mounted on two pantograph wheels, about two inches high at its widest part, while a pencil fastened at the apex forms its third support. Placed upon a table with a sheet of paper under it, and one or

two persons with the necessary qualifications having their hands upon it lightly, it begins to move and write answers to questions sometimes of a puzzling character. These answers are asserted by believers in spiritualism to be communications from the spirit world.

PLANCK, plänk, KARL CHRISTIAN (1819-81). A German philosopher, born at Stuttgart, and educated in philosophy and theology in Tübingen. In 1844 he became tutor and librarian at the theological seminary there, and lecturer on philosophy at the university. From 1856 to 1869 he was professor at the gymnasium of Ulm, and in 1879 he became principal of the seminary in Maulbronn. Planck defends in his numerous writings the speculative system of philosophy as opposed to that of empiricism. His chief work is *Die Weltalter* (1850), in which he treats of the system of pure realism and subjective idealism. In his *Anthropologie und Psychologie auf naturwissenschaftlicher Grundlage* (1874), he vigorously combats the theories of the atomists and materialists, and he takes his stand against Darwinism in *Wahrheit und Flachheit des Darwinismus* (1872).

PLANÇON, plän'sôn', POL (1860—). A French basso, born in the Ardennes. He was sent to Paris by his parents and there, despite his own inclinations, entered a business house. Through the friendship of Theodor Ritter he was enabled to study music, and finally entered the Ecole Duprez and devoted himself entirely to music. In 1881 he made his debut in *Les Huguenots* at Lyons. Two years later he appeared at the Paris Grande Opéra as Mephisto in *Faust*, in which rôle, as well as that of Ramfis in Verdi's *Aïda*, his success was pronounced. He created the rôles in Saint-Saëns's *Ascanion*, in Massenet's *Le Cid*, and in Gounod's *Sapho*, upon its revival in 1893. He appeared for a number of seasons at the Metropolitan Opera House in New York, where he was a prime favorite.

PLAN'CUS, LUCIUS MUNATIUS. A Roman politician and soldier. He was born at Tibur, near Rome. In youth he was one of Cicero's pupils in oratory, and later was an officer of Cæsar in the Gallie wars. After the assassination of Cæsar, Plancius at first favored Brutus, but soon went over with four legions to Antonius. In B.C. 42 he was consul with Lepidus. In the contest between Antonius and Octavianus he sided with the latter, and proposed in the Senate to confer upon him the title of Augustus. Plancius was a man of some literary taste, and to him one of Horace's odes is addressed.

PLANE (Lat. *planum*, level ground, plain, neu. sg. of *planus*, level, flat, plane, plain). A surface which is determined by any three of its points not in a straight line. A plane surface is said to have zero curvature. When two planes intersect, their intersection is a straight line. The inclination of one plane to another, or the dihedral angle (see ANGLE) between the planes, is measured by the plane angle whose arms lie in the respective planes and are perpendicular to their intersection. When this angle is a right angle, the planes are perpendicular to each other. As a result of the definition, a plane is determined by a straight line and a point not in that line, or by two intersecting lines or by two parallels. A group of several planes having a com-

mon line of intersection is called an axial pencil. Several planes having a common point of intersection are called a sheaf of planes.

PLANE FIGURES. Any combination of coplanar points and lines is called a plane figure. See POLYGON.

PLANE (OF., Fr. *plane*, from Lat. *planatus*, from Gk. *πλατῆνος*, plane tree, from *πλατός*, *platys*, flat, Lith. *platus*, Skt. *prthu*, broad, from *pruth*, to spread out; so called from the broad, flat leaves), *Platanus*. The only genus of the natural order Platanaceæ, tall, large trees of which there are only four or five species. The flowers are in globose, small, pendulous, long-stalked catkins, which give the tree a peculiar appearance in winter. The species of plane are natives of temperate climates in the Northern Hemisphere; have deciduous large palmate leaves, and smooth whitish bark, which annually scales off in large pieces. The Oriental plane (*Platanus orientalis*), a native of Greece and the East, early used by the Greeks and the Romans as an ornamental tree, is extensively planted for shade and ornament in various regions. Few trees better endure the atmosphere of large cities. A tree is reported on the banks of the Bosphorus, which is 141 feet in circumference at the base, extends its branches 45 feet from the trunk, and is believed to be more than 2000 years old. The wood of the plane, when young, is yellowish-white; when old, it is brownish, fine-grained, takes a high polish, and is esteemed for cabinet-making. The tree thrives best in a rich alluvial soil in the vicinity of water. The North American plane, sycamore, or buttonwood (*Platanus occidentalis*), is very

PLANE TREE OR BUTTONWOOD.

similar and is probably the largest deciduous tree of the United States. It abounds on the banks of the great rivers of the Middle States, where it attains a height of 100 to 150 feet and 10-15 feet in diameter. Its timber is not very valuable, and is very liable to decay. Two other species occur in the Southwest, the Californian sycamore (*Platanus racemosa*) and the Arizona sycamore (*Platanus Wrightii*). The name plane tree is commonly given in Scotland to the sycamore or great maple (*Acer pseudo-platanus*), which resembles the plane tree in its foliage. See MAPLE.

PLANE (Fr. *plane*, from ML. *plana*, plane, from Lat. *planare*, to plane, level, from *planus*,

level, flat, plane, plain). A tool used for rendering the surface of wood smooth and level. It consists of an oblong block of wood or metal with an opening through the centre; this opening is square on the upper side, and is always large enough to admit the cutting instrument; it diminishes down to a mere slit on the under side, just wide enough to allow the cutting edge of the plane-iron and the shaving of wood which it cuts off to pass through. The essential part of the tool is the plane-iron, a piece of steel with a chisel-shaped edge, and a slot in its centre for a large-headed screw to work and to attach to it a strengthening plate. In the older wooden planes it was held in place by the hard-wood wedge. By driving in the wedge, the irons are held very firmly in their place, and they are so adjusted that only the fine sharp chisel-edge of the cutting-tool projects through the slit in the bottom of the body of the plane, so that when the tool is pushed forward by the force of the hand the cutting edge pares off all irregularities, until the wood is as smooth as the under surface of the plane. In the iron planes now used the iron is held in the block and adjusted by a screw. There are many modifications in this tool, which can have its cutting edge and under surface made to almost any contour, so that moldings of all kinds may be made. The two commonest are the jack-plane, for rough work, and the smoothing-plane, for finishing off plane surfaces. For planing machines, see METAL WORKING MACHINERY and WOOD-WORKING MACHINERY.

PLANE CURVE. See CURVE.

PLANE OF POLARIZATION. See LIGHT.

PLANER TREE (named in honor of J. S. Planer, a German botanist of the eighteenth century). A moderately sized elm-like tree (*Plataner aquatica*), found on swampy lands in the Southern United States. It supplies a useful hard timber. *Zelkova acuminata* and *Zelkova crenata*, tall, handsome trees which furnish excellent timber, were formerly included in this genus, which is now considered monotypic.

PLANE SAILING. See SAILINGS.

PLANE-TABLE. An instrument used to fill in the details of topographical work (see SURVEYING), and, on account of the ease and rapidity with which it can be operated, popular where only a moderate approach to accuracy is required. The plane-table consists essentially of a mounted drawing-board bearing an alidade or ruler surmounted by a telescope whose line of sight is parallel in azimuth to the ruler. In orienting the table a declinator, or compass box, and a plumbing arm serve to place a given point on the table over that on the ground which it represents, and to cause a line of the drawing on a paper mounted on the board to lie in or parallel to the vertical plane through its counterpart on the ground. After the paper has been attached to the table it is then leveled and oriented as already described. The observer then sights successively at other different objects in the area under survey, revolving the telescope and ruler in azimuth and drawing corresponding lines along the edge of the ruler at each position. All of these lines pass through the given point and give the angular direction of the different objects in the field. The plane-table is then taken to a second station located at some place previously sighted and whose dis-

tance from the first can be measured by stadia, chain, or tape, and is there set up and oriented as before. The distance from the first station to the second is set off at the desired scale on the line connecting the two points, and the telescope is directed at the same objects as were sighted at from the first station, as well as

PLANE-TABLE.

others not visible from the first point, and new lines are ruled. The instrument is then taken to other points which are given by the intersection of the various lines ruled on the paper, and the positions of the various objects in the area under survey are determined. In this way it is possible to fill in the detail work of a topographical survey with great rapidity and sufficient exactness for most map work. See SURVEYING.

PLANETARIUM (Neo-Lat., from Lat. *planeta*, from Gk. *πλανήτης*, *planētēs*, wanderer, wandering star, planet, from *πλανῆς*, *planēs*, wanderer, planet, from *πλάνη*, *planē*, a wandering; connected with Lith. *plónas*, thin, Lat. *planus*, level, flat, plane, plain). A machine much employed by astronomers in the seventeenth and eighteenth centuries, and first constructed by Huygens and Römer, for the purpose of exhibiting clearly the motion of the heavenly bodies in conformity with the Copernican doctrine. The planetarium exhibited only the orbital motions of the planets about the sun, either in circles or ellipses, and with constant or varying motions, according to the perfection of the machine. It was later improved by the addition of a combination of the tellurian and the lunarian, which exhibited both the motion of the moon about the earth and the earth round the sun, with the principal phenomena (such as the succession of day and night, the varying length of each, eclipses, and the motion of the moon's apogee and nodes) which accompany these motions. A satellite machine was also invented to illustrate the motions of Jupiter's satellites. All these machines were later combined in the orrery (q.v.), which exhibits in the best manner possible the varied motions and phenomena of the bodies in the solar system; but this whole class of instruments have ceased to possess practical usefulness, and have been relegated to astronomical museums.

PLANETOIDS (from Gk. *πλανήτης*, *planētēs*, wanderer, wandering star, planet + *εἶδος*, *eidos*, form), or ASTEROIDS. A numerous group

of very small planets which, with one exception, travel in orbits lying between those of Mars and Jupiter. Till the first year of the nineteenth century they remained undiscovered; but for some years before their existence had been suspected, mainly owing to the remarkable hiatus in the series of the planetary distances when compared with the law of Bode (q.v.). On the first day of January, 1801, the first of them was detected by Piazzi at Palermo, and his success roused the astronomers to search for more planets. Their search was successful, for Olbers (q.v.) discovered two in 1802 and 1807, and Harding one in 1804; but as all researches for some time subsequent to 1807 were unavailing, astronomers gradually allowed themselves to settle down into the belief that no more planetoids remained to be discovered, when the detection of a fifth by Hencke in 1845 revived the hope of fresh discoveries, and from this period no year (excepting 1846) has passed without adding to the list. And since the application of photographic processes to observation, the number known to astronomers has increased with great rapidity. The first photographic asteroid was found by Wolf, of Heidelberg, Germany, December 20, 1891, and was named by him *Brucia*, in honor of Katharine Wolff Bruce, of New York, who contributed to the endowment of the Heidelberg observatory. *Brucia* received the number 323 in the list of planetoids. Since 1892 only a few planetoids have been found visually, though the total number in the list has been extended from 232 to over 500. It will be seen, therefore, that photography has almost completely replaced the visual telescope in this kind of observation.

The magnitudes of the planetoids have not been very accurately ascertained, but it is certain that they are exceedingly small compared even with Mercury, the smallest of the other planets, the diameter of the largest among them having been measured by Barnard as 485 miles, while most of the others are very much smaller than this. They also differ, generally speaking, from the rest of the planets in other respects; their orbits are of greater eccentricity, are inclined to the ecliptic at a greater angle, and are interlaced in a most intricate manner, crossing each other so frequently as to form, when viewed perpendicularly, a kind of network. The consequence of this is that a mutual eclipsing of the sun at different periods by two planetoids must be of very frequent occurrence. After the first two or three of these bodies had been discovered, the opinion was propounded by Olbers that they were but the fragments of some large planet, and this hypothesis received corroboration from the intimate connection which was shown to subsist among them; but this hypothesis is now rejected by most astronomers, and their existence is explained by the nebular hypothesis. See *NEBULE*.

Decidedly the most interesting planetoid is the one discovered August 13, 1898, by Witt of Berlin, and which has received the number 433 and the name *Eros* (q.v.). This small planet possesses the remarkable orbital peculiarity that at perihelion it passes considerably within the orbit of Mars, and thus approaches the earth nearer than any other known body except the moon, and is therefore especially well suited for the determination of solar parallax by the planetoid method. By means of long photographic exposure Wolf and Dugan, during May and June, 1903, dis-

covered eight planetoids, provisionally indicated by 1903, LQ to LX. See *PARALLAX*.

PLANETS. Those solid spherical bodies which belong to our solar system, and revolve in elliptic orbits round the sun. The name planet is of considerable antiquity, and was applied to these dependents of the sun to distinguish them from the other luminous bodies which stud the sky and present to the naked eye no indication of change of relative place (see *STARS*), while the planets seem to wander about among them. The planets at present known are, in the order of their distance from the sun, Mercury, Venus, the earth, Mars, the planetoids, Jupiter, Saturn, Uranus, and Neptune. Six of these, Mercury, Venus, the earth (which was not, however, then reckoned a planet), Mars, Jupiter, and Saturn, were known to the ancients; Uranus was discovered by Sir William Herschel (q.v.) in 1781; and Neptune, after having its position and elements determined theoretically by Leverrier and Adams, was discovered by Galle in 1846. The planetoids of which over 500 are now known, have all been discovered since January 1, 1801. Six of the planets, the earth, Mars, Jupiter, Saturn, Uranus, and Neptune, are attended by one or more satellites; Uranus (generally), Neptune, almost all the planetoids, and all the satellites except our moon, are invisible to the naked eye. The visible planets can be at once distinguished from the fixed stars by their clear, steady light, while the latter have a sparkling or twinkling appearance. The comparative proximity of the planets may be proved by examining them through a telescope of moderate power, when they appear as round luminous disks, while the fixed stars show as mere points of light even in the most powerful telescopes. The planets as observed from the earth move sometimes from west to east, sometimes from east to west, and at times remain stationary at the point where the apparent motion changes from the one direction to the other. This irregularity in their movements was very puzzling to the ancient astronomers, who invented various hypotheses to account for it. (See *PROLEMAIC SYSTEM*; *EPICYCLE*.) The system of Copernicus, by assuming the sun, and not the earth, as the centre of the system, explained with admirable simplicity what seemed before a maze of confusion, by showing that the planetary *apparent* motions are merely a result of real motions belonging to the planets in general and to the earth carrying the observer.

The planetary orbits differ considerably in their degrees of eccentricity, the planetoids, Mars, and Mercury being most, and the larger planets least, eccentric. No two planets move exactly in the same plane, though, as a general rule, the planes of the larger planets most nearly coincide with that of the ecliptic. The latter are consequently always to be found within a small strip of the heavens extending on both sides of the ecliptic (q.v.); while the others have a far wider range. Pallas, one of the planetoids, has an angular elevation of orbit equal to 34° 41' above the ecliptic. According to Kepler's laws (see *ASTRONOMY*), the nearer a planet is to the sun the shorter is the time of revolution. The arrangement of the planets in the solar system bears no known relation to their relative size or weight, for though Mercury, Venus, and the earth follow the same order in size and distance

from the sun, yet Mars, which is farther from the sun, is much smaller than either the earth or Venus; and the planetoids, which are still farther off, are the smallest of all. Jupiter, which is next in order, is by far the largest, being about one and one-half times as large as all the others together; and as we proceed farther outward the planets become smaller and smaller.

With reference to their distance from the sun, as compared with that of the earth, the planets are divided into *superior* and *inferior*; Mercury and Venus are consequently the only inferior planets, all the others being superior. The inferior planets must always be on the same side of the earth as the sun is, and can never be above the horizon of any place (not in a very high latitude) at midnight; they are always invisible at their superior and inferior conjunctions, except when, at the latter, a transit (see TRANSIT OF VENUS) takes place. The superior planets are likewise invisible at conjunction, but when in opposition they are seen with the greatest distinctness, being then due south at midnight.

A trans-Neptunian planet, owing to disturbances produced on the outer planets, is suspected to revolve outside the orbit of Neptune. Even before the discovery of Neptune it was suggested that the Uranian disturbances were not due to a single exterior planet alone. The matter was investigated by Todd (q.v.) in 1877. He computed the probable elements and searched the heavens on "30 clear, moonless nights, between November 3, 1877, and March 5, 1878." Every effort to find the hypothetical planet has, however, so far proved fruitless. Consult Todd's account in the *American Journal of Science* (September, 1880).

In astronomical tables, almanacs, etc., the planets are for convenience denoted by symbols instead of their names, as follows: Mercury, ☿; Venus, ♀; the earth, ♂; Mars, ♀; the planetoids, in the order of their discovery, ①, ②, ③, etc.; Jupiter, ♃; Saturn, ♄; Uranus, ♅; Neptune, ♆; the sun, ☉; the moon, ☾.

For a table of the periods, distances, size, density, etc., of the planets, see SOLAR SYSTEM. See also the several planets under their respective names. For the hypothetical planet Vulcan, see VULCAN; for the elements necessary to determine the orbit of a planet, see ORBIT. For theories regarding the origin of the system, see COSMOGONY; NEBULÆ.

PLANIM'ETER (from Lat. *planum*, level ground, plain + *μέτρον*, *metron*, measure). An instrument for automatically measuring the areas of maps and plans. The first usable planimeter seems to have been constructed in 1814 by a Bavarian engineer named Hermann (1785-1841). This was followed by an ingenious device invented by a Swiss engineer, Opikoff, in 1827, and perfected ten years later by Ernst of Paris. The next notable type was the polar planimeter made by the firm of Amsler-Laffon of Schaffhausen (1854) and known as Amsler's planimeter. This well-known instrument consists of two arms hinged at one end, the outer end of one being a pointed support and that of the other a tracing pencil. The latter arm also bears a graduated cylinder which rolls on the paper, its axis being parallel to the arm. To obtain the area of a figure the instrument is moved bodily about the pointed support on the first arm, while the tracer of the other arm de-

scribes the perimeter of the area, and the graduated cylinder records the required area. This and the 'Wetliche Linearplanimeter,' now manufactured in Vienna, are the best planimeters now made. The mathematical principles involved may be found in works on surveying. The best description of the Amsler planimeter is given in Bauernfeind's *Elemente der Vermessungskunde* (7th ed., Stuttgart, 1890). Consult, also, Amsler, *Ueber die mechanische Bestimmung des Flächeninhalts* (Schaffhausen, 1856). The latest improvements on the polar planimeter have been made by Hohmann and Coradi in their 'Präzisions-Polarplanimeter,' and by Coradi in his 'Kugel-Rollplanimeter,' on which consult Lorber, *Zeitschrift für Vermessungswesen* (vols. viii. and xvii., Stuttgart, 1884, 1888), and Amsler-Laffon, 'Planimeterkonstruktionen,' in the *Zeitschrift für Instrumentenkunde* (4. Jahrg., 1884), and *Das Momentenplanimeter* (Zürich, 1875). For the history of the subject, consult: Trunck, *Die Planimeter; deren Theorie, Praxis und Geschichte* (Halle, 1865); Bauernfeind, in Dinger's *Polytechnisches Journal* (vol. cxxxvii.); and Favaro, in the *Allgemeine Bauzeitung* (1873).

PLANIM'ETRY (from Lat. *planum*, level ground, plain + Gk. *-μετρα*, *-metria*, measurement, from *μέτρον*, *metron*, measure). That portion of geometry which treats of the measurement of plane areas. See PLANIMETER; MENSURATION.

PLANING MACHINE, or **PLANER**. See METAL-WORKING MACHINERY; WOOD-WORKING MACHINERY.

PLANKTON (Neo-Lat., from Gk. *πλαγκτός*, *planktos*, wandering, from *πλάζω*, *plazein*, to wander). A collective term for the free floating or swimming organisms in oceans, lakes, or rivers. The oceanic plankton is more interesting and important than that of lakes and of rivers, inasmuch as it forms the basis for all oceanic life. Among the more important forms which are found in the plant plankton are blue-green algae, bacteria, and diatoms. The colors of certain waters are due to plankton organisms. For example, the Red Sea is colored by a red alga. Diatoms are found in especial abundance in the colder seas. Among the more interesting structures and life habits of the plankton plants there may be noted a high development of adaptations for active movements through the water, a type of structure which is found in plants only among the lower forms. Another very striking feature of the plankton is its periodicity; at various seasons its constitution varies widely and the plankton organisms are known to rise and sink more or less periodically. The mechanism involved in these movements is not known.

In zoölogy the term is restricted to the pelagic life which drifts, the actively swimming surface forms constituting a separate assemblage—the 'nekton.' It consists mainly of 'jellyfishes' (Medusan, Siphonophora, and Ctenophora), ascidian, especially the salpæ (q.v.), and a great variety of pelagic larvæ and minute crustacea with feeble powers of locomotion that are carried along almost passively by the oceanic currents. Much of this occurs in innumerable flocks, and sometimes tinges large areas of the sea by its color, or causes them to glow with phosphorescence; and it furnishes food to many surface-feeding pelagic animals.

PLANQUETTE, plän'kët', ROBERT (1850—). A French composer of light opera, born in Paris. He studied at the Paris Conservatory, and wrote at first mediocre songs. His success came with his adoption of the *Musiquette*, a genre in which he wrote sixteen very successful operettas between 1873 and 1892, one of those best known in America and England being *Les cloches de Corneville* (1877), also known as *The Chimes of Normandy*. Others scarcely less popular are *Nell Gwynne* (1884), *La crémaillère* (1885), and *The Old Guard* (1887), written for the English stage. His music is light and graceful and thoroughly representative of the school which claims as its exponents Lecocq, Audran, Serpette, Banès, Vas-seur, and Victor Roger.

PLANTAGENET. A royal house of England which succeeded to the throne in 1154 in the person of Henry, son of Geoffrey, Count of Anjou, and Matilda, daughter of Henry I. (see HENRY II.), and ruled in the direct male line till 1399. The name of Plantagenet is commonly said to have been applied to Geoffrey of Anjou from his habit of wearing sprigs of broom (*planta genesta*) in his cap. The house gave to England some of its ablest rulers, and the period of the later Plantagenets especially is important for the development of the Parliament and the determination of the general character of English constitutional growth. The monarchs of this line were: HENRY II. (1154-89); RICHARD I. (1189-99); JOHN (1199-1216); HENRY III. (1216-72); EDWARD I. (1272-1307); EDWARD II. (1307-27); EDWARD III. (1327-77); RICHARD II. (1377-99). With the death of the childless Richard II. in 1399 the crown passed to the House of Lancaster (q.v.), descended from John of Gaunt, fourth son of Edward III., and therefore in reality a branch of the House of Plantagenet. The Lancastrian monarchs were forced to contend against the claims of the House of York (q.v.), similarly descended from a son of Edward III. (See also ROSES, WAR OF THE.) The line of York attained the throne in the person of Edward IV. (1461-83), but with the death of his brother, Richard III. (1483-85), the crown passed to the House of Tudor (q.v.).

PLANTAIN (OF., Fr. *plantain*, from Lat. *plantago*, plantain; connected with *planta*, plant) COOKING BANANA, ADAM'S FIG (*Musa paradisiaca*). An herb of the natural order Scitamineæ. It is a native of India, but is widely cultivated in the tropics for its fruits, which resemble those of the banana, but are less sweet and less pleasant to eat uncooked. It is one of the most important of tropical fruits, since a very large part of the human race use it as a principal food. In habit of growth it resembles the banana (q.v.).

PLANTAIN-EATER. Either of two West African birds of the turaco family, Musophagidæ, which have serrated bills and feed on fruits, especially that of the bananas. Both are birds of the size of a crow, are handsomely colored, and form the genus Musophaga. The name is sometimes extended to various other genera. See TURACO.

PLANT-BREEDING. The art of improving plants by crossing and selection. In general plants tend to reproduce their main characters unchanged, but their long recognized tendency to vary has prompted much experimentation, which, with the undirected variation, has resulted in the

production of many cultivated varieties, strains, and races. In some cases the variation appears on a part of a single individual and can be traced to no apparent cause. Such variations are usually called sports, and, when desired, are propagated by artificial asexual methods, which consist of the indefinite propagation of a single individual by cuttings, grafts, layers, etc. This method is one of the simplest and in some respects the surest method of plant-breeding, since as a rule sports are less plastic than other variant forms. The principal objection raised against the method is the weakness supposed to follow long continued asexual propagation. Familiar examples of this type of breeding are the weeping willows and elms, cut-leaved birches and maples, variegated foliage plants, etc. Selection, a second method, consists in the saving of seed from only such individuals as exhibit qualities not possessed by all, undesirable forms being destroyed. Plants grown from seed tend to vary greatly because of the action of diverse factors. As with many varieties of grapes, apples, and other fruits, some seedling may exhibit sufficient merit to be propagated without further selection by the asexual methods mentioned. Usually, however, the progeny shows only a slight improvement over the parent plant, and selection must be continued until the ideal is approximated or an improvement secured that is worth commercial introduction.

Associated with selection, and in many cases preliminary to it, is fertilization which may result, from the transportation of pollen by wind or insects in a natural cross, as in numerous hybrids of oak, willow, etc., occurring in nature. Or there may be an artificial transfer of pollen for a definite purpose. Variations are often introduced by this means and the desirable variant propagated and improved by long continued selection. Since Darwin's time the superabundant nutrition of plants has been held to be a prominent cause of variation. A large part of the work of improving sugar beets, potatoes, tomatoes, cereals, etc., has been along these lines. The usual method of artificial pollination is to remove the immature stamens from the flower to be fertilized unless the pistil is known to be sterile to pollen of the same variety of plant. When the stigmas of the emasculated flower are ripe, pollen from a related plant is placed upon them, and the flower covered with fine gauze or a paper bag to prevent an accidental application of other pollen. When the fruits or seeds are mature, they are collected, and planted when the usual season for planting arrives. From the progeny of such a fertilization individuals that differ from both parents are selected as the basis of new varieties. When a desirable form is found, it is subjected to further cultivation and selection, attention being given to keep the selection always along one line, since any deviation will likely result in the ultimate failure of the experiment. In making selections the individual plant and not any particular portion of it must be the unit of selection. In following out this improvement thousands of individuals will probably have to be discarded. It is said that an American carnation-grower destroyed more than 60,000 plants that he had reared to flowering to secure a single new desirable variety.

In plant-breeding the following principles are laid down: Thorough knowledge of the plant, a preconceived ideal established and maintained throughout, large numbers of seedlings should be

employed in all selection experiments, and fixed characters should be selected as far as possible. A knowledge of the following correlations will aid the plant-breeder: Small foliage is usually associated with small fruit; dwarf seedlings produce poor plants; pale-colored foliage is usually an accompaniment of light-colored fruit, flowers, etc.; large individuals are incompatible with numerous specimens, great productiveness with extreme earliness, and very great size with intense coloration. By paying attention to these principles a skillful plant-breeder can influence almost at will the external characters of form and color and the internal qualities of flavor, perfume, and chemical composition. It is quite as possible, however, for varieties to degenerate under selection as to improve, and this fact shows the importance of making the proper selection and constantly keeping it in mind in subsequent selections.

Hitherto plant-breeders have made great progress in methods of procedure, and have produced many new varieties of fruit, grain, and flowers, but have learned little of the principles controlling and limiting the production of new varieties. Serious efforts are being made by many investigators to establish a scientific basis for plant-breeding experiments. In August, 1899, an international conference of hybridists was held in London under the auspices of the Royal Horticultural Society of England. This meeting, which was attended by many of the leading plant-breeders and scientists interested in the subject, served to arouse activity on the part of many and the literature of the subject has since considerably increased. De Vries, Correns, Tschermak, Bateson, Hays, Spillman, and others have written extensively of their work in the generation of new varieties, and have sought to deduce laws governing the phenomena of variation. This awakened energy led to the almost simultaneous discovery by Correns, De Vries, and Bateson of a paper entitled "Versuche über Pflanzenhybriden," published in 1865 by Gregor Mendel, who showed that nearly constant numerical ratios could be obtained among the types produced by hybridization. As yet the reason why some characters are transmitted and others are not is not clearly understood, but so far as Mendel's work is concerned the approximate proportions in which certain prominent characters will appear in the offspring can be foretold. In the cross-breeding experiments of Mendel two characters were selected, called respectively the dominant and the recessive. If these characters have been well fixed in the parent plant, they will appear in the hybrid offspring in a regular mathematical proportion, which may be represented briefly by the formula 1D: 2DR: 1R. In these D and R continue to exhibit pure dominant and recessive characters and the 2DR furnishes the true crosses which continue to vary in the same proportion as in the formula. This applies to crosses of plants whose ancestors are equally pure and fertile. Most of the exceptions to the so-called Mendellian law can probably be explained by either of these possible sources of error. For a full discussion of Mendel's law, consult Bateson, *Mendel's Principles of Heredity* (London, 1902).

In 1902 a second International Conference on Plant Breeding was held in New York City, under the auspices of the New York Horticultural Society. Papers were read by many of the foremost plant-breeders of the world, and the results

of numerous experiments were shown by the originators of many new varieties of cereals, fruits, and flowers. The papers are printed in the *Transactions of the society* and a brief abstract of them is given in *Experiment Station Record*, xiv., p. 208. For further information, see *New Jersey Experiment Station Report for 1901*, in which the plant-breeding work of the American Experiment Stations is summarized; United States Department of Agriculture *Year Books*, 1897, 1898, 1899; *Experiment Station Record*, vols. vi., xi., xiv., Correns, *Botanische Zeitung*, 1900; De Vries, *Die Mutations-Theorie* (Leipzig, 1901); Weldon, *Biometrika*, vol. i., part 2 (1902); Tschermak, *Zeitschrift für landwirtschaftliches Versuchswesen in Oesterreich* (1900-01); Vernon, *Variation in Animals and Plants* (New York, 1903). See BREEDS AND BREEDING, paragraph *Plant-Breeding*.

PLANT-BUG. Any one of several families of true bugs, which feed upon plants by extracting the sap through the beaks. The Coreiidae are a very large and important family, containing more than 1500 species. The squash-bug (q.v.) of vegetable gardens is a representative of this group, as also is the box-elder plant-bug (*Leptocoris trivittatus*), a species which frequently damages the box-elder trees that, because of their rapid growth, are commonly planted on Western tree claims. The Pyrrhocoridae are a much smaller group, but include several well-known species. The red-bug or cotton-stainer, which does considerable damage to cotton in Florida, as well as to the orange groves, is a prominent example. The family Lygaeidae is another of the largest families of plant-bugs, comprising more than 1300 species distributed in 13 subfamilies and 208 genera. About 175 species are known in the United States. The most prominent member of this family is the chinch-bug (q.v.). The bordered plant-bug (*Stiretus anchorago*) is a brilliant species which preys on the larvæ of the Colorado potato-beetle, and is sometimes called the 'potato-bug enemy.' See COTTON INSECTS. Consult: Comstock, *Manual for the Study of Insects* (Ithaca, 1895); Howard, *The Insect Book* (New York, 1902.)

PLANT-CUTTER. One of the tanager-like birds, related to the cotingas (q.v.), and to the American fly-catchers. They constitute a small family (Phytotomidae), and show some remarkable anatomical peculiarities. The bill is short, strong, conical, with lateral margins finely serrated. The intestine is short, an unusual condition in vegetable-eating birds. They live in pairs or in small flocks and commit depredations in orchards and gardens by cutting off plants, buds, and fruits. They also catch insects. There are three species, all natives of temperate South America, the best-known of which is the 'rara' (*Phytotoma rara*) of Chile, of the size of the common thrush, and of reddish brown and white plumage. It has a short low flight, and a disagreeable rough note. See Plate of COTINGAS, ETC.

PLANTIGRADE ANIMALS (from Lat. *planta*, sole of the foot + *gradi*, to walk). Animals that have the foot so formed that the whole sole touches the ground in walking. Man and the bear are examples. The term is used in opposition to 'digitigrade,' or walking on the tips of the toes, like the horse and dog. Between plantigrade and digitigrade animals all sorts of gradations intervene.

PLANTIN, plān'tān', CHRISTOPHE (1514-89). An eminent French printer, born at Saint-Aver-tin. In 1555 he set up at Antwerp a printing establishment which soon became one of the most celebrated of the time. The most noted of all his publications is the *Biblia Polyglotta* (8 vols., 1568-73). His books were noted for the accuracy of their text and the beauty of their topography and embellishments. Consult Debaecker and Ruelens, *Annales Plantiniennes, 1555-89* (Paris, 1865), and the *Life* by Rooses (Antwerp, 1892).

PLANTIN-MORETUS, MUSÉE. An important museum in Antwerp containing a rare collection, illustrating the art of printing. The names are those of Christophe Plantin, and his son-in-law and successor, Moretus. Plantin's printing office after 1579 was carried on in the present building until 1875, when the house with its contents was purchased by the city. The museum includes a composing room, printing room, and library, with interesting apparatus and specimens of ancient work, and the residence of Plantin, with antique tapestry, furniture, paintings, and porcelains.

PLANT-LOUSE. See APHID.

PLANT PHYSIOLOGY. The study of the functions of plant organs. See PHYSIOLOGY OF PLANTS.

PLANTS (AS. *plante*, from Lat. *planta*, plant). In law, specifically, such vegetable growths as are not included in the terms emblements, crops, or growing trees, except nursery trees. The term includes bushes, shrubs, and nursery trees. Where plants are set out by a landlord they become part of the real estate and cannot be removed by a tenant at the termination of his lease, although he may alter the position of them, or remove a reasonable number of them in the ordinary course of husbandry during his term. Where a tenant sets out plants they become attached to the real estate, unless they are for the purpose of temporary growth and sale, as the trees and other plants in a nursery. For example, a tenant could not remove, at the termination of his lease, berry bushes which were intended to produce annual crops, although he had set them out at his own expense. See EMBLEMENTS.

PLANTS, FOSSIL. See PALEOBOTANY.

PLANT SOCIETY, or ASSOCIATION, or COMMUNITY. An assemblage of plants growing in a common habitat under similar life conditions. See ECOLOGY; DISTRIBUTION OF PLANTS.

PLAQUEMINE, plāk'mēn'. A town and the parish seat of Iberville Parish, La., 85 miles west-northwest of New Orleans; on the Mississippi River, and on the Texas and Pacific Railroad (Map: Louisiana, D 3). It has considerable trade in cotton, lumber, and sugar, and manufactures of lumber and lumber products. The water-works are owned and operated by the municipality. Population, in 1890, 3222; in 1900, 3590.

PLASENCIA, plā-sēn'thē-ā. An ancient but much decayed town of Western Spain, in the Province of Cáceres (Map: Spain, B 2). It is very picturesquely situated on a rocky promontory on the bank of the Jerte, and is surrounded by the remains of a double line of walls with 68 towers. An aqueduct of 53 arches leads into the town, where there is a Gothic cathedral, unfinished and disfigured by late additions. Plasencia

was once a flourishing city; its population in 1900 was only 7965.

PLASMA (Lat., from Gk. *πλάσμα*, formation, molded figure, from *πλάσσειν*, *plassein*, to form). The fluid portion of the blood, rich in proteids. After the removal of the blood from the arteries and veins a part of these proteids separate by coagulation and form the blood-clot, which is composed of fibrin, leaving a fluid poor in proteids, and called the blood-serum.

The term is also given by Haeckel to the protoplasm of cells surrounding the nucleus; or in the case of the monera, which are supposed to have no nucleus, to the unorganized protoplasm constituting such organisms. Cells are defined by Haeckel as bits of plasma containing a nucleus.

PLASMA. A crypto-crystalline variety of quartz that is of a bright green to dark green color. Plasma is somewhat rare, and the best specimens come from India and China. Among the ancient Romans it was highly prized, and was carved by them into ornaments of various kinds, and finely engraved specimens have been found among the ruins of ancient Rome. The variety used by the ancients is believed to have come from Mount Olympus in Asia Minor.

PLASMO'DIUM (Neo-Lat., from Gk. *πλάσμα*, *plasma*, formation, molded figure + *εἶδος*, *eidos*, form.) The vegetable body of a slime mold, consisting of a mass of naked protoplasm sometimes covering several square inches, and crawling about like a gigantic amoeba. It is one of the most favorable subjects for studying the behavior of protoplasm. See MYXOMYCETES.

PLASMOLYSIS (Neo-Lat., from Gk. *πλάσμα*, *plasma*, formation, molded figure + *λύσις*, *lysis*, resolution, from *λύειν*, *lyein*, to loose). The shrinkage of the protoplasm, due to the extraction of water from the cell sap by a solution of

PLASMOLYSIS.

A cell from a filament of alga (*Cladophora*) before (1) and after (2) plasmolysis with sugar solution.

higher osmotic pressure in contact with the cell. The mature plant cell consists of a mass of protoplasm, inclosing one or more droplets of cell sap (vacuoles) and surrounded by a membrane called the cell wall. Under certain conditions, which are also those of activity, the layer of protoplasm is held so firmly against the cell wall

by the osmotic pressure of the substances dissolved in the water occupying the vacuoles that it is usually stretched until its resilience equals the osmotic pressure within (Fig. 1). If such a cell be surrounded by a solution having an osmotic pressure greater than that of the cell sap, water will be withdrawn from the latter, the protoplasm will shrink, and the cell wall, by its elasticity, will follow the shrinking protoplasm until it has reached its unstretched dimensions. If the withdrawal of water still continues, the protoplasm will continue to shrink, but the cell wall may be strong enough to maintain its form. Thus the protoplasm will be withdrawn from contact with the wall, a condition ordinarily taken to indicate the beginning of plasmolysis, but in reality a later stage (Fig. 2). If the cell wall be very thin it may collapse upon the shrinking protoplasm, folding and wrinkling irregularly. Should withdrawal of water continue, the protoplasm may shrink up into a small mass, the vacuole disappearing completely. When the amount of protoplasm in the plasmolyzed cell is relatively small, the protoplasm may happen to divide into two or more parts, a possibility which is taken advantage of for experimentation upon the functions of the nucleus. See OSMOSIS; TURGOR.

PLASSEY, pläs'sè, or **PLASSI**. A small town of British India, on the Bhagirathi River, 75 miles north of Calcutta (Map: India, E 4). It is celebrated for the great victory gained by Clive (q.v.) over the numerically superior forces of Siraj-ud-Daula, Nawab of Bengal, June 23, 1757, a victory which laid the foundation of British supremacy in India. The actual site of the battle has been washed away by the river.

PLASTER. See GYPSUM; BUILDING.

PLASTER, PLASTERING. See BUILDING, section on *Lathing and Plastering*.

PLASTER OF PARIS. A cementing substance which is prepared by partial calcination or dehydration of gypsum. This mineral is chemically a hydrated sulphate of lime and contains 46.6 per cent. of sulphuric acid, 32.5 per cent. of lime, and 20.9 per cent. of water, corresponding to the formula $\text{CaSO}_4 + 2\text{H}_2\text{O}$. When heated to a temperature above 128°C . but less than 360° , gypsum loses a definite portion of its water corresponding to one and one-half equivalents, and then has the composition $(\text{CaSO}_4)_2 + \text{H}_2\text{O}$. The material thus treated is known as plaster of Paris, or commonly plaster, and has the property of hardening or setting when water is added. If the calcination is conducted at a heat greater than 360° , however, the gypsum loses all of its water and becomes inert. The set of plaster of Paris is due to its uniting with water again to form gypsum which assumes a crystalline form.

In the manufacture of plaster of Paris, the gypsum may be quarried and burned directly in kilns, which is the method usually practiced in Europe, or the gypsum may be ground to a fine powder and then calcined in kettles, this being the general practice in the United States. The improved form of kiln consists of a cylindrical chamber with brick or stone walls and a fire-pit at the bottom. The gypsum blocks are loosely placed around and above the fire-pit so that the gases may circulate through all parts of the chambers before passing out of the top of the

kiln. Coal is used as fuel. In the plaster mills of the United States the gypsum is ground in a buhrstone mill or some form of disintegrator and is then run into a calcining kettle set in stonework. The kettle has a diameter of about eight feet and holds about seven tons of ground gypsum. During the process of calcination the powder is stirred by revolving arms so that the whole mass may be burned evenly. Coal and oil are used as fuel. For the purpose of delaying the set of gypsum plaster, which ordinarily requires from six to ten minutes, it is mixed with some form of 'retarder,' such as glue, soda, sorghum, etc., and is then sold as 'cement wall plaster.' The time required for hardening these special plasters varies from two to six hours.

The principal uses of plaster of Paris are for the manufacture of stalf, which is employed in the construction of temporary buildings, and for wall plaster. Owing to its greater hardness and durability, it is much superior to lime for construction purposes. The production of plaster of Paris in the United States in 1901 was 412,908 short tons, valued at \$1,377,570, the greater part being made in Kansas, Iowa, Michigan, and New York. The domestic industry is exceeded only by that of France. Consult Grimsley, "Technology of Gypsum," in *The Mineral Industry*, vol. vii. (New York, 1899). See GYPSUM.

PLASTERS (AS. *plaster*, OHG. *pflaster*, Ger. *Pflaster*, from OF. *plastre*, *plaietre*, *emplastre*, Fr. *plâtre*, *emplâtre*, from Lat. *emplastrum*, from Gk. *ἐμπλαστρον*, *emplastron*, *ἐμπλαστον*, *emplaston*, plaster, from *ἐμπλάσσειν*, *emplastsein*, to plaster, from *έν*, *en*, in + *πλάσσειν*, *plastsein*, to form). Tenacious preparations for external application, solid at ordinary temperatures, but pliable and adhesive at the temperature of the body. Most plasters have as their base a compound of olive oil and litharge, constituting the lead plaster of the pharmacopœia; others owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and fats. These substances, alone or impregnated with medicinally active materials, are spread in a thin layer upon linen, muslin, or leather. Formerly this spreading was done by hand, but of late years the work is accomplished entirely by machinery, which distributes the plaster mass with great evenness, and perforates or makes porous the finished product. Since the introduction of machinery india-rubber has been largely employed in the adhesive composition. There are thirteen plasters recognized by the United States Pharmacopœia: lead, ammonia and mercury, iron, mercury, opium, soap, resin, arnica, capsicum, belladonna, pitch, isinglass, and cantharides, besides many unofficial varieties. Besides their generally protective properties, these plasters have special therapeutic actions dependent upon the active ingredient. Opium plaster, for example, is anodyne, as is also belladonna; lead and arnica are soothing and astringent; mercury, alterative; capsicum is used as a counter-irritant, and cantharides as a blistering agent. Court plaster consists of a solution of isinglass thinly spread upon silk, previously coated with tincture of benzoin. It is employed as a dressing to protect slight cuts or abrasions and must be moistened before application. Gold-beaters' skin is similarly used. In surgery adhesive plaster is extensively used for its mechanical effect to reinforce

weak muscles, to keep dressings in place, to cover ulcers, to limit effusions, etc.

PLASTIDS (from Gk. πλαστός, *plastos*, molded, from πλασσειν, *plassein*, to form), or **CHROMATOPHORES**. Living organs of the cell, usually imbedded in the cytoplasm, of various form, having functions differing according to their ultimate mode of development. They differ from the nucleus in form and composition, and in multiplying by direct division. They are of three kinds—chloroplasts, chromoplasts, and leucoplasts. Chloroplasts (q.v.) contain chlorophyll and carotin, with often other subordinate pigments which add their special tint to the general yellow-green of the ordinary chloroplast; chromoplasts (q.v.) have usually a red or yellow color, due to a predominance of carotin; leucoplasts (q.v.) are colorless and have as their special functions the formation of starch grains, proteid granules, or oil drops, out of material absorbed from the adjacent protoplasm. The oil-formers have been distinguished as elaioplasts. Multiplication of plastids by direct division consists in the severance of the protoplasmic matrix into two parts by its contraction, which continues near the middle until the two portions are completely disjoined. Plastids are minute and undifferentiated in embryos, and take on special form and character under the influence of the external conditions. Thus, plastids which develop near the surface of the plant are likely to form chlorophyll and become chloroplasts; those which develop in subterranean organs or thick aerial parts are likely to become leucoplasts and act as starch or proteid formers; while the plastids in flower leaves, the fruit, or even those in the root (e.g., the carrot) may develop as chromoplasts. See **CELL**; **MITOSIS**.

PLATA, plá'tá, RIO DE LA. The estuary of the combined Paraná and Uruguay rivers (qq.v.) in South America. It forms a large marine inlet between the republics of Uruguay and Argentina (Map: Argentina, J 14). It is 143 miles wide at its mouth and tapers gradually inland for a distance of 200 miles to the delta of the Paraná. The Plata is the outlet for an enormous volume of water, amounting during floods to over two million cubic feet per second. Vast quantities of sediment are also brought down by the two rivers, and are gradually filling up the estuary, which formerly extended more than 100 miles farther inland. Shoals are everywhere forming rapidly, and, together with the strong currents and violent storms, make navigation dangerous. The best natural harbor on the estuary is Montevideo; artificial harbors have been constructed at La Plata and Buenos Ayres by means of jetties projecting beyond the shallows which line the Argentine shore. The Plata estuary was discovered in 1509 by Diaz de Solis, and received its present name ('silver river') from Sebastian Cabot.

PLATĒ'A, or **PLATĒÆ** (Lat., from Gk. Πλάταια *Plataia*, Πλαταιαί, *Plataiai*). An ancient city in the extreme southeastern part of Bœotia, on the borders of Attica, at the foot of Mount Cithæron. Involved in war with its powerful neighbor Thebes, it sought help of the Spartans and was referred to Athens, as a nearer ally, apparently about B.C. 500. Received and defended by the Athenians, the Plataeans showed their gratitude by coming with their whole force to the help of

the Athenians at Marathon. For this they suffered severely in B.C. 480 when Xerxes destroyed the town. The great victory of the Greeks near the town in the following year restored them under a national agreement that guaranteed their independence. Their devotion to Athens brought on them the hatred of the Thebans, who made an unsuccessful attempt to take the town by surprise in 431, at the opening of the Peloponnesian War, and when it was finally forced to surrender to the Spartans (B.C. 427) after two years' siege, secured the death of the defenders. Restored after the Peace of Antalcidas (B.C. 387), it was once more destroyed by the Thebans in 373. Finally under Alexander the Great it was again rebuilt, but sank into insignificance, though it was still of some importance in the time of Justinian, who rebuilt its walls. The present walls seem to belong to the later city and inclose a much greater circuit than can have belonged to the fifth-century town. For a full discussion of the topography of the neighborhood, with detailed maps, consult Grundy, *The Battle of Plataea* (London, 1894).

PLAT-BAND (Fr. *platband*, *plattbande*, OF. *plattebande*, lintel, flat band). In architecture, a flat fascia or band, with less projection than breadth, between curvilinear moldings.

PLATE, SHEFFIELD. A kind of table ware made by coating a baser metal with silver. Previous to the introduction of electro-plating, the method generally pursued was that which has acquired the name of *Sheffield plating*, from the large extent to which it was carried on in that town. It consisted in soldering on to one or both sides of an ingot of the baser metal a thin plate of silver. The ingot is always of an oblong shape, and is most carefully prepared on the surfaces which are to receive the silver, so that nothing shall prevent the complete union of the two. The soldering is a process requiring much care and nicety; the plates of silver are thinly coated with a concentrated solution of borax, and are then applied to the prepared surfaces of the ingot, to which they are firmly bound with iron wire, and then placed in the *plating-furnace*, and subjected to a strong heat. This furnace is so arranged that the interior can be constantly watched, and when the proper temperature is attained the workman knows the exact instant to withdraw it. The act of soldering is almost instantaneous, and fusion would immediately follow if the ingot was not quickly withdrawn. When cooled, the wire is taken off, and the ingot is taken to the rolling-mill, where it is passed backward and forward, of course with the silver above and below, until it is rolled out into a sheet of the exact thickness required. However thin it may be made, it is found that the relative thickness between the ingot and its layers of silver is always the same. Practically all plating of metals is now performed by the process of electroplating. See **ELECTRO-CHEMISTRY**, **INDUSTRIAL**; **TABLEWARE**, **SILVER-PLATED**.

PLATEAU, plá-tó' (Fr., diminutive of *plat*, plate). An elevated area of fairly level land with approximately horizontal strata. The chief difference between a plain and a plateau is that the plateau is higher; but this very difference in altitude gives the streams a chance to cut deeper valleys than in a plain. Plateaus are almost uniformly associated with mountains, being

great blocks of strata uplifted during mountain folding with little disturbance of the layers. Thus the uplift that formed the Western Cordilleras raised the plateau known as the Great Plains, which rises gently from the Mississippi to an elevation of 4000-6000 feet at the base of the Rockies; the Colorado Plateau, between the Rockies and the Sierra Nevada, 6000-9000 feet high; and the Columbia Plateau of Oregon and Washington. West of the Appalachians, and uplifted with them, is the Allegheny Plateau, 2000 feet or more in height, which extends from eastern New York to Tennessee and includes hilly central New York, western Pennsylvania, West Virginia, eastern Kentucky, and Tennessee. The uplift of the Himalayas has formed the lofty plateau of Central Asia, which rises from 10,000 to 13,000 feet. Plateaus are frequently so sculptured by denudation as to resemble mountains in form as well as in height, as in the case of the Catskills, a part of the Allegheny Plateau. Their tops, however, form an even sky line, their strata are nearly horizontal, and it is only the excessive denudation, carving deep valleys, that has given them the mountainous appearance. For such dissected plateaus the name pseudo-mountains has been proposed. Where sculptured plateaus are adjacent to mountains it is often difficult to tell where the plateau leaves off and the true mountain begins.

Because of their elevation, plateau streams have great cutting power and often form deep gorges, and, in arid regions, cañons, of which the best example is the Grand Cañon of the Colorado. In arid regions the plateau topography is typically angular. The walls of the cañons consist of alternate precipices and talus slopes, as resistant and weak rock layers are encountered, and between the streams are flat-topped areas, capped by resistant strata, and known in Western America as mesas if large, and as buttes if small. It is this flat-topped condition of the plateau, faced by steep slopes, that has given rise to the name tableland as a synonym for many plateaus in arid lands. Plateaus, in moist climates, where the work of weathering and erosion is greater, are far less rugged and angular.

By reason of their height, plateaus are generally cool, and, because of their association with mountains, they are often arid, having rain-bearing winds cut off by the higher land near by. Plateaus are not infrequently deserts, for other reasons. The high plateau region of Africa and Arabia, for example, is traversed by the drying trade winds the year round and has little or no vegetation. Often the only parts of a desert plateau capable of supporting human life are the alluvial fans, on which streams flow from the adjacent mountains for a short distance before losing themselves in the sand. Portions of many plateaus, for example that of the Columbia, would be capable of cultivation if the water could be led out of the cañon valleys. In temperature there is often great range, from the warm base to the cool or cold top. This is well illustrated in the plateau of Mexico, which rises from a tropical climate to that of the cool temperate zone. Difference in temperature is accompanied by a decrease in evaporation and an increase in precipitation, so that the tops of high plateaus are often forest-covered, as in the case of the Colorado Plateau, which rises from the desert region of western Arizona.

When the strata of deeply dissected plateaus contain mineral deposits, like the coal of western Pennsylvania and West Virginia, they are important mineral-producing regions, because the mineral deposits are exposed where the deep valleys cut into the horizontal strata. In the Allegheny Plateau such valleys have cut down fully 1000 feet, while in the Colorado Cañon the horizontal layers are revealed for over 6000 feet. Agriculture is not usually highly developed on plateaus, partly because of the climate, partly because of the ruggedness. Grazing is the most widespread industry on arid plateaus, as in the Western United States, where large areas are occupied only by scattered ranchmen. Consult: Davis, *Physical Geography* (Boston, 1898); Tarr and McMurry, *Physical Geography* (New York, 1897). See MOUNTAIN.

PLATEAU, JOSEPH ANTOINE FERDINAND (1801-83). A Belgian physicist. He was born in Brussels and was educated at Liège. At the foundation of the University of Ghent in 1835 he became professor of experimental physics and astronomy, a position he occupied until 1871. His researches were largely carried on in the field of optics and he devised the anorthoscope and other apparatus. His work is most remarkable inasmuch as much of it was accomplished while he was suffering from total blindness brought on by experimental work about 1840. He invented the experiment which has since been known by his name to illustrate molecular forces, in which a mixture of alcohol and water is made of the same density as olive oil and a drop of the latter placed in it. The oil will assume a spherical shape, to which it will always return. He also originated the interesting experiment in which wire frames are immersed in soapy water and then films produced which intersect in straight, sharp lines. These and other experiments are described in *Statique des liquides soumis aux forces moléculaires*, published in 1873. Professor Plateau also prepared a bibliography of the subjective phenomena of vision to the end of the eighteenth century.

PLATED WARE. See TABLEWARE, SILVER-PLATED.

PLATE MARKS, or HALL MARKS. The legal impressions made in Great Britain on watch-cases, jewelry, and gold and silver plate, after the material has been assayed at the various Government assay offices. In the case of jewelry the marks are, with a few exceptions, optional. There are four distinct kinds of plate marks: (1) the standard or quality mark, (2) the mark of a particular office at which the article was assayed, (3) the mark by which the date of marking may be ascertained, and (4) the maker's private mark. Formerly if the article was dutiable the head of the reigning sovereign was also added, but in 1798 watch-cases were exempted from this rule, and in 1890 the practice was entirely abandoned. The standard mark of the London office is a lion passant  for sterling silver; a crown

with the figures 22  22 for 22-carat gold; and the crown with the figures 18 for 18-carat gold. Up to 1845 a lion passant was likewise the standard mark of 22-carat gold, and from 1697 to 1723, during which time the quality of standard silver was raised from .925 to .959, the

standard mark was a lion's head, and the hall mark a figure of Britannia. The standard mark at Edinburgh is a thistle ; at Glasgow, a lion rampant ; at Dublin, a harp crowned , with the figure 22 added in the case of 22-carat gold.

The hall marks of some of the particular assay offices are: London, a leopard's head, crowned up to 1823 ; Edinburgh, a castle ; Glasgow, a tree, a fish, and a bell ; Dublin, a figure of Hibernia ; Chester, a sword between three wheat sheaves ; Birmingham, an anchor  . In addition,

the Sheffield office is designated by a crown; Exeter, by a castle with three towers; York, by five lions on a cross; and Newcastle, by three castles.

The date-marks of the Goldsmith's Hall, London, which are changed annually on May 30th, are the first 20 letters of the alphabet, each series differing in some slight detail (either in the style of the letter or in the shape of the shield on which they are placed) from a former series. The date-marks of Birmingham, which are changed annually in July, are also letters of the alphabet.

The character of the maker's mark was optional up to 1697, when it was fixed as the first three letters of his surname. Since 1739 the mark has been the initials of the maker's Christian name and surname. Watch-cases of foreign make when marked in Great Britain bear special stamps. In Switzerland there are various plate marks, but the regulations concerning them are not comprehensive, and English marks are accepted in place of the Swiss.

PLATEN-HALLERMUND, plät'en häll'ēr-mūnt, AUGUST, Count (1796-1835). A distinguished German poet, born at Ansbach. Educated in the Corps of Cadets and the Pages' Institute at Munich, he entered the Bavarian army in 1814, took part in the campaign of 1815, but, wearied afterwards by the dreary monotony of garrison duty, he obtained a furlough and, provided with a stipend, devoted himself to philological and philosophical studies, first at Würzburg (1818-19), then until 1825 at Erlangen, where Schelling exercised a lasting influence upon him. He had early turned to Oriental studies and as a fruit thereof published in 1821 *Ghaselen*, a collection of poems in Oriental forms, which was followed in 1824 by *Neue Ghaselen*, both series winning a favorable comment from Goethe. A visit to Italy in 1824 inspired *Sonnette aus Venedig* (1825), the finest collection of sonnets in the German tongue, remarkable for classic beauty of form. Bitterly opposed to Romanticism as he found it, he appears nevertheless under romantic influence in his dramatic poem *Der glä-*

serne Pantoffel (1824), welded out of the fairy tales of Cinderella and Snowdrop, in the comedy *Der Schatz des Rhampsinit* (1824), and in his later epic *Die Abbassiden* (1834), based on stories from the *Arabian Nights*. The extravagances of German Romanticism, however, kindled his wrath, and he satirized the 'fate tragedy' effectually in *Die verhängnissvolle Gabel* (1826), a fork here taking the place of the dagger by which, in the typical fate tragedy, the family ancestress comes to grief, and a dozen descendants being stabbed by the 'fatal fork' before the close of the drama. The command of language and mastery of versification distinguishing this literary comedy are even excelled in *Der romantische Edipus* (1829), directed more especially against the lack of form in Romanticism and its tendency to experiment with new and unwieldy metres, the chief target of Platen's satire here being Immermann (q.v.), parodied as "Nimmermann." In 1826 Platen had made Italy his permanent home and thence only twice visited his native land. During his last sojourn in Germany in 1833 he published the historical drama *Die Liga von Cambrai* and *Geschichten des Königreichs Neapel von 1414 bis 1443*. He died at Syracuse, Sicily. Platen was no genius, but a poet of exquisite taste, whose later verses are models of formal virtuosity in their complex rhythms and technical polish of rhyme. His best biography is to be found in his *Tagebücher*, edited by Laubmann and Sehefler (Stuttgart, 1896-1900). Consult also: Minckwitz, *Graf Platen als Mensch und Dichter* (Leipzig, 1838); Gildersleeve, *Essays and Studies* (New York, 1890); Besson, *Platen, étude biographique et littéraire* (Paris, 1894); and Greulich, *Platen's Litteraturkomödien* (Bern, 1901).

PLATHANDLER, plät'händ'lēr. A Dutch name in South Africa for the curious clawed toad (*Xinopus calcaratus*), which is distinguished by having strong metatarsal claws and minute eyes. These small frogs, which are tongueless, are peculiarly aquatic, never leaving the water except when forced to change their locality on account of drought or scarcity of food. Specimens have been naturalized in England, where their habits and methods of breeding have been well studied. Consult Gadow, *Amphibia and Reptiles* (London, 1901).

PLATINA, plät-tē'nà, BARTOLOMMEO DE (1421-51). An Italian humanist and historian. He was born at Piadena (Lat. form Platina, hence his name), near Cremona. His family name was Sacchi. In 1464 he became an abbreviator at the Papal courts, but with many of his colleagues was removed the same year on the accession of the new Pope, Paul II. For his boldness in pleading that the abbreviators held their office for life he was imprisoned for four months, and again in 1468 on the charge of conspiracy. Sixtus IV. appointed him superintendent of the Vatican library in 1475, and he retained the position till his death. At the invitation of Sixtus he wrote the lives of the popes, from Saint Peter to Paul II. inclusive. This work, originally in Latin, was published at Venice in 1479, and has been repeatedly reprinted and translated. The later portions, which rest upon the testimony of contemporaries and his own experience, are considered the best. The English translation of 1685 was revised by Benham and published in the *Ancient*

and *Modern Library of Theological Literature* (2 vols., London, 1885).

PLATING. See ELECTRO-CHEMISTRY, INDUSTRIAL; and ELECTRO-PLATING.

PLAT'INIRID'IUM (Neo-Lat., from *platinum* + *iridium*). A native alloy of iridium with platinum and allied metals that crystallizes in the isometric system, has a metallic lustre, and is silver-white in color. It is found chiefly with platinum ores in the Urals and in Brazil; also in the gold alluvial deposits of the Pacific Coast.

PLATINUM (Neo-Lat., from *platina*, from Sp. *platina*, platinum, from *plata*, silver, plate, from *plato*, flat, from Gk. *πλάτεις*, *platys*, flat, wide, broad; connected with Lith. *platus*, broad, Skt. *prthu*, wide, from *prath*, to spread out). A metallic element, the existence of which was first made known in Europe by Antonio de Ulloa in 1736. It was first described by Watson in 1750. It is found native, usually alloyed, however, with iron, palladium, rhodium, iridium, osmium, and other metals, generally in grains and scales in alluvial deposits in South America, the Urals, in Borneo, Santo Domingo, and New Zealand; also in small quantities in the gold washings of the Pacific Slope. A few irregular lumps or nuggets have been found, one of which, now in the Demidoff cabinet in Saint Petersburg, weighs 7837 kilograms. For the preparation of pure platinum the commercial metal may be melted with 6 parts of pure lead and the finely divided alloy treated with dilute nitric acid. The residual black powder may then be dissolved in dilute aqua regia, the solution precipitated with dilute sulphuric acid, and the filtrate further precipitated with an excess of ammonium chloride and some common salt. This precipitate is in turn heated with the acid sulphates of potassium and ammonium, and on cooling the resulting mass is treated with hot water, which leaves nothing but pure platinum behind. The commercial metal is usually obtained by a somewhat complicated wet process, although it is possible to obtain it more or less pure also by a dry process.

Platinum (symbol Pt.; atomic weight, 194.89) is a grayish-white metal with a specific gravity of 21.48 at about 17.6° C. It fuses at about 2000° C. (3630° F.). It is very malleable and ductile, becoming soft and workable at a temperature far below its melting-point. Wires have been drawn that are one twelve-hundredth of an inch in diameter. Molten platinum absorbs oxygen, which it gives off when rapidly cooled. Red-hot platinum also occludes hydrogen, to the extent of about five times its own volume, and retains it indefinitely after cooling. *Spongy platinum* is finely divided metallic platinum which possesses a very large surface compared with its mass and is able to condense large quantities of oxygen. It is readily prepared by igniting ammonium-platinum chloride. It forms a porous mass which may be polished with a burnisher. Of similar nature is *platinum black*, that is usually prepared by heating a solution of platinum chloride in potash and alcohol. It absorbs more than 800 times its volume of oxygen. Platinum forms alloys with most of the metals, some of which, such as the alloy with 10 per cent. iridium, have found use in the arts, especially for the purpose of making standard weights and measures. Metallic platinum is employed in making crucibles and similar utensils for labora-

tory use, and as it is not attacked by acids, vessels of it have been used in sulphuric acid works. It also finds extensive application in the manufacture of incandescent electric lamps, being the only metal that can be used to pass through the glass lamp bulbs making a tight joint. Methods have been proposed for its electrolytic deposition, but they have not been generally adopted. It has been used in Russia for the coinage of high values of money. During 1900 400 Troy ounces of metallic platinum, valued at \$2500, were mined in the United States.

Platinum combines with oxygen to form a platinum oxide or monoxide (PtO), which gives rise to a series of platinum salts, a platinum-platinic oxide (Pt₂O₄), and a platinum oxide or dioxide (PtO₂), which yields a series of platinic salts. The most important of the platinum salts is the platinic chloride or platinum tetrachloride, which is a brownish red deliquescent salt, a solution of which is used in the laboratory as a reagent. Of considerable interest to the chemist are also the so-called platinum bases, which are compounds of platinum salts with ammonia.

METALLURGY. The extraction of platinum from the ore consists first in concentrating the ore by washing; the further treatment may be conducted either in the wet way or the dry way. The dry method does not produce pure platinum, but its alloys with iridium and rhodium, and the production of pure platinum requires the use of the wet method. Electrolysis is used to separate metallic platinum from its alloys with gold. Two methods of dry extraction have been used. One consists in melting the ore in a vessel made of lime and remelting the button thus obtained; the second method is to melt the ore with galena and litharge in a reverberatory furnace and scoriafy the lead-platinum alloy obtained in order to remove the lead. Finally the platinum is fused into an ingot in the lime furnace. The wet method of extraction consists essentially in bringing platinum into solution with aqua regia, precipitating from this solution platinum-ammonium chloride by means of ammonium chloride and ammonia, and then decomposing the compound and separating the platinum at red heat. The wet method is the principal method of platinum refining now employed. Physically metallic platinum has an almost silver white lustre, is ductile and malleable in a high degree, is about as hard as copper, and has a tenacity between that of gold and of copper. For a concise treatment of the metallurgy of platinum, consult: Howe, *Bibliography of the Metals of the Platinum Group, 1748 to 1896* (Washington, 1897); Schnabel, *Hand-book of Metallurgy* (New York, 1898).

PLAT'NER, JOHN WINTHROP (1865—). An American theologian and Church historian, born in Lee, Mass. He graduated at Yale University in 1885, and at Union Theological Seminary in 1893, studied in Berlin, then was instructor in Union Seminary (1895-96), in 1896 became assistant professor of ecclesiastical history at Harvard, and in 1901 accepted a similar chair at Andover Theological Seminary. He contributed articles on historical theology to the *New International Encyclopedia*.

PLATNER, SAMUEL BALL (1863—). An American classical scholar, born in Unionville, Conn., and educated at Newark Academy and

at Yale University. After five years as instructor in Latin and French in Utica, N. Y., in 1890 he became assistant professor of Latin in Western Reserve University, where he became full professor in 1892. He was chosen secretary of the managing committee of the American School of Classical Studies in Rome in 1898, was professor there in 1899-1900, and for the year 1900-01 was president of the American Philological Association. He wrote *Selections from the Letters of the Younger Pliny* (1894) and *The Topography and Monuments of Ancient Rome* (1903).

PLATO (Lat., from Gk. πλάτων, *Platōn*) (c.427-347 B.C.). A Greek philosopher, born probably May 7, B.C. 427, on the island of Ægina, a dependency of Athens, where his father held an estate. His real name was Aristocles. His father claimed descent from Codrus; his mother, Perictione, from Solon. The known facts of his life are few. He received the education in music and gymnastics of a well-born Athenian youth, under the limitations imposed by the virtual state of siege created for Athens by the Peloponnesian War. His writings are sufficient evidence that he absorbed all the culture of his age; poetry, art, pre-Socratic philosophy, the Sophistic enlightenment (see SOPHISTS) in a synthesis, as Emerson says, "without parallel before or since." We may believe the tradition that he distinguished himself in gymnastics and wrote poetry. The poems he is said to have burned when, at the age of twenty, he experienced the higher inspiration of the philosophic muse through Socrates.

For a youth of Plato's birth and endowments, politics would have been the natural career. Two of his dialogues are named from his kinsmen Charmides and Critias, who were prominent in the oligarchy of the so-called Thirty Tyrants which dominated Athens in the year 404-03. The experiences of that year disenchanting him forever with regard to the rule of the 'Fair and Good,' as they called themselves. The judicial murder of Socrates by the restored democracy in the year 399 and the increasing license and weakness of popular rule through the fourth century further embittered his spirit and developed the conviction that all existing forms of government were mere partisan factions, and that there was no hope of salvation for the cities of Greece until "either philosophers should become kings or kings philosophers." The philosopher whose lot was cast in fourth century Athens could exercise active citizenship only in the city of the ideal, "of which a pattern is laid up in heaven"—the City of God of later Græco-Roman and early Christian idealism. The powers and social aspirations that might have made a great statesman and leader of men found expression in the *Republic* and *Laws*, the masterpieces of Plato's maturity and old age. After the death of Socrates Plato is said to have left Athens and to have traveled extensively in Greece, Southern Italy, Sicily, and even Egypt and Northern Africa. About the year 388 he is said to have visited the court of Dionysius the Elder, tyrant of Syracuse, who, offended by his freedom of speech, contrived to have him sold into slavery at Ægina on his voyage home. The story adds that he was at once ransomed by friends. Modern conjectural scholarship tries to trace in Plato's writings the chronological succession of Megarian, Italo-Pythagorean, Egyptian, and Sicilian influences experi-

enced in these voyagings. But we really know nothing beyond the presumption that he was much absent from Athens during the ten years that followed Socrates's death. At the age of forty, about the year 387, he established the 'Academy,' which, with the rhetorical school of Isocrates, made Athens in very deed the 'educator of Hellas,' and was the beginning of that 'university life at Athens' which continued for eight centuries. The name is derived from the hero Academus, adjoining whose shady precinct and gymnasium on the road to Eleusis, one mile from Athens, was the small estate which Plato dedicated to the uses of the school. By Plato's will, the institution was probably perpetuated as a religious foundation sacred to the Muses, and this organization was imitated in the Lyceum of Aristotle, the 'garden' of Epicurus, and the Museum of Alexandria. Here for forty years he taught, debated high and subtle questions with his favorite pupils, and "curled and combed the style of his dialogues" until his death in the year 347. Among his most famous pupils were Speusippus, his nephew, who succeeded him as scholar; Xenocrates, the successor of Speusippus; Aristotle (from the year 367), the orators Demosthenes, Hyperides, and Lycurges, the astronomer Eudoxus of Cnidos, and many other eminent men from all parts of Greece. The inner life of the school we can only divine. From Plato's sneers at the Sophists, who took pay for spiritual gifts, we may infer that no tuition fees were exacted. We may conjecture that some of the most abstract and metaphysical dialogues, as the *Parmenides*, the *Sophistes*, the *Politicus*, the *Philebus*, are idealizations of actual discussions in the school, as the *Charmides*, *Lysis*, *Protagoras*, and *Gorgias* are reflections of real conversations in the gymnasias and public resorts frequented by Socrates. A famous passage of the *Phædrus* exalts the spoken above the lifeless written word, and Plato, like those two other great artists in language, Renan and Ruskin, affected to hold mere literary virtuosity in light esteem. Contemporary writers of comedy represent the students of the Academy as dandified young coxcombs, and jest about the obscure 'idea of good,' and the scientific definition of the cucumber by dichotomy, much as the paragraphist of the modern newspaper alludes to transcendentalism and the 'beanfulness of the bean.' From this remote and sphered course, Plato was drawn into the turmoil of real life by his two visits to Syracuse in the years 367 and 366 and shortly after. The younger Dionysius had succeeded his father as tyrant of Syracuse, and Dion, his kinsman by marriage, whose friendship Plato had won in his first visit, cherished the illusion that, under suitable guidance, the youthful ruler might develop into the philosopher king postulated in the *Republic*. The failure of the experiment, the banishment of Dion as its result, the expedition organized in the year 359 by Dion with the aid of pupils of the Academy against Dionysius, whom he drove into exile in turn, his assassination by his fellow pupil Callippus, and the anarchy into which Syracuse was plunged as a consequence, furnished abundant matter for those inclined to blaspheme philosophy and scoff at the scholar in politics, and may plausibly be conjectured to have contributed to the mood of embitterment and disillusion that prevails in the great work of Plato's declining years, the *Laws*.

The pathos of Plato's old age has been beautifully expressed by Wilamowitz (*Aristoteles und Athen*, vol. i., p. 330). But credible anecdotes illustrative of the esteem and love in which he was held by his fellow citizens and numerous pupils soften the picture. If some illusions were gone, the grasp of thought and the synoptic command of experience remained to the end, and in reading his later works we feel that, like the aged Cephalus in the *Republic*, the man stands on the heights of a noble life "with a glimpse of a height that is higher." The *Laus* lacks the inimitable Attic grace of the *Symposium* and the *Phædo*, but the thoughtful reader finds compensation in the breadth of its survey of human life and Greek institutions, its intense moral and religious earnestness, the solemn detachment of its resigned and stately melancholy. As Jowett finely says: "The wings of his imagination have begun to droop, but his experience of life remains, and he turns from the contemplation of the eternal to take a last sad look at human affairs."

Plato's extant writings (including probably all he ever published) are arranged by the rhetor Thrasyllus (first century A.D.) in nine tetralogies or groups of four. One member of the ninth group is constituted by the thirteen letters which are almost certainly spurious, though some historians now defend the genuineness of the seventh epistle because of the interesting and plausible account which it gives of Plato's relations with the court of Syracuse. Of the thirty-five dialogues, the *Hipparchus*, on the love of gain; the *Erastus* and the *Theages*, on philosophy; the *Minos*, on law; and the *Epinomis*, a sort of supplement to the *Laus*, are generally acknowledged to be spurious. Many reputable scholars still doubt the genuineness of the *Aleibiades I.*, on the nature of man; the *Alcibiades II.*, on prayer; the *Hippias I.*, on the beautiful; the *Hippias II.*, on falsehood; the *Ion*, on Homer and poetical inspiration; the *Menexenus* or Funeral Oration; and the *Kleitophon*, a fragment. The acceptance or rejection of these seven minor works affects very slightly our total impression of Plato's thought and art.

The dialogues vary in length from the twenty-two pages of the *Crito* to the four hundred and eighteen pages of the *Laus*, and in manner from the lively dramatic representation of a possible conversation in a Greek gymnasium (the *Lysis* on Friendship, the *Charmides* on Temperance), to the didactic exposition in perfunctory dramatic form of an obscure problem of logic or metaphysics (*Sophistes*, *Parmenides*), a theory of the universe (*Timæus*) or a project for the reformation of society, education, and law (*Republic*, *Laus*). The dialogue form arose naturally out of the Greek drama, the Athenian habit of discussion, and its practice by Socrates. Its history has been written by Hirzel (*Der Dialog*, Leipzig, 1895). It was employed by other disciples of Socrates as well as by Plato, and specimens of such dialogues are included in Xenophon's *Memorabilia* of Socrates. The form is sometimes purely dramatic, as in the *Euthyphro* on holiness, or the *Gorgias* on rhetoric; sometimes, as in the *Republic*, it is that of a narrated dialogue, which permits description and comment as in the modern novel. Socrates is the principal speaker in all except the *Sophistes*, *Politicus*, *Parmenides*, *Timæus*, *Critias*, and the *Laus*, in which last he does not appear at all.

One of the chief problems of recent Platonic

scholarship is the determination of the dates of the dialogues through statistical study of the style (Lutoslawski, *Origin and Growth of Plato's Logic*), by tracing the development of Plato's thought, or by the aid of casual historical allusions. The results, though affirmed with confident dogmatism, cannot be verified. The *Laus* and *Timæus* are known to be late. The *Republic* belongs to Plato's middle age. The minor dramatic dialogues are presumably as a whole early. The severely metaphysical *Sophistes*, *Politicus*, and *Philebus* probably follow the *Republic* rather than precede it, as older scholars believed. But the unity and consistency of Plato's thought as a whole, and the tradition that he revised and corrected his greater works to the end, lessen the significance of these researches.

The perennial charm of Plato resides precisely in the baffling combination which he presents of consummate artist and subtle metaphysician. We may say roughly that the dialogues have three chief aims: (1) The ideal portraiture of the master Socrates (see SOCRATES); (2) the dramatic portrayal of the practice of discussion, the 'game of question and answer,' as it has been called, which played so large a part in Athenian life; (3) the exposition of doctrine. Plato is the Shakespeare of ideas. All ideas are allowed to speak for themselves on his stage with something of the dramatic fairness that seems to justify every personage, from his own point of view, upon the stage of Shakespeare. And though it is not so difficult to determine in this dramatic conflict of ideas the beliefs seriously defended by Plato as it is to observe the habitual preferences that define Shakespeare's personality, it is still very difficult. The hasty reader will accept as Platonic definitions distinctions, arguments, and fallacies that have a purely dramatic significance. He will interpret as marking stages in the development of Plato's own thought professions of ignorance or bewilderment which the Socratic irony employs merely to ensnare pretentious self-sufficiency, to stimulate youthful thought, or as a dramatic prelude to the favorite Socratic moral: "Let us re-examine the whole question together." He will take literally Socrates's affectation of following whithersoever the wind of discussion may blow, and, dazzled by the kaleidoscopic shiftings of suggestion and interesting ideas, he will be skeptical of the existence of any underlying unity of thought and purpose.

Instead of falsifying Plato's teaching by forcing it into the framework of an artificial system, it is better simply to enumerate a few of the dominant conceptions and aims that preserve its unity and consistency amid all its apparent variations. There is first dialectic—the faith which he shared with Socrates in the value of rational discussion, if not as the organon of absolute truth, at least as the only protection against the errors and confusions of untested opinion. Both Plato and Socrates believe that, as John Stuart Mill phrases it, "there is no knowledge, and no assurance of right belief, but with him who can both confute the opposite opinion and successfully defend his own against confutation." Many of the most entertaining passages of the dialogues are mere dramatic illustrations of the inability not only of the average man, but of the most brilliant sophists and rhetoricians of the day to do this (*Gorgias*, *Protagoras*). They could bandy abstractions implying praise or

blame, and discourse eloquently of virtue and the education that fitted men for life. But they could not define the terms they used, or defend the coherency and consistency of their opinions against objectors. They were unable to make the preliminary distinctions and classifications requisite for the intelligent discussion of such questions as 'Can virtue be taught?' (*Meno*) or 'Is pleasure or knowledge the good?' (*Philebus*). They had opinions, but no knowledge. Dialectic was said to have been 'invented' by Zeno, the author of the famous fallacies disproving motion; and the Athenians of the fifth century were subtle and skillful disputants. But the rules of the game (the principles of elementary logic) had never been formulated, and Socrates was the first to play it with system and conscious mastery. He demanded definitions of general terms and confirmed or refuted them by apt induction and generalization from simple pertinent instances. So great was his skill that, as Xenophon affirms and Plato illustrates, he could deal with an opponent as he pleased. None could escape the network of argument which he wove. Plato inherited from Socrates his intense conviction of the difference between untested opinion and reasoned knowledge, and, starting from the Socratic logic of the definition and simple induction, he worked out in concrete examples the details of the logic of consistency so that all that remained for Aristotle was to codify them and add the formulas of the syllogism. In the prosecution of this task Plato was confronted by certain quibbles about being and not being, the one and the many, the whole and the part, rest and motion, the reality or unreality of abstract ideas, which from one point of view are mere verbal fallacies, from another are problems of psychology and metaphysics. To interpret aright the more metaphysical and abstract dialogues, we must remember that, whether Plato succeeded or failed in solving metaphysical problems which are still debated, he never lost sight of his main object, the removal of the verbal fallacies from the pathway of practical logic. Familiarity with the Aristotelian logic makes this seem a trifle to us. But to accomplish it for the first time was one of the greatest achievements of human genius.

A second fundamental Platonic thought is the postulate that the art of conduct, of individual and social life, ought to be as truly scientific as are the various arts and sciences that deal with material things. To emphasize this thought, Plato makes use of the favorite Socratic comparison or confusion of the virtues and the arts. As there is an art of carpentry or shoemaking known only to him who has mastered it, so 'virtue,' the art of happiness, of conduct, the 'political' or 'royal' art, must be conceived as a specific form of knowledge demanding a special training in its possessor. To the end or aim of the 'royal art' all partial and particular ends would be subordinated—it would be an 'idea of good' in which all particular goods, virtues, and utilities have their ground. Many of the minor dialogues illustrate the inability of the average disputant to apprehend any such larger end, or to define particular virtues and ends in relation to it. Others refute the pretensions of the sophists, rhetoricians, and politicians who claim to teach or practice the art of life and government, but in fact teach only the opinions of the multitude—the humors of the many-headed beast, or

the knack of persuasive speech, or the tricks by which the politician seizes the helm of the ship of state, though he has never learned to steer. Even the few virtuous and judicious statesmen of whom Athens boasts are guided not by knowledge, but by right opinion or happy instinct, which, in the corruption of the existing social order and the absence of all systematic and effective teaching of 'virtue,' must be said to come to them by grace divine (*Meno*).

The *Republic* contains the positive and constructive application of these ideas. There Plato expounds his ideal of a city in which the end of government is not the domination of a faction, nor the multiplication of wealth, nor doing as one likes, but the virtue and consequently the true happiness of the individual citizen, and the order and harmony of the whole. The chief means to this end is justice—the division of labor generalized to mean the proper distribution of function among the three faculties of the soul, the appetites and desires, the emotions and passions, and the ruling reason, and answering to this the severe limitation to their proper work of the corresponding groups of the population—the industrial, the military, and the governing classes—determined by birth only in so far as birth is found to involve natural aptitude. The rulers, the embodied reason of the State, are selected by severe tests from the warriors. Absolute disinterestedness is secured by forbidding them to hold private property and by the paradoxical community of wives and offspring. In order to master the 'political art,' they must supplement the ordinary education in music and gymnastics by a prolonged discipline in mathematics, astronomy, and dialectic, which, as Plato expresses it in a poetical figure, the source of much later mysticism, will enable them to apprehend the 'idea of good,' the cause of light and truth and being in the intelligible world, as the sun is in the world of matter. In the *Republic*, as everywhere, the logical skeleton of Plato's ethical and political theory is clothed with an eloquence nobly employed in the assertion of the ideal aims of life as against base, sensuous, and sordid views of happiness and success. And many readers who care nothing for the abstract logic of Plato's ethical philosophy will be charmed or inspired by the preacher and prophet—his impassioned faith in the moral order of the world, his denunciation of materialistic, sensationist, and hedonistic philosophies, his affirmation in poetical myth and allegory of the hope of immortality and the inevitableness of the judgment of God.

Space fails to speak further of these things; of the vague but devout theism which, without breaking formally with the established polytheism, Plato everywhere professes; of the sage and serious doctrine of Platonic love set forth in the *Phædrus* and *Symposium*, whereby sensuous passion is made the prefigurement and symbol of spiritual exaltation and of all aspirations toward the good, the true, and the beautiful; of the fantastic poetical physics of the *Timæus* with its startling glimpses of the latest truths of science; of the puritanic banishment of Homer from the ideal State, in strange and pathetic contradiction to the poetical fervor of Plato's own temperament and his theory of the divine inspiration of poesy; of countless other things that secure Plato his place not only in the litera-

ture of philosophy, but in that of religion, mysticism, poetry, and æsthetic criticism.

But a word must be said of the theory of ideas with which most expositors of Plato begin and which might be made the centre of the Platonic philosophy. Taken literally, it is the assertion of the astounding paradox that reality belongs not to the individual thing, this book, this tree, this man, but to the general idea of book, tree, or man. The individual things are but the fleeting, perishable copies of the Form or Idea which abides in changeless unity forever, and is the sole object of real knowledge. Primarily, this is merely a paradoxical logic of general terms, which, employed with Plato's unflinching consistency, serves as well as the reverse mode of speech that alone seems reasonable to us. In the second place, it is a manifestation of the plasticity of the Greek imagination which in Plato, as in the mythology and on the stage of Aristophanes, refuses to deal with ideas as algebraic counters, but since they are real forces in thought, life, and speech, treats them as veritable things and persons. In the third place, it is a metaphysical doctrine with regard to the *noumenon* or reality behind the veil of sense which all philosophies that acknowledge an absolute, whether in being or cognition, are compelled to assume. Only those who are willing to affirm that sense is all can consistently condemn as absurd Plato's assertion that ultimate realities are more akin to our ideas than to our sensations and perceptions. Many passages show that Plato saw, as clearly as his modern critics see, the conflict of this doctrine with common sense. But metaphysics is not common sense. The ideas were the only alternative, he thought, to the philosophy of Heraclitus that all things are in perpetual flux, which Plato interpreted to mean, in modern phrase, that reality is merely 'the permanent possibility of sensation.' It is because he would not accept this doctrine that Plato clung to the ideas; not, as we are so often told, because in the infancy of human thought he did not 'understand' the processes of generalization and abstraction.

Associated with the theory of ideas is the poetical doctrine of reminiscence or recollection. The soul has beheld the ideas in a previous stage of existence. "Our birth," as Wordsworth says, "is but a sleep and a forgetting." Learning, experience, is the re-collection of the ideas through the suggestions and association of their imperfect copies in this world. We have never seen two things absolutely equal, but we recollect the idea and ideal of pure equality from the proximate equals of experience. Mathematical truths can be elicited from an uneducated man by skillful questioning (*Meno*). The idea of beauty alone has a not wholly inadequate embodiment on earth. Hence the peculiar ecstasy of the thrill which the aspect of beauty stirs in the lover. It awakens immortal memories of the soul's beatific vision of the idea.

Plato's writings exercised an inestimable influence on Aristotle, the Stoics, Cicero, Plutarch, the Neo-Platonists, the Christian Fathers, the earlier scholastics, the philosophy and poetry of the Renaissance in Italy and England, and on the nineteenth-century revival of historical and philosophical studies in Germany. His influence is rather increasing than diminishing in the higher literature and scholarship of our own time. Nor is it likely soon to wane. To borrow his own

half mystical imagery, he purges the eye of the soul, that it may discern spiritual truth, and converts it from the observation of the transient shadows of the fire-lit cave, to the contemplation *sub specie æternitatis* of the abiding forms of pure being illumined by the idea of good.

BIBLIOGRAPHY. The best critical edition of the text is that of Schanz, still incomplete. Good and convenient texts abound—in the Teubner Series, in the Didot Bibliotheca, and that now in course of publication at Oxford. The chief complete annotated edition is that of Stallbaum with Latin notes, parts of which have been re-edited by other scholars. Campbell's *Theætetus*, *Sophistes*, and *Politicus*, Jowett and Campbell's *Republic*, Archer Hind's *Phædo* and *Timæus*, and Bury's *Philebus* are well known. School and college editions of the *Apology* and *Crito*, the *Protagoras*, *Georgias*, *Meno*, and *Euthyphro* abound. Jowett's translation (3d ed.) supersedes all others for English readers. Grote's four volumes of summary and comment cite the literature down to the year 1866. The volume on Plato in the last edition of Zeller's *History of Greek Philosophy* is the fullest scholarly treatment of the whole subject. Professor Ritchie's *Plato* (New York, 1902) is a readable sketch. For the right understanding of Plato, however, the best guide is Mill's review of Grote (*Dissertations and Discussions*, vol. iv., p. 227), supplemented where unsympathetic by Pater's *Plato and Platonism* (New York, 1893), and Emerson's essay in *Representative Men*.

PLATO'DA. See PLATYHELMINTHES.

PLATOFF, plä'töf, MATVEI IVANOVITCH, Count (1751-1818). A Russian general and hetman of the Cossacks of the Don. He was born on the banks of the Don, August 17 (6), 1751, and was of Greek descent. In 1765 he entered the Russian Army and distinguished himself in the wars against Turkey and France, so that in 1801 he was appointed by Alexander I. hetman of the Cossacks, and lieutenant-general in the Russian Army. As commander of the Russian irregular cavalry, he took a prominent part in the further wars with France and Turkey. In the War of 1812, after the French had evacuated Moscow, Platoff hung upon their rear with the utmost pertinacity, wearying them by incessant attacks, cutting off straggling parties, capturing their convoys of provisions, and keeping them in a state of continual terror and apprehension. French historians state that Napoleon's army suffered more loss from the attacks of Platoff's Cossacks than from privation and exhaustion. After crossing the Prussian frontier he occupied Marienwerder and other cities. On May 28, 1813, he defeated Lefebvre at Altenburg. After the defeat of the French at Leipzig he inflicted great loss upon them in their retreat, and subsequently gained a victory over them at Laon. His undisciplined bands committed great depredations everywhere, but Platoff was loaded with honors by the monarchs who were warring against France. Alexander made him a count in 1812.

PLATONIC BODIES. See POLYHEDRON.

PLATO OF TIVOLI, or TIBURTINUS (c.1120). A translator of Arabic mathematical manuscripts. He is known chiefly for his translation of the trigonometry and astronomy of Al Battani. Among his contemporaries are Gerard of Cremona, Athelard of Bath, and John of Seville,

likewise known for their translations of Arabic mathematical manuscripts into Latin.

PLATOON (Fr. *peloton*, platoon, tennis-ball, diminutive of *pelote*, OF. *pelote*, *pelotte*, ball, from ML. *pilota*, diminutive of Lat. *pila*, ball). A term formerly used to designate a body of troops who fired together. In its modern sense, in the United States Army, it is practically half a company of infantry. The company is divided into two platoons, and each platoon into two sections. Two or three squads constitute a section, the squad consisting of four files, a corporal and seven privates, the corporal being the squad leader. The first lieutenant is in command of the first platoon, and the second lieutenant of the second platoon. The term is obsolete in the British Army, that of *half-company* being substituted.

PLATT, CHARLES ADAMS (1861—). An American landscape architect, painter, and etcher. He was born in New York City, and studied at the schools of the National Academy of Design and the Art Students' League from 1878 to 1880. In 1882 he went to Paris, where he worked for four years under Boulanger and Lefebvre, and exhibited at the Salon. His best paintings include "Clouds," which was awarded the Webb prize offered by the Society of American Artists, and "Snow," awarded a bronze medal at the Paris Exposition of 1900. He also received a medal at the Buffalo Exposition of 1901. As an etcher he produced some good work, selecting his subjects principally from the lives of Dutch fishermen and from scenes in Holland.

PLATT, ORVILLE HITCHCOCK (1827—). An American legislator and political leader, born at Washington, Conn. He received an academic education, studied law, and was admitted to the bar in 1849. He practiced law at Meriden, was clerk of the State Senate in 1855-56, and the next year became Secretary of State of Connecticut. He was elected as a Republican to the State Senate in 1861 and to the State House of Representatives in 1864 and 1869, the latter year being chosen Speaker. He succeeded William H. Barnum, Democrat, in the United States Senate on March 18, 1879, and was reelected in 1885, 1891, 1897, and 1903. On February 25, 1901, he reported from the Committee on Relations with Cuba an amendment to the Army Appropriation Bill which required the new Republic to place itself under the protection of the United States. This amendment was accepted by Cuba and was made part of its organic law.

PLATT, THOMAS COLLIER (1833—). An American political leader. He was born at Owego, N. Y.; studied at the Owego Academy, and was a member of the class of 1853 in Yale College, but withdrew in his junior year on account of ill health. He then went into business, became president of the Tioga National Bank, and invested largely in lumbering in Michigan. He was clerk of Tioga County in 1859-61, and a member of Congress from 1872 to 1876. In 1879 he was made secretary and director of the United States Express Company, and in 1880 became its president. He also acted as president of the Southern Central and other railways. In 1880 he was appointed a quarantine commissioner at the port of New York. In 1881 he was elected United States Senator, but within a few months both he

and Senator Roscoe Conkling, his colleague from New York, resigned because President Garfield did not defer sufficiently to their wishes in making appointments in New York. The immediate occasion of their resignation was the appointment by Garfield of W. H. Robertson as collector of the port of New York City. (See CONKLING, ROSCOE; and ROBERTSON, W. H.) In an appeal to the Legislature for reelection they were both defeated. Platt eventually gained virtual control of the Republican Party in New York and was again elected to the Senate both in 1897 and in 1903. He has been a delegate to all Republican national conventions since 1876 as well as a member of the National Republican Committee.

PLATTDEUTSCH, plät'doich, or Low SAXON. The language spoken in Northern Germany from the border of Holland to the frontier of Lithuania. It is distinguished on the one hand from Low Franconian, which includes the language of Holland, Dutch proper (see DUTCH LANGUAGE), and, on the other hand, from Middle and Upper German, which are grouped together under the name High German. In common with other Low German languages, Plattdeutsch is distinguished from High German by the fact that its surd mutes have not passed through the second or High German sound-shifting. (See GRIMM'S LAW.) There is, however, no definite line of demarcation, some of the Middle German dialects not having shifted *p* and *t*. The best criterion of distinction is the so-called *ich-line* which starts on the Belgian border south of Limburg and runs in a northeasterly direction, crossing the Rhine at Benrath (between Düsseldorf and Cologne), the Elbe south of Magdeburg, the Oder just above Frankfort, and finally reaches the Slavic frontier in the Province of Posen near Birnbaum. To the north of this line the first personal pronoun has the form *ik*, to the south *ich*. Within its district Plattdeutsch is generally spoken by the lower classes, while High German is the language of the school and pulpit, and as a rule of the educated classes.

Plattdeutsch is not a homogeneous language, but consists of a number of different dialects which may be divided into two main groups: (1) Northeast Saxon, in Oldenburg, Bremen, Hamburg, Hanover, Brunswick, Holstein, Mecklenburg, Brandenburg, Pomerania, and East Prussia; (2) Westphalian, in Westphalia and the Principality of Waldeck. During the nineteenth century the dialect of Mecklenburg acquired especial prominence through the writings of Fritz Reuter.

Historically Low Saxon is divided into (1) Old Saxon or Old Low German, extending from the ninth to the twelfth century; (2) Middle Low Saxon, from the twelfth to the end of the sixteenth century; (3) Modern Low Saxon, Plattdeutsch, or Modern Low German, from 1600 to the present time.

In the Old Saxon period the principal literary monument is the *Heliand* (q.v.), a religious epic of nearly 6000 lines in alliterative verse, written about 830 at the request of Louis the Pious. Several fragments of a versification of the first chapters of the Book of Genesis, an interlinear version of the Psalms, and various other smaller fragments of a religious character have been preserved, besides a number of glosses and proper names. Old Saxon may also lay partial claim to the *Hildebrand's Lay*, the most famous of all

old German ballads, as it is written partly in this dialect.

The most noted prose document of the Middle Low Saxon is the *Sachsenspiegel*, a compilation of Saxon common law, made by Eyke von Repchow between 1224 and 1230, and which became the model for law books in other parts of Germany. From 1350 through the fifteenth century there is an extensive Low German literature, which is mainly religious in character, consisting largely of legends of the Church and collections of hymns. Among secular poems may be mentioned *Reincke der Vos* (Lübeck, 1498) and *Flore und Blankflur*. About the middle of the seventeenth century Low Saxon ceased to be a literary language, the last Low Saxon Bible appearing at Goslar in 1621. In modern times what little literature has appeared has been of a decidedly dialectical character. Especially prominent are Fritz Reuter (q.v.), best known for his humorous novel *Ut mine Stromtid* and the poem *Hanne Nüte*, and Klaus Groth (q.v.), a writer of lyric poems, as the *Guickborn*.

PLATTE, or **NEBRASKA**. The principal river in Nebraska, and one of the largest tributaries of the Missouri. It is formed by the North and South Platte Rivers, which rise in the Rocky Mountains, and unite in Lincoln County, Neb. (Map: Nebraska, G 2). The North Platte has its source in northern Colorado, flows north into Wyoming, and then southeast into Nebraska. The South Platte rises in central Colorado, and flows northeastward to the junction. From there the main river flows eastward in two large curves through a broad and fertile alluvial bottom, entering the Missouri at Plattsmouth, 17 miles south of Omaha. Its total length, including the North Platte, is about 900 miles, but, although the main river is more than half a mile wide it is quite too shallow to be suited for navigation.

The South Platte is extensively used for irrigat-ing purposes.

PLATTENSEE, plät'ten-zâ. The largest lake of Hungary. See **BALATON, LAKE**.

PLATTER, plät'tër, THOMAS (1499-1582). A Swiss printer, scholar, and educator, born at Grenchen, near Visp. He was a goat herder in his boyhood; then, getting a little learning from a priest, saw Germany as a traveling scholar; and, returning to Switzerland, studied under Myconius at Zurich. His devotion to Zwingli spurred him to the study of Greek and Hebrew. At Basel he learned the rope-maker's trade, and worked at it at the same time that he was professor of Hebrew. His greatest claim to fame rests on his autobiography, written at his son's request in fourteen days, when the father was seventy-three. It gives a remarkable picture of the times, which is supplemented by that of his son, **FELIX PLATTER** (1536-1614), a doctor of medicine and instructor at Basel. The two biographies are edited by Heman (Gütersloh, 1882). Consult Boos, *Thomas und Felix Platter* (Leipzig, 1878).

PLATTEVILLE. A city in Grant County, Wis., 135 miles west by south of Milwaukee; on the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern railroads (Map: Wisconsin, C 6). It is the seat of a State normal school with a library of 5700 volumes. The surrounding country is largely agricultural, but possesses important lead-mining interests. In the city are manufactories of wagons, creamery products, beer, cigars, etc. The water-works are owned by the municipality. Platteville was settled in 1827. Population, in 1890, 2740; in 1900, 3340.

PLATTSBURG. A village and the county-seat of Clinton County, N. Y., 167 miles north by east of Albany; on Lake Champlain, at the mouth of the Saranac River, and on the Delaware and Hudson and the Chateaugay railroads (Map: New York, G 1). It is picturesquely situated on Cumberland Bay, which affords a fine harbor, and is an attractive resort, as well as the centre of a large territory popular in summer. Plattsburg is the seat of a State Normal and Training School, and has a public library and four other libraries. The Plattsburg Barracks (q.v.) are among the largest in the United States. There are also to be mentioned the Federal Government building, the court-house and jail, and homes for aged women and the friendless. The Catholic Summer School of America (q.v.) convenes at Cliff Haven, two miles south of the village. Plattsburg is a port of entry for the Champlain customs district, the trade of which in 1901 comprised exports valued at \$7,714,000 and imports to the amount of \$3,763,000. It controls extensive lumber interests, and among its industrial establishments are lumber mills, wood pulp mills, foundries and machine shops, flouring and woolen mills, a manufactory of sewing machines, etc. The various industries, in the census year of 1900, represented a total capital of \$2,210,000, and had products valued at \$1,455,000. The water-works are owned and operated by the municipality. Population, in 1890, 7010; in 1900, 8434.

Plattsburg was settled in 1784 by a company from Poughkeepsie and Long Island headed by Zephaniah Platt and was incorporated in the fol-

lowing year. Off Valeour Island, near by, on October 11, 1776, occurred the first naval battle ever fought between British and American fleets, Benedict Arnold (q.v.) being in command of the latter and Sir Guy Carleton of the former. Arnold was defeated. During the War of 1812 Plattsburg was the headquarters of the United States forces on the northern frontier, and on September 11, 1814, in Plattsburg Bay Commodore McDonough defeated a British fleet in the famous battle of Lake Champlain (see CHAMPLAIN), while on the land General Macomb repulsed a superior British force. In 1849 and again in 1867 Plattsburg suffered severely from fire, the greater part of the business portion being destroyed each time. Consult Palmer, *History of Plattsburgh* (Plattsburgh, 1877).

PLATTSBURG BARRACKS. A United States military post, established in 1838 and occupying a reservation of 679 acres in extent, on the west side of Lake Champlain, one mile from Plattsburg, N. Y., which is the post-office and telegraph station. The post has quarters for a regiment of infantry. United States troops were first stationed on the ground in 1812.

PLATTSMOUTH. A city and the county-seat of Cass County, Neb., 21 miles south of Omaha; on the Missouri River at the mouth of the Platte, and on the Missouri Pacific and the Chicago, Burlington and Quincy railroads (Map: Nebraska, J 2). It has a public library; and among its finest buildings are the court-house, opera house, and the high school. The industrial establishments include the Burlington Railroad shops, brick and terra-cotta works, and cigar factories. There is considerable trade with the tributary region, which is interested mainly in agriculture and stock-raising. Platts-mouth is governed by a mayor, elected biennially, and a unicameral council. Population, in 1890, 8392; in 1900, 4964.

PLATYCERAS, plá-tis'ér-as (Neo-Lat., from Gk. πλατύς, *platys*, flat, broad + κέρα, *keras*, horn). A genus of fossil snail shells of the gastropod family Capulidæ, found in rocks of Upper Cambrian to Triassic age. They are shaped somewhat like a liberty cap with the apex of the shell enrolled in a close spiral of small size and with the outer or body whorl of the shell rapidly enlarging to an irregularly expanded aperture. *Platyceras* is most abundant in the Niagara, the Devonian, and the Subcarboniferous formations, and the genus is more or less an index fossil of Devonian age. The genus *Orthonychia* includes straight or slightly rounded platycerid shells of Silurian to Carboniferous age. Consult: Keyes, "The *Platyceras* Group of Paleozoic Gastropods," in *American Geologist*, vol. x. (Minneapolis, 1892); "Attachment of *Platyceras* to Palæocerinoidea, and Its Effect in Modifying the Form of the Shell," in *Proceedings of the American Philosophical Society*, vol. xxv. (Philadelphia, 1888).

PLATYHELMINTHES (Neo-Lat. nom. pl., from Gk. πλατύς, *platys*, flat, broad + ἕλμινς, *helmins*, worm), or **PLATODA**. A phylum of invertebrate animals (flatworms), easily recognized by the absence of a body-cavity and anus. There is no blood system, the results of digestion being carried to the different parts of the body by branches of the intestine. The body is flattened dorso-ventrally, so that it is often thin and leaf-like. The surface is covered with cilia in most

of the free-living forms, but in parasitic forms is usually smooth and somewhat chitinous. The muscular system is well developed and remarkably complex, so that almost any sort of movements are possible to these worms. The digestive system is usually very well developed and highly varied, but in some forms is wholly wanting. The nervous system consists of a ganglion above the œsophagus, and two lateral nerve cords, connected by transverse commissures. Other longitudinal trunks are sometimes present, and rarely the transverse commissures are wanting. A very characteristic and remarkable set of fine tubes ramifies through the body and apparently serves as an excretory system. Sense organs of various kinds occur in the free-living forms, but are usually wanting in those which are parasitic. Occupying a large part of the body, and often nearly the whole space inside the skin, are the reproductive organs, and the fertilization of the egg is in almost all cases internal. The *Turbellaria* are hermaphroditic. The eggs are very numerous, provided with considerable yolk and covered by a shell, but some planarians multiply by fission, and when cut in pieces each piece may eventually become a well-formed planarian. The young undergo a metamorphosis and development sometimes very complex. The phylum is usually divided into three classes: (1) *Turbellaria*, free-living flatworms, with the surface ciliated; (2) *Trematoda*, parasitic, usually leaf-like, flatworms having a well-developed digestive system; (3) *Cestoda*, the tapeworms, usually elongated, jointed, and without a digestive system. Consult Parker and Haswell, *Text-book of Zoölogy* (New York, 1897). See **FLATWORM**; **CESTODA**; **TREMATODA**.

PLATYRHINI. The American monkeys. See **MONKEY**.

PLATYSTROPHIA (Neo-Lat. nom. pl., from Gk. πλατύς, *platys*, broad, flat + στρόφιον, *strophion*, band). A hinged brachiopod very abundant and eminently characteristic of the Middle Ordovician formations, of which it is a well-known index fossil. Its shell is transversely elongated, with a long straight hinge line and low hinge areas. The convex valves are of about equal size, and their surfaces are marked by a number of strong angular radiating folds. Two species, *Platystrophia lynx* and *bifurcata*, with numerous varieties, are common in the Trenton and Cincinnati groups of North America, and in equivalent strata of Europe and elsewhere. This genus was originally included under *Orthis*.

PLAUVEN, plou'én. A town of Saxony, Germany, on the White Elster, 21 miles southwest of Zwickau (Map: Germany, E 3). Most of its public buildings are modern. Among the most noteworthy are the castle, dating from the seventeenth century, the Rathaus, and the theatre. The educational institutions include a gymnasium, a realschule, a seminary for teachers, and a number of special schools. Plauen occupies a prominent place among the manufacturing cities of Germany, being the chief centre for the production of white cotton goods, namely lace curtains, muslin, cambric, mull, batiste, various embroidered goods, etc. It also manufactures machinery, safes, pianos, paper, beer, etc. The population of the town increased from 47,007 in 1890 to 73,891 in 1900. The inhabitants are principally Protestants. The manufacturing of white goods was

introduced at the end of the sixteenth century from Switzerland.

PLAUTIA, plā'shī-ā (or **PLOTIA**) **GENS**. A Roman plebeian tribe, several members of which became consuls. It embraced the family names Hypsæus, Proculus, Silvanus, Venno, and Venox.

PLAUVTUS, **TITUS MACCIUS**. The greatest comic poet of ancient Rome. He was born c.254 B.C. at Sarsina, a village of Umbria. It is probable that he came to Rome while still a youth, and there acquired a complete mastery of the Latin language in its most idiomatic form, as well as an extensive familiarity with Greek literature. It is uncertain whether he ever obtained the Roman franchise. His first employment was with the actors, in whose service he saved an amount of money sufficient to enable him to leave Rome and commence business on his own account. What the nature of this business was, or where he carried it on, we are not informed; we know, however, that he failed in it, and returned to Rome, where he had to earn his livelihood in the service of a baker, with whom he was engaged in turning a hand-mill. At this time—a few years before the outbreak of the second Punic War—he was probably about 30 years of age; and while employed in his humble occupation, he composed three plays, which he sold to the managers of the public games. The proceeds enabled him to leave the mill and turn his hand to more congenial work. The commencement of his literary career may, therefore, be fixed c. 224 B.C., from which date he continued to produce comedies with wonderful fertility, till 184, when he died in his seventieth year.

Of his numerous plays—130 bore his name in the last century of the Republic—only 20 have come down to us. Many of them, however, were regarded as spurious by the Roman critics, among whom Varro (in his treatise *Quæstiones Plautinæ*, cited by Gellius) limits the genuine comedies of the poet to twenty-one. With the exception of the twenty-first, these Varronian comedies are the same as those we now possess. Their titles, arranged (with the exception of the *Bacchides*) in alphabetical order, are as follows: (1) *Amphitryo*, (2) *Asinaria*, (3) *Aulularia*, (4) *Captivi*, (5) *Curculio*, (6) *Casina*, (7) *Cistellaria*, (8) *Epidicus*, (9) *Bacchides*, (10) *Mostellaria*, (11) *Menæchmi*, (12) *Miles*, (13) *Mercator*, (14) *Pseudolus*, (15) *Pænulus*, (16) *Persa*, (17) *Rudens*, (18) *Stichus*, (19) *Trinummus*, (20) *Truculentus*, (21) *Vidularia*. As a comic writer, Plautus enjoyed immense popularity among the Romans and held possession of the stage down to the time of Diocletian. The vivacity, the humor, and the rapid action of his plays, as well as his skill in constructing plots, commanded the admiration of the educated no less than of the unlettered Romans; while the fact that he was a national poet prepossessed his audiences in his favor. Although he laid the Greek comic drama under heavy contributions, and 'adapted' the plots of Menander, Diphilus, and Philemon with all the license of a modern playwright, he always preserved the style and character native to the Romans and reproduced the life and intellectual tone of the people in a way that at once conciliated their sympathies. The admiration in which he was held by his contemporaries descended to Cicero and Saint Jerome; while he has

found imitators in Shakespeare, Molière, Dryden, Addison, and Lessing, and translators in most European countries. The best complete translation of his works into English is that by Thornton and Warner (5 vols., 1767-74); there is another by Riley (London, 1880), and a partial translation in the original meter, by Sugden (London, 1893). Unfortunately the text of the extant plays is in such a very corrupt state, so defective from lacune, and so filled with interpolations, that much yet remains to be done by the grammarian and the commentator before they can be read with full appreciation or comfort. Ritsehl and his disciples gave the text its first exhaustive recension, on which are based the modern editions, such as those of Ussing (5 vols., Copenhagen, 1875-86) and Goetz and Schoell (3 vols., Leipzig, 1893-96). Among the many good editions of separate plays, with commentary, may be mentioned those of Brix, Lorenz, Morris, Palmer, and Tyrrell. Consult Sellar, *Roman Poets of the Republic* (Oxford, 1881).

PLAYA, plā'yā (Sp., shore). The name given to mud-plains formed by the deposition of silt in temporary lakes. In arid regions, such as the Great Basin, water collects in the valleys during the dry season forming shallow lakes, which shrink or entirely disappear with the recurrence of dry weather. The sediment left by evaporation consists of finely divided rock-débris impregnated with salt and becomes very hard under the sun's heat. The Black Rock Desert, in northwestern Utah, is an example of a playa.

PLAYERS' CLUB, **THE**. A social club in New York City composed of men identified with American art, literature, painting, sculpture, architecture, the drama, etc., as well as prominent bankers and lawyers. Its creation was due in a great measure to the liberality of the tragedian Edwin Booth (q.v.), to whom the club is indebted for its handsome club house at 16 Gramercy Park, New York City. It was purchased by Mr. Booth for \$75,000, and entirely remodeled. The work was completed in 1888, and on December 31st of that year it was formally presented, furnished and equipped for all the needs of club life. The club had been organized after the purchase of the building. Its affairs are managed by a board of nine directors, who must be identified with literature and the drama, and at least five of the body must be actors, dramatic writers, or theatrical managers.

PLAYFAIR, **JOHN** (1748-1819). An English mathematician and geologist, born at Benvie. He was taught by his father until he was 14 years of age, when he was sent to Saint Andrews, where he made rapid progress, especially in mathematics and natural philosophy, graduating in 1765. He entered the ministry in 1770, but still devoted his leisure time to mathematical studies, and in 1779 he contributed to the *Transactions of the Royal Society* a paper "On the Arithmetic of Impossible Quantities." In 1785 he became professor of mathematics, jointly with Dr. Adam Ferguson, in the University of Edinburgh. He became secretary of the physical class in the Edinburgh Royal Society in 1789, and later general secretary, which post he held till his death. In 1805 he exchanged the chair of mathematics for that of natural philosophy. In 1807 he became a fellow of the Royal Society. A few years before his death he traveled through France,

Switzerland, and Italy, for the purpose of studying the geological and mineralogical features of these countries. From 1804 onward he was a frequent contributor to the *Edinburgh Review*. Among the subjects reviewed are "Mudge's Trigonometrical Survey" (1805); "Mechain and Delambre, Base du système métrique décimale" (1808); "Le Compte rendu par l'Institut de France" (1809); "Lambton's Indian Survey" (1813); "Laplace, Essai philosophique sur les probabilités" (1814); "Baron de Zach, Attraction des montagnes" (1816); "Kater on the Pendulum" (1818). All of these were reprinted in the fourth volume of the collected edition of his works, edited by James G. Playfair (4 vols., 1822). He also contributed several articles to the *Encyclopædia Britannica*. For the *Transactions* of the Royal Society of Edinburgh he wrote among other memoirs: "On the Origin and Investigations of Porisms" (1794); "On the Trigonometry of the Brahmans" (1798). He also edited Euclid's *Elements* (1795), and wrote *Outlines of Natural Philosophy* (2 vols., 1812-16), and *Illustrations of the Huttonian Theory of the Earth*.

PLAYFAIR, LYON, first Baron PLAYFAIR (1818-98). A British scientist and statesman, born at Chunar, in Bengal. He was educated at Saint Andrews and at Glasgow, where he took a course in chemistry. After studying under the celebrated German chemist Liebig, he was in 1843 appointed honorary professor of chemistry at the Manchester Royal Institution. In 1858 he was appointed to the chair of chemistry in Edinburgh University. In 1868 he was returned to Parliament as a Liberal from the Scotch universities, and in 1873 he was appointed postmaster-general and became a privy councillor. In 1892 he was raised to the peerage as Baron Playfair of Saint Andrews, and was appointed a lord in waiting. He wrote *Science in Its Relation to Labor* (1853); *On Primary and Technical Education* (1870); and *Science in Relation to the Public Weal* (1885).

PLAYING CARDS. See CARDS.

PLAYS. See DRAMA.

PLEA (OF. *plait, plaid, play*, Fr. *plaid*, from Lat. *placitum*, decree, suit, plea, opinion, from *placere*, to please). In common-law pleading, the defendant's answer or defense, consisting either of a denial of the facts alleged in the declaration, or a confession that they are true and a statement of new facts by which their legal effect is avoided, or of facts tending to defeat the action itself. A *plea* is distinguished from a *demurrer* in that the latter admits the facts alleged in the declaration, but denies their sufficiency in law to constitute a cause of action; whereas a *plea* raises only a question of fact in the manner indicated in the above definition.

Pleas are usually classed as 'peremptory' and 'dilatory,' according to their purposes and nature. A peremptory plea is one which brings in issue the merits of the controversy, either by denying absolutely the facts alleged in the declaration, when it is known as a 'plea in bar,' or by confessing that the facts alleged by the plaintiff are true, and setting forth new facts, which, if true, will defeat the alleged cause of action. The latter

is known as a plea in confession and avoidance. A dilatory plea is one which attacks the action itself because of some defect in pleading or practice, and therefore does not involve the merits. See NONSUIT.

In criminal cases only pleas of 'guilty' or 'not guilty' are allowed. In equity pleading a special answer of the defendant attacking the particular action is also called a plea. It differs from a demurrer in equity in that it attacks something not apparent on the face of the bill, and it does not put in issue the merits of the action.

In England, where common-law pleading has been abolished, the Judicature Acts (q.v.) provide that the defendant's answer shall be known as the 'statement of defense,' and this is analogous to a plea. The term 'Pleas of the Crown' was formerly used to designate criminal prosecutions in the name of the sovereign. In the United States wherever code pleading prevails the term plea is no longer employed, a defense of fact being presented by an answer. However, the divisions of pleas are often referred to by courts and attorneys as descriptive of the nature of a defense set forth by an answer. See PLEADING.

PLEADING (from *plead*, from OF., Fr. *plaid-er*, from OF. *plait, plaid, play*, Fr. *plaid, plea*). As a generic term, the written allegation of facts upon which a party to any legal proceeding founds his claim or demand or his answer or defense thereto. Used in a broader sense, the term signifies the system of legal rules and principles applicable to the written pleadings in a legal proceeding.

Pleading is only one of the successive steps in a proceeding at law by which one party asserts or enforces his rights against another, all together being comprehended by the term procedure (q.v.). Originally the pleadings in an action at common law were oral, as is evidenced by many peculiarities of the common-law procedure of a later date; but as early as the reign of Edward III. we find that the pleadings were in writing and usually in Latin.

Pleading at law, however, ultimately developed into a system of highly technical and formal rules requiring the greatest precision in their application, and often by their very formality and rigidity defeating rather than aiding justice. Although remedial statutes were passed as early as the reign of Elizabeth, no attempt at a general reformation of the system was made until 4 William IV., c. 42, in 1834. At a later date in the United States various forms of statutory or code pleadings were adopted.

The principles upon which any system of pleading are necessarily based will, perhaps, be best understood by referring briefly to the more essential elements of the common-law system. The primary object of the pleadings in an action at common law was to raise a single issue or dispute upon either a point of law or of fact. In the former case a question was raised for decision by the court, usually after argument upon the question of law involved and submission of briefs by opposing counsel. In the latter, a question was raised for decision by the jury after hearing evidence tending on the one side to prove and on the other to disprove the fact in dispute. And upon the decision of the court or a verdict of the jury final judgment was entered determining the rights of the parties to the controversy.

The first step toward accomplishing the object

of pleading after service of summons or mandate of the court upon the defendant was the filing of the declaration (known in modern practice as the complaint) in court. In the declaration the facts were required to be stated according to their legal effect only, and it was not permissible to set out the evidence on which the plaintiff relied. Owing to the tendency of the early lawyers to adopt fixed forms of statement and to their adherence to precedent, the declaration was required to conform to one of a limited number of rigid forms, and if a plaintiff could not adapt the state of facts upon which he based his right to recover to one of these forms, he was without remedy. See FORMS OF ACTION.

After the plaintiff had filed his declaration it was then incumbent upon the defendant to make some statement of his defense; otherwise, after a certain period, judgment would be taken against him by default. If the defendant conceived that the declaration, if taken as true, did not show sufficient grounds to justify the plaintiff's recovery (or, as it was said, did not state a cause of action), he could submit the question of its sufficiency to the court as a matter of law by filing a demurrer to the declaration. (See DEMURRER.) If, however, the defendant wished to deny any of the allegations contained in the declaration, he might do so by filing a formal denial, his pleading in that case being known as a plea by way of traverse. An issue of fact was thus raised for decision by the jury.

It might happen, however, that the defendant, while admitting the truth of all the allegations in the declaration, and admitting that it was legally sufficient, relied upon the existence of new or other facts sufficient to excuse him from the liability charged in the declaration, in which case his plea took the form of a confession and avoidance (q.v.). The plaintiff might then plead, setting up either a demurrer to the plea or a denial with the effect already described; or he in turn might plead by way of confession and avoidance and thus cast upon the defendant the burden of pleading again. In every case the pleadings were thus continued until a single issue of law or fact was raised, and the determination of that issue determined the rights of the parties to the litigation. Any plea of a defendant, such as has been described, setting up some matter of defense to the plaintiff's claim was known as a plea in bar or as a plea to the merits. It might happen, however, that the defendant wished to insist upon some matter which, though not a complete defense to the plaintiff's claim, was sufficient to show that the action was brought in an improper manner, as that the plaintiff was a married woman and had not joined her husband as plaintiff, or that the court had no jurisdiction, or that the defendant was not properly named. Such a plea was known as a plea in abeyance. The effect of a plea in abeyance, if successful, was to cause a dismissal of the plaintiff's action without prejudice to a second action if properly brought. If unsuccessful the defendant was allowed to plead again to the merits.

The successive pleadings in an action, beginning with the plaintiff's pleading, were named the declaration, plea, replication, rejoinder, sur-rejoinder, rebutter, and sur-rebutter. Although theoretically possible, it was not usual for the proceedings to continue beyond the rebutter or sur-rebutter.

Upon the trial of an issue of fact, as the character of the issue was determined by the pleadings, it necessarily followed that the relevancy of all evidence offered at the trial was also primarily determined by the pleadings. Upon the entry of judgment all the pleadings in the case, together with the judgment constituting the judgment roll, were filed with the clerk of the court, thus constituting a complete permanent record of the case.

Owing to the highly technical and formal nature of the common-law system, the practice grew up of deciding the rights of litigants upon purely formal grounds, and judgment was frequently taken against a party upon demurrer because he had failed to state a perfectly valid claim or defense in the proper form. This was corrected to some extent by the statute of 27 Eliz., c. 5, sec. 1, which provided that no advantage should be taken of defects of form, except by a special demurrer which should state specifically the formal defect objected to. The statute 4 Anne, c. 16, sec. 1, was enacted for more effectively accomplishing this result, and 15 and 16 Vict., c. 76, sec. 50-52, abolished the special demurrer and required all defects of form to be taken advantage of by motion before trial. This is generally the modern practice. The statute of Anne referred to allowed the defendant to plead several pleas to the same declaration, thus breaking down to some extent the principle of singleness of issue. Through laxity of practice also the defendant was allowed in his plea to make use of a general denial, known as the general issue, the effect of which in most actions was ultimately not only to deny all the essential allegations of the declaration, but to allow the defendant at the trial to prove many matters of affirmative defense. An attempt was made by statute, 4 Wm. IV., c. 42, to avoid the confusion and the frequently illogical results of this complicated system by authorizing the judges of the common-law courts to adopt certain rules modifying the common law of pleading as it then existed. These rules, known as the Hilary rules, were promulgated in 1834 and had for their principal object the narrowing of the general issue so as to make it conform more closely to a logical denial of the allegations in the complaint. These rules, however, did not succeed in accomplishing the desired result, and seem only to have added to the confusion into which the subject had fallen. The law was substantially revised by 15 and 16 Vict., c. 76, and modern legislation has been enacted in all of the United States in which the common-law system has been retained.

Following are the more essential changes:

Matters of form are required to be taken advantage of by motion before trial, otherwise they are deemed to have been waived. Singleness of issue is not required, the defendant being allowed to use the general denial and to plead several matters by way of confession and avoidance. In many jurisdictions the number of successive pleadings is limited. Decisions upon demurrers are not necessarily final, the defendant being usually allowed to plead to the merits in case his demurrer is overruled.

Great freedom of amendment is allowed, a party being allowed to correct a defective pleading by amendment on application to the court,

even at the trial of the action, if the rights of his opponent will not be prejudiced by the amendment. There are also many minor changes, the general object being to make the system more simple and just in its application, and to avoid the determination of rights upon purely formal grounds.

PLEADING AT CRIMINAL LAW. At common law pleading in criminal actions was in its essentials substantially like pleading in civil actions, although much less elaborate.

The first pleading was called the indictment (q.v.). To this the accused might interpose a demurrer, as in civil actions, and with like effect, except that if the demurrer were overruled he was allowed to plead to the indictment. All matters tending to show that the accused was not guilty of the offense charged might be shown under the oral plea *not guilty* or the plea *nolo contendere*, which was equivalent to guilty, except that it was not an admission by the defendant which could be used against him in evidence in a civil suit for the same act. After the plea no further pleading was necessary. The plea of abatement or previous conviction or acquittal of the same offense were required to be specifically pleaded as a plea by way of confession and avoidance; and to these the prosecution might demur with the same effect as a demurrer to a plea in abatement in a civil action.

Pleading at criminal law has been subjected to fewer statutory changes than pleading in civil actions. In some States less formality is required than at common law, and final judgment cannot be entered upon purely formal grounds. Formal defects may be cured by amendment, but there can be no amendment to matter of substance in an indictment, otherwise an amended indictment would not satisfy the requirement that the indictment must be found by the grand jury.

EQUITY PLEADING. The system of pleading adopted in equity by the English Court of Chancery was derived partly from the common-law system and partly from the civil-law system as administered by the English ecclesiastical courts.

The important features of the civil-law system which characterize equity pleading were: (a) the absence of the denial or traverse, the rule being that all the allegations in a pleading were deemed to be denied unless expressly admitted by a subsequent pleading, which was exactly the converse of the common-law rule by which all the allegations in a pleading were deemed to be admitted unless expressly denied; and (b) the practice by which a party to the litigation could compel his opponent to testify, or give discovery, as it was called, in advance of argument or trial as to the matters alleged in the first party's pleading.

The plaintiff's pleading in an equity action is called the bill. In effect it is a petition addressed to the court asking that subpoena issue compelling the defendant to answer the bill. Formerly bills in equity were prepared with great formality and were usually composed of nine distinct parts. Of these, however, only four are important in modern practice, and two of these may be dispensed with. The essential parts are the statement of facts and the prayer for relief.

For the purpose of obtaining discovery the plaintiff might state in his bill at great length

the evidence upon which he relied in support of his claim. This was known as the charging part of the bill. He might also ask specific questions founded upon the stating and charging parts of the bill, which he required the defendant to answer. This was known as the interrogatory part of the bill. After the appearance of the defendant, failing which a decree would be taken against him by default, he was required to answer the bill. The answer, which was required to be under oath, might set out at length any matters of defense, however numerous, relied upon by the defendant, but he was required to make discovery or give testimony by answering fully and specifically the charging and interrogatory parts of the bill.

In early times other pleadings might follow the answer as at common law, but ultimately the answer came to be the last substantial pleading, and was followed only by a formal plea always of the same tenor and used only to indicate that the parties were at issue.

In case it became necessary for the plaintiff to meet any of the allegations in the answer, this was accomplished by amendment. Upon the testimony taken before a master in chancery, and upon the answer, which was deemed to be not only a pleading, but in effect evidence introduced by the plaintiff, the decision and final decree of the Court of Chancery were based.

Equity pleading borrowed from the common law the use of the demurrer and the plea, with practically the same effect.

In the courts of equity of the United States, which, in accordance with the Constitution and statutes of the United States, are distinct from the courts of common law, the same system of pleading is used as in the English Court of Chancery as it has here been outlined. The pleading in the United States courts is, however, subject to modification by rules of court. The same system of equity pleading also obtains in those States in which the distinction between courts of equity and of law has been maintained, notably New Jersey.

CODE PLEADING. The supposed difficulty in satisfactorily modifying or reforming the common-law system by mere statutory revision or amendment led in many of the United States to legislation abolishing the common-law system of pleading and creating or attempting to create a purely statutory form of pleading to be used in both law and equity actions. This step was first taken by the Legislature of New York, which adopted in 1848 the New York Code of Civil Procedure, which has served as a model for similar legislation in most of the other States adopting code procedure. A substantially statutory form of pleading and practice was also adopted in England by the Judicature Acts of 1873 and 1875. Under the codes discovery in equity actions is abolished. The pleader is allowed to plead the facts upon which he relies without formality. The pleadings are limited to two unless the defendant pleads a counterclaim, i.e. an independent action against the plaintiff, in which case the plaintiff may reply to it. The plaintiff's pleading is called a complaint, or in some States a petition, and in England a statement of claim. The defendant's pleading is called an answer, or in England a statement of defense. The defendant may demur to the plaintiff's complaint or to his reply to

defendant's counterclaim, and the plaintiff may demur to defendant's answer or counterclaim, and if the demurrer is overruled, the litigant is generally allowed to plead to the merits. Formal defects can only be taken advantage of by motion before trial, and great freedom of amendment is allowed. Despite its apparent simplicity, the code system has given rise to many difficulties not unlike those existing under the common-law system, and the question of further reform is still being agitated.

Consult, also, the authorities referred to under CIVIL LAW; EQUITY; LAW, CRIMINAL; CODE; etc.

PLEASANTON, plēz'ən-ton, ALFRED (1824-97). An American soldier, born in Washington, D. C. He graduated at West Point in 1844, and was assigned to the dragoons, with whom he served on the frontier and in Mexico. In 1855 he was promoted to a captaincy, and in February, 1862, was promoted to be major in the Second Cavalry, and participated in the Peninsular campaign, his command covering the retreat of the Federal army to Yorktown (August 18-19, 1862). He was commissioned brigadier-general of volunteers in July, 1862, and during the succeeding Maryland campaign he commanded the advance cavalry division. In the battles of South Mountain and Antietam his troops took conspicuous part. He participated in the battle of Fredericksburg, and at Chancellorsville especially distinguished himself by checking the flank attack of the Confederates on the Federal right. On June 7, 1863, he was given command of the cavalry corps of the Army of the Potomac, which he led in the Pennsylvania campaign that terminated at Gettysburg (July 1-3, 1863), where, on July 2d, he was brevetted colonel in the Regular Army for gallant and meritorious services. The next year he was transferred to the West, where he defeated General Price at Maraisdes-Cygnès (October 25, 1864), and drove the Confederates out of Missouri. He was brevetted major-general in the Regular Army in 1865, and on January 15, 1866, was mustered out of the volunteer service with rank of major-general. Two years later he resigned from the army, and after holding the positions of collector of internal revenue and commissioner, became, in 1871, president of the Terre Haute and Cincinnati Railroad.

PLEASURES OF HOPE. A poem by Thomas Campbell (1799), discussing the burning questions of the time, the French Revolution, the partition of Poland, and negro slavery. Though very successful in its day, it is tedious and rhetorical.

PLEASURES OF MEMORY. A didactic poem by Samuel Rogers (1792), the only want of which, Hazlitt remarked, is that of taste and genius.

PLEASURES OF THE IMAGINATION. A poem by Mark Akenside (1744), a didactic analysis of the pleasure excited by what is great, wonderful, and beautiful.

PLEBEIANS (OF. *plebeien*, Fr. *plébéien*, from Lat. *plebeius*, relating to the common people, from *plebs*, common people; connected with *plenus*, full, Gk. *πληθῆναι*, *plimlénai*, Skt. *pur*, *prá*, to fill, OChurch Slav. *plünü*, Lith. *pilnas*, OIr. *lán*, Goth. *fulls*, OHG. *fol*, Ger. *voll*, AS., Eng. *full*). The common people of Rome; one of the two elements of which the Roman nation consisted. Their origin, as a separate class, is to be traced partly to natural and partly to artificial causes. The foundation of Rome, probably as a frontier emporium of Latin traffic (according to Mommsen's suggestion), would bring about the place a number of inferior employees, clients, or hangers-on, of the enterprising commercial agriculturists who laid the primitive basis of the material and moral prosperity of the city. These hangers-on were the original plebeians or non-burgesses of Rome, whose numbers were constantly increased by the subjugation of the surrounding cities and States. Thus, tradition states that, on the capture of Alba, while the most distinguished citizens of that town were received among the Roman patricians, the greater part of the inhabitants, likewise transferred to Rome, were kept in submission to the *populus* or patricians of Rome—in other words, swelled the ranks of the plebeians. Similar transfers of some of the inhabitants of conquered towns are assigned to the reign of Ancus Martius. The order of plebeians thus gradually formed soon exceeded the patricians in numbers, partly inhabiting Rome, and partly the adjoining country. Though citizens, they were neither comprehended in the three tribes, nor in the *curiæ*, nor in the patrician *gentes*, and were therefore excluded from the *comitia*, the senate, and all the civil and priestly offices of the State. They could not intermarry with the patricians.

The first step (according to traditionary belief) toward breaking down the barrier between the two classes was the admission, under Tarquinius Priscus, of some of the more considerable plebeian families into the three tribes. Servius Tullius divided the part of the city and the adjacent country which was inhabited by plebeians into regions or local tribes, assigning land to those plebeians who were yet without it. The plebeian tribes, with tribunes at their head, formed an organization similar to that of the patricians. The same king further extended the rights of the plebeians by dividing the whole body of citizens, patrician and plebeian, into five classes, according to their wealth, and forming a great national assembly called the *comitia centuriata*, in which the plebeians met the patricians on a footing of equality; but the patricians continued to be alone eligible to the senate, the highest magistracy, and the priestly offices. These newly acquired privileges were lost in the reign of Tarquinius Superbus, but restored on the establishment of the Republic. Soon afterwards the vacancies which had occurred in the senate during the reign of the last King were filled up by the most distinguished of the plebeian equites, and the plebeians acquired a variety of new privileges by the laws of Valerius Publicola. The encroachments on those privileges on the part of the patricians began the long-continued struggle between the two orders, which eventually led to the plebeians gaining access to all the civil and religious offices, acquiring for their decrees (*plebiscita*) the force of law. Under the Hor-

PLECTOGNATH FISHES

1

1. A WEST INDIA GLOBEFISH (*Spheroides Spengleri*) puffed out.
 2. SMOOTH PUFFER (*Lagocephalus laevigatus*).
 3. TRIGGER-FISH (*Ballistes Carolinensis*).

4. FILEFISH (*Alutera scripta*).
 5. PORCUPINE-FISH (*Diodon hystrix*) puffed out.
 6. TRUNKFISH (*Lactophrys tricomis*).

tensian law (B.C. 286) the two hostile classes were at last amalgamated in one general body of Roman citizens with equal rights. Henceforth the term *populus* is sometimes applied to the plebeians alone, sometimes to the whole body of citizens assembled in the *comitia centuriata* or *tributa*, and *plebs* is occasionally used in a loose way for the multitude or populace, in opposition to the senatorial party. See PATRICIAN; ROME, HISTORY.

PLEBISCITE (Fr. *plébiscite*, from Lat. *plebiscitum*, decree of the people, from *plebis*, gen. sg. of *plebs*, people + *scitum*, decree, from *scire*, to know). The name given, in the political vocabulary of modern France, to a decree of the nation obtained by an appeal to universal suffrage. Thus, Louis Napoleon, for example, was made Emperor by a *plébiscite*. The word is borrowed from the Latin. (See PLEBEIANS.) The same institution has recently been making its way to the United States. (See REFERENDUM.) In almost every State the validity of certain measures is made dependent upon the approval of the electorate.

PLECOPTERA (Neo-Lat. nom. pl., from Gk. *πλέκω*, *plekein*, to twist + *πτερόν*, *pteron*, wing). An order of insects comprising the stone-flies. See STONE-FLY.

PLECTAMBONITES (from Gk. *πλεκτός*, *plektos*, twisted + *ἀμβών*, *ambōn*, ridge). A genus of brachiopods with shells of semicircular outline, dorsal valve concave and ventral valve convex, with long, low hinge areas, and with the shell surface marked by fine regular radiating ribs. Two species are common and well-known index fossils. *Plectambonites sericeus*, the earlier characteristic Ordovician species, has a wider, less convex form, with the ribs all of about the same size; while *Plectambonites transversalis* of the Silurian has a rounder, more convex form with several delicate ribs inserted between larger ribs. Both these species are found occupying their relative positions in the Ordovician and Silurian rocks of North America, Europe, and Asia.

PLECTOGNATHI (Neo-Lat. nom. pl., from Gk. *πλεκτός*, *plektos*, twisted + *γνάθος*, *gnathos*, jaw). A group of bony fishes, having the skeleton less perfectly ossified than in osseous fishes generally. It contains many highly aberrant forms, such as the globe-fishes. The maxillary bones are coëssified with the premaxillaries. The skin is usually tough or well armed with bony plates or spines. The fins are small, the spinous dorsal fin sometimes and the ventral fins always wanting. These fishes are for the most part passive creatures and depend upon their armature for protection. The order contains three suborders, namely, Sclerodermi, Ostracodermi, and Gymnodontes, and includes such forms as the trigger-fishes, trunk-fishes, puffers, etc. See Plate of PLECTOGNATHI FISHES.

PLECTOSPONDYLI (Neo-Lat. nom. pl., from Gk. *πλεκτός*, *plektos*, twisted + *σπόνδυλος*, *spondylos*, *σφόνδυλος*, *sphondylos*, backbone). A group of teleost fishes, which consists entirely of fresh-water forms, and includes about eight families, to which belong the majority of all the fresh-water fishes of the world. The essential character of the order, as defined by Jordan (*Fishes of North America*, Washington, 1896),

lies in the modification of the anterior vertebræ, as in the Nematognathi, but the opercular bones are all present and the skin bears scales. It contains the three well-marked suborders, Evertognathi (the carps, minnows, suckers, etc.), Heterognathi (the tropical characnids, etc.), Gymnototi (Gymnototidæ, etc.). Compare OSTARIOPHYSI.

PLECTRUM (Lat., from Gk. *πλήκτρον*, *pléktron*, instrument for striking, from *πλήσσειν*, *plēssein*, to strike). A small instrument made of ivory, tortoise-shell, metal, or wood, used for plucking the strings of certain musical instruments, like the zither and mandolin. In olden times it was simply held between the fingers, but now it is generally provided with a ring to slip over the thumb.

PLEDGE (OF. *plege*, Fr. *pleige*, OIt. *pieggio*, pledge; of uncertain etymology, perhaps ultimately from Lat. *præbere*, *præhibere*, to offer, from *præ*, before + *habere*, to have). Personal property delivered by one person to another to be held by him as security for the performance of an obligation, usually the payment of a debt. The term also denotes the legal transaction involved in making a pledge. The common-law pledge corresponds to the *pignus*, or pawn, under the civil law, although it cannot certainly be said that the common-law pledge was adopted from the civil law.

A pledge is distinguishable from a mortgage in that the relation of the pledgor and pledgee is that of bailor and bailee, the legal interest of the bailee being his right to possession of the pledge with power to sell it upon non-payment of the debt.

Any personal property actually in existence and capable of delivery into the possession of the pledgee may be pledged. Future property (that is, property not yet in existence, as a ship yet to be built or cloth yet to be made) cannot be pledged. An agreement, however, for the pledging of future property creates a valid equitable lien which a court of equity will enforce whenever the property comes into existence. The so-called inchoate or potential property which the common law regarded as present legal property, although in fact not in existence, as crops planted but not grown, or the wool to be grown upon sheep actually in existence, might also be pledged, while the mortgagee at common law acquired title to the mortgaged property.

The pledgee has a right to retain possession of the pledge only until the debt is paid or obligation performed. He is bound to exercise due or reasonable care in preserving and protecting the property pledged. Whenever the debt or obligation is due, he is entitled to sell the pledge and apply the proceeds to the payment of the debt, turning over the surplus, if any, to the pledgor. Before selling the property he is required to give fair and reasonable notice to the pledgor, and the sale should be made in such a manner as to secure the best price for the property. The usual method is by public auction at the place where property of the class pledged is usually sold. Notice of the sale and any particular method of sale may be waived by the pledgor. Equity also exercised its jurisdiction to foreclose a pledge by directing a judicial sale of the property pledged, thus giving to the pledgee a remedy in addition to his common-law right of

sale. An unauthorized sale or misappropriation of the pledge by the pledge amounts to a conversion of the property for which the pledgor may bring his action in trover or replevin.

In many States the law of pledge is regulated by statute, and in nearly all the States the power of one in the possession of personal property to pledge it is much affected by the Factor Acts (q.v.).

Consult: Colebrook, *The Law of Collateral Securities* (2d ed., Chicago, 1898); Jones, *The Law of Pledges* (2d ed., Boston, 1901); Tyler, *The Law of Usury, Pawns, or Pledges* (2d ed., Albany, 1882). Compare HYPOTHECATION.

PLÉIADE, plá'yád'. A name assumed by a group of scholarly French poets of the sixteenth century, seven in number, of whom Jean Daurat was master and Ronsard the best poet. The others were Belleau, Baif, Du Bellay, Jodelle, and Pontus de Thiard. Like seven Greek poets in the third century B.C. at Alexandria, they took the name *Pléiade*, from their number, on making their first declaration of principles, *La défense et illustration de la langue française*, by Du Bellay (1549). This aimed at a revival of classical studies, in the spirit of Petrarch, yet national and patriotic rather than erudite. Of the ethical and philosophic phases of the French Renaissance they were quite innocent, but its humanism reaches in them its fullest expression. (See BELLAY; BELLEAU; JODELLE; RONSARD.) Consult Pellissier's chapter on the *Pléiade* in Petit de Julleville's *Histoire de la langue et de la littérature française*, which has a good bibliography (Paris, 1896 et seq.); and essays by Brunetière in the *Revue des Deux Mondes* (ib., 1900 et seq.).

PLEIADES (Lat., from Gk. Πλειάδες, Πληιάδες). In Greek legend, according to the most general account, the seven daughters of Atlas and Pleione, the daughter of Oceanus. Of their story there seems to have been no canonical version, but various local legends were adopted by different writers. According to some they committed suicide from grief, either at the death of their sisters, the Hyades, or at the fate of their father, Atlas (q.v.); according to others, they were companions of Artemis (Diana), and being pursued by Orion (q.v.), were rescued from him by the gods by being translated to the sky. All agree that, after their death or translation, they were transformed into stars. As only six of these stars are easily visible to the naked eye, the story was told that Sterope hid herself from shame that she alone had married a mortal, while her six sisters were the loves of different gods. Others said that Electra, mother of Dardanos by Zeus, had withdrawn in grief at the fall of Troy. Their names are Electra, Maia, Taygete, Aleyone, Celeno, Sterope (the invisible one), and Merope. To the Greeks the constellation was important, since with their heliacal rising in May the navigation began, and with their setting in November it was supposed to close. They also served as guides for seed-time and harvest.

In astronomy the name designates a group of six stars placed on the shoulder of Taurus, the second sign of the Zodiac, and forming, with the polestar and the twin, Castor and Pollux, the three angular points of a figure which is nearly an equilateral triangle. Many believe, from the uniform agreement that the Pleiades were seven in number, that the constellation at an early

period contained seven stars, but that one has since disappeared—not a very uncommon occurrence.

PLEIOCENE EPOCH. See Pliocene Epoch.

PLEIOSAURUS, or **PLIOSAURUS.** See PLEIOSAURUS.

PLEISTOCENE PERIOD (from Gk. πλείστος, *pleistos*, most, superlative of πῶλος, *polys*, much many + καινός, *kainos*, new). The name introduced by Sir Charles Lyell to designate that period of geologic time which intervened between the end of the Tertiary and the beginning of the historic period. Within the last few years no other section of the earth's crust perhaps has received so much attention as the strata included under this name, and this is particularly true in America. The term Pleistocene is commonly used as synonymous with Quaternary, although some geologists tend to make two divisions of the Quaternary, namely, Pleistocene and recent. Other terms which are used are Post-Tertiary, Glacial Period and Ice Age. One of the most marked features of the Pleistocene was its cold climate and the great development of continental glaciers which formed and spread over a large portion of the globe as a result of these climatic conditions. The faunal and floral characters of the Pleistocene were not sufficiently different from those of the Pliocene to have permitted making it a separate division of geologic time on this account, for in those regions which were not covered by the ice-sheet we find that plant and animal life apparently continued on uninteruptedly from the Pliocene into the Pleistocene.

According to Geikie, there were six glacial and five interglacial stages in Europe, while in the United States Chamberlain considers that there were five glacial and four interglacial stages. The thickness of the continental ice-sheet must no doubt have been enormous, and in some of the mountainous districts in the east we find evidence of its presence on the mountains to a height of several thousand feet. The deposits formed by the ice at different localities and under different conditions are very varied, and are known under a variety of names, such as oskars, kames, over-wash plains, moraines, etc. The term drift is a general one applied to the deposits laid down either by the ice or by the waters flowing from it. The classification proposed by Chamberlain for the drift deposits is as follows:

Wisconsin till sheets (earlier and later).

Interglacial deposits (Toronto?).

Iowan till sheets,

Interglacial deposits.

Illinois till sheets,

Interglacial deposits (Buchanan).

Kansan till sheets,

Interglacial deposits (Aftonian).

Albertan drift sheets.

In the coastal plain region of the Atlantic States there occurs a great series of Pleistocene gravels and sand, known as the Columbian formation. These are the brick clays still extensively worked around Philadelphia, Baltimore, and Washington.

The Pleistocene period was marked by a depression of the land along the Atlantic coast and a temporary drowning of many of the river valleys, such as those of the Hudson River and of the Saint Lawrence. The subsequent elevation gave

rise to many lines of raised beaches which are represented in the terraces in the Hudson Valley and along Lake Champlain. A similar submergence occurred along the Pacific coast.

The animal and plant life of the Pleistocene was in some cases decidedly Arctic in its nature, but many species existed which are still living. The mammals were especially abundant. Those of North America included mastodons, elephants, tapirs, horses, and sabre-toothed tigers, as well as a giant beaver, while in South America the sloths were extraordinarily developed, some being equal in size to an elephant. In Europe the remains of the mammoth, hairy rhinoceros, the great cave-bear, and the Irish deer have been found.

PLENER, plá'nér, ERNST, Elder von 1841—). An Austrian statesman, son of Ignaz von Plener. He was born at Eger, and was educated at Vienna and Berlin. He served in the diplomatic corps (1865-73), and then entered the Imperial Diet, where he joined the Left, and supported Andrassy's policy in the Balkans (1878). He succeeded Herbst as head of the German Liberals, both in Prague and Vienna, and in 1888 was chosen leader of the party called "United German Left." From 1893 to 1895 Plener was a member of Taaffe's Cabinet as Minister of Finance, and in 1900, after five years at the head of the Court of Accounts, he entered the House of Lords. He wrote on English economic conditions, and a sketch of Ferdinand LaSalle (1884), as well as some valuable speeches delivered in the Bohemian Diet on the Bohemian school and language question (1886).

PLENER, IGNAZ, Edler von (1810—). An Austrian statesman. He was born in Vienna, studied law, and entered the governmental service, in which he showed much ability in finance. In 1859 he was made privy counselor; a year afterwards received the portfolio of finance and planned various important reforms, reviving the Bank Acts and the Ministry of Commerce before his resignation in 1865; and in 1867 he entered the Liberal Centralist Cabinet of Giskra as Minister of Commerce. This post he held until the fall of the Cabinet in 1870. He was a member of the Lower House until 1873, when he was appointed to the House of Lords. Plener was an ardent defender of a personal income tax, which he proposed in 1880 as a solution of financial difficulties.

PLENIPOTENTIARY. See ENVOY.

PLEROME (from Gk. πλῆρωμα, plērōma, a filling). The central embryonic region in stems and roots. It develops into the stele, in which the vascular system appears. See STEM.

PLESHTCHEYEFF, plësh-chá'yěf, ALEXEI (1825-93). A Russian poet, born at Kostroma, and educated at the University of Saint Petersburg. His first volume of poetry, published in 1845, was well received. In 1849 he became involved in a political complication, was accused of conspiracy against the Czar, and sentenced to be shot, but Nicholas I. commuted the death sentence to banishment to Orenburg, where Pleshtcheyeff enlisted in the army as a private soldier. Having distinguished himself in the Caucasus during the Crimean War, he was pardoned in 1857, and in 1872 made his home in Saint Petersburg. From this time he produced much original poetry and also translated poems of Heine, Byron, and Tennyson. In 1887 he published a complete collection of his verse.

PLESIOSAURUS (Neo-Lat., from Gk. πλῆσιος, plēsios, near + σαῦρος, sauros, lizard). A peculiarly interesting fossil marine reptile of the order Sauropterygia, found in the Liassic rocks of Europe. The order Sauropterygia comprises a number of reptiles which began as small amphibians in the Trias and culminated in the Cretaceous as larger forms fully adapted to marine habits of life. They had short thick lizard-like bodies, very long, flexible necks, small heads, and powerful tails. The early members had elongated limbs adapted for crawling on land, which became shortened and assumed paddle-like form in the later genera, but which never so thoroughly degenerated to fin-like organs as did those of the analogous group of ichthyosaurs (q.v.). Two families are recognized: *Nothosauridae*, comprising small more primitive forms, having five-toed feet with the normal number of finger bones or phalanges; *Plesiosauridae*, comprising large animals with paddle-shaped limbs

THE PLESIOSAURUS.

Outline of *Plesiosaurus dolichodeirus*, fossilized skeleton, and enlarged view of skull.

and the digits lengthened by an increased number of phalanges, and with the pectoral girdle enlarged to form a protective covering for the thorax. *Lariosaurus* and *Nothosaurus* from the Triassic of Europe are the important genera of the first family; and *Plesiosaurus* from the Liassic of Europe and *Cimoliosaurus* from the Cretaceous of America and New Zealand are representative of the second family.

The genus *Nothosaurus*, which attained a length of about ten feet, had a long flattened skull and small eyes near the middle of the head. The teeth were numerous, small and regular in the posterior portion of the jaws, but large and recurved, like spreading tusks, in the front. *Plesiosaurus* had a proportionately smaller head of triangular form and a neck which in some species exceeded in length the remainder of the body, and which was supported in the different species by from 25 to 40 cervical vertebrae. The teeth are not so numerous as in *Nothosaurus*, and are larger, recurved, and interlocking. The pelvic and pectoral limbs are remarkably similar to each other in form, and the phalanges of both were imbedded in cartilage which filled out the form of the paddle just as in the ichthyosaurs. These creatures varied from 10 to 20 feet in length, and they must have been very abundant in the Liassic seas of England and Germany, where finely preserved skeletons of them have been obtained. Twenty-five species are known in the Lias of England alone. *Pliosaurus* is a gigantic plesiosaur with a skull nearly five feet long and teeth twelve inches long, found in the English Upper Jurassic, and it is possibly a synthetic type between the ichthyosaurs and the plesiosaurs. American representatives of the plesiosaurs have been found in the Upper Jurassic beds of Alabama, New Jersey, Kansas, and Wyoming, and have been described under the names *Cimoliosaurus*, *Megalneusaurus*, *Elasmosaurus*, *Doliehorhynchops*, etc. A skeleton of Cope's *Elasmosaurus* from the Upper Cretaceous of Fort Wallace, Kansas, lacking the head, measures 42 feet in length, of which the neck, with 72 vertebrae, occupies 22 feet. Some of the American examples have afforded interesting evidence of the feeding habits of these creatures. Stones of various sizes from one-quarter inch to four inches diameter were found in the position of the stomach, and are supposed to have been swallowed by the animals as aids to digestion. One specimen had 125 such stones in its stomach. Plesiosaurs, as Cuvier expressed it, combine the paddles of a whale, the head of a lizard, and a long neck like the body of a serpent. They were powerful animals, swimming freely about the shallow seas of Jurassic and Cretaceous times, and feeding upon the fish and smaller marine reptiles, for preying upon which their long necks and numerous spreading teeth admirably fitted them.

(Topeka, 1893); id., "North American Plesiosaurs, Part I.," *Field Columbian Museum, Publication 73, Geological Series*, vol. ii., No. 1 (Chicago, 1903).

PLESSIS, plēs'sè', JOSEPH OCTAVE (1763-1825). A Roman Catholic prelate of Canada. He was born at Montreal. He entered the priesthood in 1801, was appointed coadjutor to Mgr. Denauet, Bishop of Quebec, and succeeded to the bishopric upon the death of that prelate in 1806. He obtained a royal charter for Nicolet College, where he instituted classical training, and founded the primary schools of Quebec. The British

Government did not immediately recognize his elevation to the office of bishop, claiming the right of nomination to the office within the province which the French Government had formerly possessed. But the Bishop successfully maintained his position in the controversy, and in 1818 he was summoned to the Executive Council of Canada by his episcopal title. In 1818 Quebec was made an archbishopric, but the Government never gave recognition to this titular advancement. He always showed great attachment to the British Crown and enthusiastically supported the Imperial relation. Consult his *Life* by Ferland (Quebec, 1864); and Kingsford, *History of Canada* (Toronto and London, 1888-98).

PLEURA (Neo-Lat., from Gk. πλεῦρά, rib, side). The name of a very delicate serous membrane externally investing the lung, which, after inclosing the whole organ, except at its root, where the great vessels enter it, is reflected upon the inner surface of the thorax or chest. That portion of the pleura which is in contact with the surface of the lung is called the *pleura pulmonalis*, or visceral layer, while that which lines the interior of the chest is called the *pleura costalis*, or parietal layer, and the space intervening between these two layers is called the *cavity of the pleura*. Each pleura is a closed sac, and quite independent of the other. The central interspace between the right and left pleuræ is termed the *mediastinum*, and contains all the viscera of the thorax excepting the lungs. The inner surface of each pleura is smooth, glistening, and moistened by a serous fluid; the outer surface is closely adherent to the surface of the lung, to the roots of the pulmonary vessels as they enter the lung, to the upper surface of the diaphragm, and to the walls of the chest. The lobes of the lungs are separated from one another by involutions or in-foldings of the visceral layer. The use of these serous sacs is much the same as that of the *peritoneum* (q.v.); each pleura retains the lung and to a certain extent the greater vessels in position, while it at the same time facilitates, within certain limits, the movements of those parts which are essential to the due performance of the act of respiration.

PLEURACANTHUS (Neo-Lat., from Gk. πλεῦρόν, *pleuron*, rib + ἀκανθα, *akantha*, spine). A fossil shark-like fish found in the Carboniferous and Permian rocks of North America, Europe, and Australia. The body was long and tapering, with a linguatè diphycercal caudal fin. The dorsal fin extended almost the entire length of the back and was separated from the upper lobe of the caudal fin by only a slight notch. On the top of the head was a long, posteriorly directed strong spine, which was hollow and armed with longitudinal rows of barbs. The pectoral and pelvic fins were large and there were two small anal fins. Several complete skeletons of this fish have been found in the European Carboniferous rocks.

PLEURISY (Fr. *pleurésie*, from Lat. *pleuritis*, *pleuritis*, from Gk. πλεῦρις, *pleurisy*, from πλεῦρά, *pleura*, rib). An inflammation of the pleura, the serous membrane investing the lungs. This membrane, like the pericardium (q.v.) and the peritoneum (q.v.), consists of two layers, a visceral and a parietal, the former closely attached to the lungs, and the latter applied to

the interior of the chest wall. These two layers are normally everywhere in contact and move upon each other freely during respiration, a lubricating fluid being secreted for this purpose. A space between the visceral and parietal portions of the membrane, called the pleural cavity, exists only under pathological conditions, and may be occupied either by air or fluid.

Pleurisy may be acute or chronic, primary or secondary, plastic (dry) or characterized by an effusion of fluid. It occurs after exposure to cold; as a secondary process in acute diseases of the lung, as pneumonia, which is always accompanied by a greater or less amount of dry pleurisy; as a result of injuries; or as an effect of rheumatism. The most frequent cause, however, is tuberculosis; recurrent attacks of pleurisy are almost always tubercular in character.

In the dry or plastic form of pleurisy the affected area of the membrane becomes congested and opaque, roughened, and covered with a sheathing of lymph, of variable thickness. The process may be arrested at this point, the exudate be absorbed, and complete recovery take place; or the plastic exudate may become organized and produce permanent adhesions between the two pleural layers. These adhesions are in the form of patches or bands, and in proportion to their extent limit the movements of the lungs in the chest cavity.

In pleurisy with effusion there is thrown out a varying amount of sero-fibrinous fluid, pale yellowish in color, or brownish at times from extravasated blood. In composition this closely resembles the serum of the blood. The effusion may be so small in quantity as to cause no symptoms and escape notice. When considerable in amount, the lung is compressed, the heart and other organs displaced, and respiration and circulation seriously interfered with. Small quantities of fluid are readily absorbed, but large effusions may persist for months unless reduced by surgical means. In some cases the effusion is limited to the diaphragmatic portion of the pleura (diaphragmatic pleurisy); in others only the portion between the lobes of the lung is involved (interlobular pleurisy). A hemorrhagic effusion sometimes occurs during the course of certain malignant fevers and in cachectic states of the body.

A pleuritic exudate may become infected by pus-producing bacteria which multiply very rapidly and soon convert the fluid into a purulent material. This condition is called empyema, and is a very grave complication. The pleural cavity is converted into what is practically a large abscess, which may evacuate itself by burrowing through the lung substance to a bronchial tube and being coughed up; or it may penetrate the chest wall; or make its way through the diaphragm into the peritoneal cavity and set up a general peritonitis. The affection is more common and less fatal in children than in adults. In the former a favorable result may be expected, particularly if the pus is evacuated early. Some cases recover spontaneously.

The most prominent symptoms of pleurisy are chills, fever, stitch in the side, and a dry, unproductive cough. The pain is at first severe, and is exaggerated with every movement of the body, by coughing, sneezing, etc. Respiration is difficult and shallow, and the patient lies upon his

back or on the healthy side. After effusion has taken place pain is less marked, and the patient lies on the affected side, in order to give the healthy lung full play. In addition to these symptoms there exist general malaise, weakness, loss of appetite, and a quick pulse. Empyema is marked by irregular temperature, chills, and sweats.

The physical signs of dry pleurisy are impaired motion on the affected side and a friction sound caused by the rubbing together of the inflamed surfaces. When the effusion has occurred, this sound disappears, there is a loss of pulmonary resonance, and dullness or flatness on percussion over the area occupied by the effusion. The side involved is larger than the other, the intercostal spaces are obliterated or bulge. The heart may be displaced upward or to one side, so that the apex beat is felt out of its normal place, or entirely hidden behind the sternum.

A sero-fibrinous pleurisy may persist for months, and the lung, from the long-continued pressure, become permanently contracted, so that when the fluid is absorbed or drawn off it fails to return to its normal dimensions and to fill the whole cavity. Adhesions may help to produce this condition.

The treatment of dry pleurisy comprises rest in bed, saline catharsis, and relief of pain by the administration of sedatives or by counter-irritation in the form of a mustard plaster or the application of the electro-cautery. Strapping the chest with long strips of adhesive plaster gives comfort by limiting respiratory movements. Pleurisy with effusion requires a somewhat different plan of treatment. To favor absorption of the exudate, the diet is made light and dry, and daily concentrated doses of Epsom salt are given to promote elimination. The skin and kidneys are also kept active with diaphoretic and diuretic medicines. Mild counter-irritation with mustard or iodine is useful in the later stages. When the effusion is large and resists all ordinary methods of treatment, aspiration of the fluid or part of it is practiced. This is accomplished by puncturing the chest wall with a hollow needle attached to a suction pump. The operation is simple and not painful, and is sometimes done merely to determine the nature of the exudate. The fluid is withdrawn slowly, the amount depending on the size of the effusion. In some cases a quart or more can be abstracted with safety. Frequently the withdrawal of a small amount will be followed by spontaneous absorption of the remainder. Purulent pleurisy—empyema—is treated by making an incision into the chest wall and allowing the pus to escape, washing out the cavity and draining it. This operation dates from the time of Hippocrates and is not a serious procedure. The cavity is gradually filled by the expansion of the lung and the falling in of the chest wall. Sometimes it is necessary to remove portions of one or more ribs. Expansion of the lung is promoted by systematic breathing exercises.

PLEURISY ROOT. One of the milkweeds. See BUTTERFLY-WEED.

PLEURODYNIA (Neo-Lat., from Gk. *πλευρά*, *pleura*, rib + *δύνη*, *odynē*, pain). A rheumatic affection of the intercostal muscles on one side, characterized by acute pain in the side upon taking a full breath or coughing, and by tenderness on pressure. The respiratory movements

are restricted as much as possible on account of the pain. The disease is difficult to distinguish from intercostal neuralgia, in which disease, however, the pain is usually more limited and paroxysmal, and there are tender points along the course of the nerves. If it happens to be attended by a slight febrile excitement and a cough, pleurodynia closely resembles pleurisy (q.v.), but the physical signs of the latter affection are wanting. The pain may be completely relieved by strapping the chest with strips of adhesive plaster. Mild counter-irritation and stimulating liniments are very often useful. The general treatment is that of rheumatism (q.v.).

PLEURONECTIDÆ. See FLATFISH; FLOUNDER.

PLEUROPNEUMONIA (Neo-Lat., from Gk. πλεῦρά, *pleura*, side + πνευμονία, *pneumonia*, pneumonia), LUNG PLAGUE, LUNG FEVER, PERIPNEUMONIE (Fr.), LUNGENSEUCHE (Ger.). A malignant contagious disease of cattle, characterized by an inflammatory process accompanied by exudation on the pleura and in the lungs. The disease has been recognized in Europe since the close of the eighteenth century. Domestic cattle, the buffalo, and the yak are most susceptible to it. Goats, pigs, horses, and carnivora are very resistant, and man is immune. It occurs at present in Europe, Asia, Africa, and Australia. It has been eradicated from Great Britain, the last case having been observed in 1896. The disease was introduced into the United States in 1843, and was finally eradicated through the efforts of the Bureau of Animal Industry in 1892. Consult Law, "The Lung Plague of Cattle," in the *Farmers' Veterinary Adviser* (Ithaca, N. Y., 1892).

PLEUROTOMARIA (Neo-Lat. nom. pl., from Gk. πλεῦρον, *pleuron*, rib + τομάριον, *tomarion*, diminutive of *τόμος*, *tomos*, cut, slice, from τέμνειν, *temnein*, to cut). The typical genus of Pleurotomaridae, a family of scutibranchiate gastropods. While quite rare at the present time, this genus was abundantly represented in the seas of the Paleozoic, Mesozoic, and Cenozoic eras. Its ancestral form is apparently the genus Raphistoma, a small shell of the early Ordovician, with low spire and sharply angular whorls. Pleurotomaria itself, with elevated spire and prominent slit band, made its appearance in the Silurian, and with a great variety of forms and allied genera it attained its maximum in the seas of Mesozoic time, since when it has been gradually declining to the present time. This large genus, embracing several hundred species, is split up into a number of subgenera. One of the most important allies of Pleurotomaria is the Paleozoic genus Murchisonia (q.v.).

PLEVNA, plév'ná, or **PLEVEN**. A town of Bulgaria, situated on a tributary of the Danube and on the Sofia-Varna Railway, about 85 miles northeast of Sofia (Map: Balkan Peninsula, E 3). The town has a considerable trade in cattle and wine. It is connected by a branch railway line with the Danube. Population, in 1900, 18,709.

Plevna is famous for the rôle which it played in taking the Russo-Turkish War of 1877. Garrisoned only by a small Turkish force at the beginning of the war, the place became, after the taking of Nikopoli by the Russians (July 16,

1877), the centre of operations in the western part of the theatre of war in Bulgaria. Just as the Russians were preparing to march toward Sofia, Osman Pasha arrived with a part of his army at Plevna. The Turkish forces at that point now amounted to 17,000 men with 58 guns, and the Russians dared not advance leaving this unexpected enemy in their rear. On July 20, 1877, an assault by a comparatively small force of Russians was repulsed, their loss being about 2800 men. The result of the first assault revealed to the Russians the strength of the Turkish forces at Plevna, and accordingly the Russian forces were increased to about 32,000 men, with 176 guns. The second attack, on July 30th, led by General Krüdener, was also unsuccessful, and the Russians lost over 7000 men. The besieging army was augmented by about 35,000 Rumanians, while the Turkish forces were also increased to about 36,000 men, with 70 guns. On September 7th the bombardment was resumed, and in a desperate assault on September 11th General Scobelev captured three trenches, but was compelled to abandon them on the following day. The Russians and Rumanians lost nearly 16,000 men between September 7th and 11th, and it was then decided to invest the town by a large army and compel its surrender by cutting off its supplies. These operations were successfully carried out under the direction of Tottleben, and the besieged army, which had by that time been increased to about 45,000 men, soon began to suffer from lack of supplies and ammunition. Osman Pasha finally decided to break through the Russian chain, and accordingly crossed the Vid with his entire army on the night of December 9-10, and after an unsuccessful attack was thrown back toward the river, but, unable to cross the stream, surrendered unconditionally after a hard fight, in which he himself was wounded. The Russians took 40,000 prisoners and 77 guns. The total loss of the besieging army in killed and wounded was about 40,000 men.

Consult: Osman Pasha, *Défense de Plevna, d'après les documents réunis par Mouzaffer Pasha et Taalat Bey* (Paris, 1889); Herbert, *The Defense of Plevna* (London, 1895).

PLEXIMETER. See PERCUSSION.

PLEYEL, plé'el, IGNAZ (1757-1831). An Austrian composer, born in Ruppersthal, near Vienna. He studied music under Wanhal and Haydn, and made in early life an extensive tour of Italy to hear the works of the best composers. In 1783 he was made kapellmeister of the Strassburg Cathedral, and there composed most of the works on which his popularity rests. In the winter of 1791-92 he was engaged as the conductor of the London Professional Concerts. He returned to Strassburg and subsequently went to Paris (1795), and after a successful career in that city as a publisher of music and pianoforte manufacturer under the firm name of Pleyel, Wolff et Cie, retired to an estate which he had purchased near the capital. His compositions, consisting of quartettes, concertantes, and sonatas, are full of agreeable melodies, sometimes light and trivial, but occasionally giving evidence of genius. He died on his own estate, near Paris.

PLIANT, DAME. A pretty, silly widow in Ben Jonson's comedy *The Alchemist*.

PLIANT, SIR PAUL. A henpecked, stupid husband in Congreve's *Double Dealer*. Lady Pliant is a handsome, silly woman who rules her old husband and presumes on his blindness.

PLICA (Neo-Lat., from Lat. *plicare*, to fold), **TRICHOMA**, **PLICA POLONICA**. A condition in which the hair of the scalp, the beard, or the hair of the pubes becomes matted together, forming a stiff mass or a firm rope, which is exceedingly difficult to disentangle. The condition is observed among the inhabitants of Galicia, Posen, Poland, and Silesia, and is due to neglect, especially during illness. It was formerly regarded as a disease. Naturally, such a mass becomes easily infested with fungi and vermin. Superstition prevents cutting or combing the hair, as the matting is believed to prevent sickness and misfortune.

PLIMSOLL, plim'sol, SAMUEL (1824—). An English reformer, known as 'The Sailor's Friend.' He was born and educated in Bristol. As a coal dealer in London he began to take an interest in the carrying trade and to remark upon the risks to sailors in being shipped upon over-laden or unseaworthy vessels, largely insured. As a member of Parliament (for Derby), and by his book *Our Seamen* (1873), he aroused so much discussion of the abuses that his measures for reform ultimately were adopted. His *Cattle Ships* (1890) was written with a view to reformation in that branch of the merchant service, and his name is remembered by the 'Plimsoll mark' on all ships above which they must not be laden. See **LOAD LINE OF VESSELS**.

PLINTH (Lat. *plinthus*, from Gk. πλινθος, brick, tile, plinth). The square member at the bottom of the base of a column. Also the plain projecting band forming a base of a wall.

PLINY THE ELDER, GAIVS PLINIUS SECUNDUS. The author of the celebrated *Historia Naturalis*. He was born in the north of Italy, probably Novum Comum (*Como*), A.D. 23. Whether it was his birthplace or not, Novum Comum was certainly his family's place of residence, since he had estates in its neighborhood. While still young he was sent to Rome, where his ample means and high connections secured him the best education. At the age of twenty-three he entered the army, and served in Germany as commander of a troop of cavalry under Lucius Pomponius Secundus, of whom, in later life, he wrote a memoir. He traveled over nearly all the frontier of that extensive province, visited the Chauci and the sources of the Danube, composed during the intervals of military duty his treatise *De Iaculatione Equestri*, and commenced a history (afterwards completed in twenty books) of the Germanic wars. On his return to Rome in 52 with Pomponius, he entered on the study of jurisprudence; but his pleading was unsuccessful, and, accordingly, he retired to his native place. There he wrote his *Studiosus*, a treatise in three books on the training of a young orator from the nursery to his entrance on public life, and apparently intended to guide the education of his nephew; also his grammatical work, *Dubius Sermo*, in eight books. Shortly before Nero's death we find him a procurator in Spain, where, in 71, he heard of his brother-in-law's decease, and of his being intrusted with the guardianship of his nephew, Pliny the Younger, whom he adopted on his return to Rome before 73. Ves-

pasian, the reigning Emperor, whom he had known while in Germany, received him as one of his most intimate friends; and it was at this period that he completed, in 31 books, and brought down to his own time the Roman history of Aufidius Bassus. His mode of study at this time was a model of systematic assiduity. He would begin his studies by candle-light in autumn at a late hour of the night, and in winter at one or two in the morning. Before daybreak he would call on the Emperor, for whom he would proceed to execute various commissions; this done he would return home and resume his studies. A slender meal would follow; after which he would take notes or extracts from the books which were read to him. The practice of jotting down important facts or observations was habitual with him, and he was often heard to say that there was no book, however bad, from which some good could not be got. A cold bath, followed by a light meal and a short sleep, occupied another interval, after which he would study till the *cena*, or dinner-time. Even at this meal some book was read to him on which he would make comments. When on a journey, again, he was never without a secretary at his elbow, provided with a book and tablets. By this mode of life he collected an immense mass of materials, from which he compiled his great *Historia Naturalis*, published about 77. No fewer than 160 *volumina* of notes were found at his death, two years afterwards. At the time of the great eruption of Vesuvius, which overwhelmed Herculaneum and Pompeii, in 79, he was stationed off Misenum, in command of the Roman fleet. Eager to examine the phenomenon more closely, he landed at Stabia, where he was suffocated by the vapors caused by the eruption. He was, as his nephew tells us, corpulent and asthmatic, and so sank the more readily. None of his attendants shared his fate. The story of his death is described in two letters of his nephew, Pliny the Younger, to Tacitus, written many years after the event (v., 16 and 20).

Of all his works, only his *Historia Naturalis* has come down to us. It comprehends astronomy, meteorology, geography, mineralogy, zoölogy, botany, everything, in short, which is a natural or non-artificial product. Moreover, the work is interspersed with digressions on such subjects as human institutions and inventions, and the history of the fine arts. It is divided into 37 books, the first of them being a dedicatory epistle to Titus, with a table of contents of the remaining books, and embraces, as we are told in the preface, 20,000 matters of importance, extracted from about 2000 volumes. Its scientific merit is not great. There is little attempt at philosophical arrangement; the observations are nearly all taken at second hand, and show small discrimination in separating the true from the false, or the probable from the marvelous. His meaning is often obscure, owing to his lack of personal acquaintance with the matters of which he treats and his failure to grasp the true sense of the authors whom he cites or translates. But the work is a great monument of industry and research, and most valuable as supplying us with details on a great variety of subjects as to which we have no other means of information. The best critical editions of the text are those of Sillig (8 vols., Gotha, 1851-58); Jan (Leipzig, 1875-80); and Mayhoff (a recension of Jan,

Leipzig, 1875-97). There is an old English translation by Holland (London, 1601), and a more recent one, in Bohn's Library, by Bostock and Riley (London, 1855-57). Pliny's chapters on the history of art are edited, with commentary, by Jex-Blake and Sellers (London, 1896).

PLINY THE YOUNGER (GAIUS PLINIUS CÆCILIUS SECUNDUS). A nephew of Pliny the Elder, and son of Gaius Cæcilius. He was born at Novum Comum (Como), A.D. 62. He was still young when he lost his father, and was adopted by his uncle, under whose care, and that of his mother, Plinia, and his tutor, Virginius Rufus, his education was conducted. Passionately devoted to literature, he wrote a Greek tragedy at the age of thirteen. He studied eloquence under Quintilian, and became so famous for his literary accomplishments that he acquired the reputation of being one of the most learned men of the age. His oratorical powers were also considerable; in his nineteenth year he began to speak in the Forum, and his services as an advocate before the court of the centumviri and the Roman Senate were in frequent request. He held numerous official appointments; served, while a young man, as *tribunus militum* in Syria, where he listened to the teaching of Euphrates the Stoic, and Artemidorus; was afterwards *quæstor Cæsaris*; was prætor about 93, and consul in 100, when he wrote his *Panegyricus*, an adulatory eulogium of the Emperor Trajan. He was appointed, in 103, proprietor of the Province Pontica or Bithynia, an office which he vacated in less than two years; and he also discharged the function of curator of the banks and channel of the Tiber. He was twice married, his second wife being Calpurnia, granddaughter of Calpurnius Fabatus. Our knowledge of Pliny the Younger is mainly derived from his letters or *Epistulae*, of which there are ten books. He collected them himself, and probably wrote many of them with a view to publication. They hold a high place in epistolary literature, and give us many interesting glimpses into the life of their author and his contemporaries. Pliny himself appears in them to considerable advantage, as a genial and philanthropic man, enamored of literary studies, and fond of improving his estates by architectural adornment. His ample fortune was liberally bestowed, and his slaves always found in him an indulgent master. He never enjoyed robust health; but of the time or cause of his death we know nothing. Of his letters, one of the most interesting is the one to the Emperor Trajan (Book x., 97), written while Pliny was Governor of Bithynia, and asking for instruction in regard to the policy to be pursued against the stubborn sect of Christians; this is one of the earliest notices of the Christians in Roman writers. The best editions of Pliny's *Panegyricus* and *Epistulae* together are those of Schæfer (Leipzig, 1805) and Keil (ib., 1892); of the *Epistulae* alone, that of Gierig (ib., 1806). Of English translations, there are the *Panegyricus* by Bond (London, 1724) and the *Epistulae* by Melmoth (ib., 1746); 10th ed. 1805) and Lord Ormery (ib., 1752). An excellent sketch of Pliny's life by Rendall is printed in Mayor's edition of Book iii. of the *Epistulae* (ib., 1880).

PLIOCENE EPOCH (from Gk. *πλειών*, *pleiōn*, more, comparative of *πολύς*, *polys*, much, many

+ *καιρός*, *kainos*, new). The name given by Sir Charles Lyell to the uppermost division of the Tertiary system. Pliocene rocks are not extensively developed in America, but in Europe they are of great importance. Along the Atlantic coast of the United States isolated areas have been found from Virginia southward to Florida; and similar patches occur on the Pacific coast, the Merced series of the San Francisco peninsula having a thickness of nearly 6000 feet. In the interior there are a number of Pliocene basins in which fresh-water strata were deposited. The Goodnight and Blanco stages of Texas and similar strata in Kansas, Oklahoma, and Oregon were laid down in fresh-water lakes. The Pliocene of Europe comprises extensive deposits in Spain, France, Italy, Sicily, and Greece, and smaller areas in Belgium, Northern France, and England. The life of the Pliocene epoch is quite modern in character, although many species of both plants and animals are no longer existent. The rhinoceros, horse, llama, sloth, mastodon, and peccary inhabited North America at that time, while the European fauna included many forms which resemble those living at present in Africa. See TERTIARY SYSTEM.

PLIOSAU'RUS (Neo-Lat., from Eng. *pliocene* + Gk. *σαῦρος*, *sauros*, lizard). A gigantic Plesiosaurus with large head and short neck. See PLESIOSAURUS.

PLOCK, plótsk. A government occupying the northwestern part of Russian Poland, bounded by Prussia on the north. Area, 3674 square miles. The surface is slightly elevated toward the north and slopes toward the valley of the Vistula. The chief rivers are the Vistula, which forms the southern and western boundaries of the government, and the Narev. The soil is well adapted for agriculture, which is the chief occupation. Rye, potatoes, oats, and beets are the principal agricultural products, the last named being raised for the beet-sugar mills in the governments of Plock and Warsaw. Stock-breeding is also important. The manufacturing industries are confined mostly to the production of sugar, flour, spirits, and trimmed lumber. Population, in 1897, 556,877.

PLOCK. One of the oldest cities of Russian Poland and capital of the Government of Plock, picturesquely situated on the right bank of the Vistula, about 60 miles west-northwest of Warsaw (Map: Russia, B 4). It is a pretty town with a fine public garden, a town hall, a cathedral founded in the twelfth century, two gymnasias, a seminary for teachers, a theatre, and a number of libraries. The manufacturing industries are of little importance, but there is a considerable trade in grain, which is carried by the Vistula to Germany. Population, in 1897, 27,073. Plock is mentioned in connection with the introduction of Christianity into Poland in the tenth century. It was the capital of the mediæval Principality of Masovia.

PLOCK'HORST, BERNHARD (1825—). A German historical painter, born at Brunswick. Having practiced drawing and lithography in Berlin and Dresden, he took up painting in 1850 at Munich under Piloty, and in 1851 studied in Paris under Couture. A visit to Belgium and Holland in 1854 was followed by a sojourn in Italy, especially at Venice, whereupon he settled first at Leipzig, then in Berlin, whither he re-

turned after having been professor at the School of Art in Weimar from 1866 to 1869. His religious paintings excel in lofty conception, great truthfulness and depth of expression, and a masterly technique, placing him in the front rank as a colorist. Foremost among them is the "Contest of Archangel Michael with Satan for the Body of Moses" (1861-66) in the Cologne Museum, and other noteworthy specimens include "Mary and John Returning from Christ's Tomb," in the Löwenstein Gallery at Moscow; "Christ and the Adulteress," "Mater Dolorosa" (1860), both in the Leipzig Museum; and "Resurrection" (1867), in the Cathedral at Marienwerder. Among his more recent works may be mentioned "Christ's Entry into Jerusalem" (1892) and "Abide with Us" (1895). Of several meritorious portraits, those of Emperor William I. and Empress Augusta (1876) are in the National Gallery, Berlin.

PLOESTI, plô-ès'té. A town of Rumania. See **PROYESHTI**.

PLOMBIÈRES, plôn'byâr'. A fashionable watering-place in the Department of Vosges, France, 13 miles south of Epinal (Map: France, N 4). It is picturesquely situated in a deep valley on the Aurgonne and is celebrated for a number of mineral and thermal springs, known since the time of the Romans. The place was embellished by Stanislas Leszczynski in the eighteenth century, and by Napoleon III. in the nineteenth. There are sumptuous public and private bath-houses, a hospital founded by Stanislas, two large hotels, a casino, a park, and promenades. Population, in 1901, 1830. At Plombières in July, 1858, occurred the secret meeting between Napoleon III. and Cavour which led to the conclusion of an alliance between France and Sardinia against Austria. See **ITALY**; **CAVOUR**.

PLONGÉE, plôn'zhâ' (Fr., plunged). In military science, a term meaning a slope toward the front. The plongée of a shell in artillery fire is that part of the curve of the trajectory between its highest altitude and the point at which it strikes the earth. In fortification the plongée is the superior slope of the parapet toward the front. The slope of the latter varies from 1 in 9 to 1 in 4.

PLÖNNIES, plë'nëz, **LUISE VON** (1803-72). A German lyricist and religious poet, born at Darmstadt. Her sketches of travel in Belgium, published in 1847, won her election to the Brussels Royal Academy. Her lyric ability is best shown by her translations: *Britannia* (1843), *Englische Lyriker des 19. Jahrhunderts* (1863), and *Sav-etri* (1862; 3d ed. 1867); as well as by her original works: *Gedichte* (1844); a sonnet sequence, *Abälard und Heloise* (1849); and *Die sieben Raben* (1862; 3d ed. 1866). Of her religious poems the best known are: *Lilien auf dem Felde* (1864); a drama, *Maria Magdalena* (1870); and *David* (1873).

PLÖNNIES, **WILHELM VON** (1828-71). A German military writer, son of Luise von Plönnies. He was born in Darmstadt, entered the Hessian infantry at sixteen, fought in the campaign of 1848-49 in Baden, and resigned in 1861. In belles-lettres he made himself known by a version of *Kudrun* (1853), by the poems *Immortellen des Schlachtfeldes* (1870) and *Schwanelieder* (1871), and by a humorous novel, *Leben,*

Wirken und Ende des Generals Leberecht vom Knopf (1869; 2d ed. 1877; written under the pseudonym Ludwig Siegrist). His works on fire-arms are very valuable. They include: *Neue Studien über die gezogene Feuerwaffe der Infanterie* (1861-64), *Das Zündnadelgewehr* (1865), *Hinterladungsgewehre* (1867), and, with Weygandt, *Die deutsche Gewehrfrage* (1871).

PLON-PLON, plôn' plôn'. A name given to Prince Napoleon, son of Jerome Bonaparte, in allusion to his cowardice in the Crimean War. The word is a corruption of *plomb-plomb* (lead).

PLOTINUS (Lat., from Gk. Πλωτῖνος). The most original and important philosopher of the Neo-Platonic school. He was born at Lyeopolis, in Egypt, about A.D. 205; but such was his utter indifference to things human, "being ashamed almost to live in a body," that he never would divulge even his parentage. He would never allow his birthday to be celebrated, although he gave feasts on those of Socrates and Plato; nor would he ever permit a painter or sculptor to perpetuate his features, or, as he called it, to produce the image of an image—the body being to him only a faint image of existence. His body was altogether contemptible in his eyes; he would see no physician in his illness, and was very sparing in the use of food, refraining from meat, often even from bread. Strangely enough, his desire for the study of philosophy did not arise within him before his twenty-eighth year, when he repaired to Alexandria, and there, after having sat at the feet of the great masters for some time without feeling satisfied with their teachings, he at last became acquainted with Ammonius Saccas, and in him found the desired teacher. For ten years he zealously attended his lectures, and although he had agreed, with two fellow-students, never to make known aught of Ammonius's teachings to the world, he yet became the chief representative and author of that school, less as a pupil than as an independent thinker, who, taking his stand upon its theorems, developed them to their full extent. In 242 he joined Gordianus's expedition to Persia, in order to devote himself to the philosophy of India and Persia; but the Emperor being murdered in Mesopotamia, he had to repair hurriedly to Antioch, whence, in 244, he went to Rome. His lectures here were attended by crowds not only of eager youths, but of men and women of the highest circles. Not only Platonic wisdom, in Neo-Platonic garb, but asceticism and the charm of a purely contemplative life, were the themes on which he, in ever-new variations, and with an extraordinary depth and brilliancy, held forth; and such was the impression his earnestness made upon his hearers, that several of them really gave up their fortunes to the poor, set their slaves free, and devoted themselves to a life of study and ascetic piety. Dying parents intrusted their children and money to him, well knowing that a more honest guardian, and one more anxious for his charges, could not be found. It is hardly surprising to find that his contemporaries coupled with his rare virtues the gift of working miracles. At the age of sixty he thought of founding an aristocratical and communistic commonwealth on the model of Plato's Republic, and obtained from the Emperor Gallienus a grant of two cities in Campania as a site for his 'Platonopolis;' but courtiers prevented the fulfillment of this promise. Plotinus died in

270. at Puteoli (now Pozzuoli), when sixty-six years of age.

Plotinus's system was based chiefly on Plato's theorem of the ideas; only that while Plato assumed the ideas to be the link between the visible and the invisible, or between the supreme Deity and the world, Plotinus held the doctrine of emanation, that is, the constant transmission of powers from the absolute to the creation, through several agencies, the first of which is 'pure intelligence,' whence flows the 'soul of the world,' whence, again, the souls of 'men' and 'animals,' and finally 'matter' itself. Men thus belong to two worlds, that of the senses and that of pure intelligence. It depends upon ourselves, however, to which of the two worlds we direct our thoughts most and finally belong. The ordinary virtues, as justice, moderation, valor, and the like, are only the beginning and very first preparation to our elevation into the spiritual realm; purification, or the exercise of *purifying* virtues, is a further step, to which we attain partly through mathematics and dialectic; and the abandonment of all earthly interests for those of intellectual meditation is the nearest approach to the goal. The higher our soul rises in this sphere of intellect, the deeper it sinks into the ocean of the good and the pure, until at last its union with God is complete, and it is no longer thought but vision and ecstasies which pervade it. He held a mysterious belief in a kind of metempsychosis, by which souls, not sufficiently purified during life, return after death, and inhabit, according to their bent, men, animals, or even plants. He further held views of his own respecting gods and demons, whom he divided into different classes, according to their degrees; and professed faith in mantie, astrology, and magic, the conviction of the truth of which sciences he derived from his theory of the harmony in the intellectual world reflected by the material world. Yet it is clear from his dicta on these subjects that he did not believe in these so-called sciences in the gross sense of the herd, but that he had a vague knowledge of those mysterious laws of attraction and repulsion which go through nature. Plotinus's philosophy, which, as it were, tried to combine all the systems of Anaxagoras, Parmenides, the Pythagoreans, Plato, and Socrates, and the Stoa into one, was the last and boldest attempt of the ancient Greek world to explain the mystery of the creation and of existence. Its influence upon modern philosophy is remarkable. From Spinoza to Schelling, the reminiscences of Plotinus, irrespective of the drift of particular parts of their systems, recur constantly. See NEO-PLATONISTS.

Plotinus's works were well-nigh forgotten, when Marsilius Ficinus first published a Latin paraphrase of them (Florence, 1492), which was followed by the *editio princeps* of the original (Basel, 1580 and 1615). The first critical edition, however, is due to Creuzer (Oxford, 1835, 3 vols.). Others are those of Dübner (Paris, 1855), Kirchoff (1856), and Volkmann (Leipzig, 1883-84). Parts of his works were translated into German by Engelhard (1820); into English by Taylor (1794 and 1817); into French by Bouillet (1861). Consult: Kirchner, *Die Philosophie des Plotinus* (Halle, 1854); Richter, *Neuplatonische Studien* (ib., 1864-67); Brenning, *Die Lehre vom Schönen bei Plotin* (Göttingen, 1864); Kleist, *Plotinische Studien* (Hei-

delberg, 1883); Pisynos, *Die Tugendlehre des Plotin* (Leipzig, 1895).

PLOUG, plô. PARMO CARL (1813-94). A Danish poet and politician, born in Kolding. As editor of the *Fædreland* (the Fatherland) from 1841 to 1881, he used his pen to uphold the national Scandinavian spirit. He was a member of the constitutional convention in 1848-49, and from 1854 to 1857 of the Folkething. His popular student songs were published under a pen-name as *Poul Rytters Viser og Vers* (1847), and in 1861 his complete poems, *Samlede Digte*, appeared. His later volumes of verse, erotic and patriotic, were *Nyete Sange og Digte* (1869), *Nye Digte* (1883), and the posthumous *Eftertætte Digte* (1895).

PLOVER (OF. *plover*, Fr. *pluvier*, from ML. *plurarius*, plover, from Lat. *pluvia*, rain, from *pluere*, to rain; connected with Gk. πλείν, *plein*, Skt. *plu*, *pru*, to swim, and ultimately with Lith. *plusti*, Lett. *pludet*, AS. *fleostan*, OHG. *fliozzan*, Ger. *fliessen*, to flow; so called because the bird appears during the rainy season). A limicoline bird of the subfamily Charadriinæ, of the large shore-bird family Charadriidæ, having a bill somewhat like that of a pigeon, with a convex horny terminal portion, behind which it is contracted; the legs not very long, naked a little above the tarsal joint; the wings rather long and pointed, the first quill-feather the longest; and usually only three toes. The species are about 60 in number, found in every quarter of the globe, and many are migratory and of very wide range. They chiefly frequent low moist grounds, where they congregate in flocks, and feed on worms, insects, and the like, and some of them are table delicacies. The golden or yellow plover (*Charadrius dominicus*) is 11 inches long, blackish, speckled with yellow at the tips and edges of the feathers; the throat, breast, and belly black in summer, whitish in winter. It is a bird of passage in the United States, breeds in the far north, and winters in Central and South America, going even as far as Patagonia. Some account of its remarkable flights is given under MIGRATION OF ANIMALS. In the Eastern United States it is more common in fall than in spring. It makes an artless nest, little more than a slight depression of the ground, and lays four eggs. The parent birds show great anxiety for the protection of their young, and use various stratagems to divert the attention of an enemy. The ringed plover (*Ægialitis hiaticula*), a much smaller bird, is found in Greenland and the Arctic regions of America, but is most abundant in the northerly parts of the Old World. It occurs at almost all seasons on sandy and shingly flats, from which the sea retires at ebb-tide. It is often to be seen also on the banks of large rivers, lakes, and ponds. It is grayish-brown above, whitish beneath, with a collar of white round the neck, and below it a black—in winter, a brown—collar; the head marked with black and white; a white bar on the wing.

BEAK OF THE GOLDEN PLOVER.

In the United States six species exist, all

PLOVERS

1. WILSON'S PLOVER (*Ægialitis Wilsonia*).
2. KILDEER (*Ægialitis vociferus*).
3. AMERICAN GOLDEN PLOVER (*Charadrius Dominicus*).

4. BLACK-BELLIED PLOVER (*Charadrius squatarola*).
5. LAPWING (*Vanellus vanellus*).
6. EGYPTIAN SPUR-WINGED PLOVER (*Hylopterus spinosus*).

closely resembling the ringed plover, of which the semipalmated or 'ring-neck' (*Egialitis semipalmata*) is the American analogue. The largest and best known is the kildeer (q.v.). The piping plover (*Egialitis meloda*) is found along the Atlantic coast, and is notable for the musical quality of its notes. The snowy plover (*Egialitis nivosa*) is a handsome species found in the Southwestern United States. All of the ring-plovers lay their three or four eggs in a depression in the ground; the eggs vary in color from creamy-white to olive-drab, heavily marked with blackish-brown. In the Western United States occurs the mountain plover (q.v.), which differs from the others in the absence of any black belt or markings on the neutral surface. The 'beetle-head' or black-bellied plover (*Charadrius squatarola*) is a nearly cosmopolitan form, recognizable in any plumage by the small hind toe and the rounded scales on the front of the tarsus. It is nearly a foot long, and in full plumage is a very handsome bird, black and white contrasting in its plumage to make it notable. It breeds in the Arctic regions and winters in the tropics. The bird known to American sportsmen as the 'upland plover' is not a plover at all, but a sand-piper (*Bartramia longicauda*).

Several remarkable birds of this group belong in South America, Africa, and Australasia. One of these is the Egyptian 'spur-winged' plover (q.v.); see also CROCODILE-BIRD.) Another is the strange 'crook-billed plover' of New Zealand. (See WRYBILL.) Closely allied to them are the European and Asiatic 'lapwings,' and the South American 'teru-teru' (q.v.) of the widespread genus *Vanellus*. Consult: Dresser, *Birds of Europe* (London, 1881); Seebohm, *Birds of Asia* (ib., 1888); Buller, *Birds of New Zealand* (2d ed., ib., 1888); Shelley, *Birds of Egypt* (ib., 1872); Sharpe and Hudson, *Argentine Ornithology* (ib., 1888); Walsingham, "Shooting," in *Badminton Library* (ib., 1889); Elliot, *Shore Birds of North America* (New York, 1895); Lefringwell, *Shooting on Upland, Marsh, and Stream* (Chicago, 1890). See Plate of EGGS of WATER and GAME BIRDS; and Plate of PLOVERS.

PLOW, PLOWING (AS. *plōh*, OHG. *pfluoh*, Ger. *Pflug*, plow; connected with Longobardic *plorum*, and possibly with Gk. *γλωχιν*, *glōchin*, projecting point). In all countries where agriculture is in an advanced state, the first agricultural operation in order and importance is the breaking up of the soil by inverting the upper stratum of earth upon which the plants grow. Such an operation also buries and destroys weeds; leaves the surface clean, unencumbered, and in a condition favorable for weathering; increases the storage capacity of the soil for water; but also assists percolation and thus aids in drying and warming the soil.

To the unobservant, the plow seems a simple and even primitive tool; yet it is the product of slow evolution and much mechanical skill. The plow in primitive form probably antedates history. The Old Testament mentions plows shod with iron or bronze, but except in Western Europe and America little progress has been made in improving the implement since the time of Herodotus. One of the earliest types of plows is shown in Fig. 1; a type of the ordinary modern plow in its simple form in Fig. 2. As will be seen, the modern plow consists of several parts—

a beam, by which the plow is drawn, which may be of wood or metal; two handles, usually wood, for guiding. To the end of the beam a clevis or bridle is attached for convenience in hitching the team and regulating the depth and width of furrow, and near the outer end a small adjustable wheel (frequently omitted) for assisting in steadying the plow and regulating the depth of the furrow. Behind this is a coulter for cutting the furrow slice at the side. This coulter takes various forms—a miniature plow or jointer, a stout iron knife, or a revolving disk with sharp edge. Back of the coulter is the plow proper, consisting of a strong cast-iron frame (standard or sheath) firmly fastened to the beam and braced by the handles in rear. To this frame

FIG. 1. PRIMITIVE PLOW.

is attached a pointed share for cutting the furrow slice at the bottom, a mold-board for turning the furrow slice, and the land-side opposite the mold-board, which presses against the side of the furrows and helps to steady the plow.

The first patent for a plow is said to have been obtained by Joseph Foljamb in 1730, and Jethro Tull about this time invented a plow designed especially to pulverize the soil thoroughly, an idea embodied in modern plows of the best

FIG. 2. AMERICAN PLOW.

type. Figure 3 shows the Rotherham plow used in Holland at the beginning of the eighteenth century, and afterwards introduced into England.

In attempts to improve the plow the mold-board, which raises and turns the furrow slice and which appeared in the plows of the Netherlands during the seventeenth century, has probably received more attention than any other single part. Thomas Jefferson, who published his views in 1798, and James Small in 1802, were among the first to attempt to establish the proper lines of the mold-board upon a mathematical basis.

FIG. 3. EARLY DUTCH PLOW.

As determined by the shape of the mold-board, ordinary plows are of two main types, (1) 'sod-plows' with long sloping mold-board which turn a narrow, flat furrow without pulverizing the furrow slice, but which bury vegetation, manure, etc., effectually; and (2) the 'stubble

plows,' with short, steep overbanging mold-board, which break up the furrow slice and pulverize the soil. English plows are generally of the first type. The modern American plow is generally of the second type, although plows of the first type are made and used to a considerable extent for special purposes in America. It may be said to date from September 1, 1819, when Jethro

employed for water-furrowing, etc.; the hillside or swivel plow, which is provided with a reversible mold-board, so that the team may walk in the opposite direction, but always place the furrow against the one previously turned. Another special form of plow is the double-furrow or gang plow (Fig. 4), which consists of an iron frame, usually mounted on a wheel or wheels, carrying two or more plows, one set a little to the rear of the other, and at the distance it is desired the width of the furrow should be. The sulky plow (Fig. 5) has also come into extensive use, the object of such plows being to lessen friction and reduce the labor of the plowman. The draught of such plows, however, was found by Sanborn to be not materially less than that of the ordinary swing plow. The first patent for sulky plows in America was granted to H. Brown in 1844, but practical plows of this type were not made until about 1864, and the manufacture of such plows is still in a state of evolution, although numerous forms are found on the market. The disk plow (Fig. 6), which is a comparatively recent invention, is attracting wide attention on account of its effective work under certain conditions. The principal feature of this plow in its more perfect form is a tempered steel disk

FIG. 4. MOUNTED GANG PLOW.

Wood of Scipio, New York, took out a patent for an improved cast-iron plow having the mold-board (of pulverizing type), share, and land-side cast in three separate pieces so that they could be replaced by new parts when worn. Anderson found that 55 per cent. of the draught of the plow is consumed in cutting the furrow slice, 12 per cent. in turning it, and 33 per cent. by the sole and land-side. Since such a small percentage of the energy required in plowing is consumed by the mold-board, it would seem to be economy to make this of such form that it will disintegrate the furrow slice as completely as possible. Such breaking of the furrow slice makes it easier for the tillage implements following the plow to fine the soil thoroughly without disturbing the buried sod and vegetation. A further important advantage of the work of such plows is the increased opportunity afforded to the soil for weathering.

FIG. 6. DISK PLOW.

25 to 30 inches in diameter, and usually set at an angle to the furrow and to the surface so as to turn and pulverize the soil. It is kept from clogging and assisted in pulverizing the soil by an adjustable scraper. The disk is carried by a steel framework mounted on wheels and provided with a seat for the driver and levers for control and adjustment of the plow.

The idea of the use of engines and machinery to plow the ground seems to have originated with David Ramsey and Thomas Wildgosse in 1618, but the motive power they proposed to use is not made clear. Francis Moore in 1769 first attempted to use the steam-engine for this purpose. The history of practical steam plowing dates from the invention of Fowler, assisted by Smith, in 1854. The inventions along this line have included plans for engines traveling over the surface of the ground, drawing plows or other cultivating implements along with them; engines working on tramways, and drawing implements after them; engines moving along opposite headlands, and working implements between them by means of wire ropes and stationary engines driving implements also by means of wire ropes. The steam plows used most widely in England belong to two classes—double-engine and single-engine or 'direct' and 'round-about' (Figs. 7 and 8). Gang plows carried on wheels are usually employed in these systems, the plows being in two series facing in opposite directions

FIG. 5. SULKY PLOW.

There are numerous other kinds of plows used for special purposes, such as trench or ditching plows, which are made on the same principle as the common plow, but larger and stronger, so as to bring up a portion of the subsoil to the surface; or subsoil plows, which have no mold-board, and merely stir and break up the subsoil, thus facilitating drainage. These plows are not used so much as formerly. There are also double mold-board plows, which are merely common plows with a mold-board on each side, em-

and so arranged that when one series is in operation the other is elevated above the soil. The steam plows used in America are of the gang class drawn by a traction engine as shown in Fig. 9. Attention of American inventors has been directed mainly toward developing a cheap, light, and durable engine of suffi-

The time and manner of plowing will be determined by the special object to be attained. In soils more or less impervious to water it is advisable to plow to different depths at different seasons of the year in order to prevent the formation of hardpan, which occurs when plowing to the same depth for several seasons, due to the

FIG. 7. DOUBLE-ENGINE OR DIRECT METHOD OF STEAM PLOWING.

cient traction and adapted to different kinds of land. On the Western wheat ranches there has, according to Taylor, been "developed a special form of engine for plowing, harvesting, and similar work. These engines have assumed a tri-cycle form, the weight of the boiler and engine

pressure of the plow and the trampling of the teams. If the soil is very pervious it is sometimes desirable to promote this formation of hardpan to arrest a too rapid percolation of water. Plowing promotes aëration of the soil and nitrification (q.v.), and otherwise improves

FIG. 8. SINGLE-ENGINE OR ROUND-ABOUT METHOD OF STEAM PLOWING.

resting on two very high, wide tread wheels with a third wheel of castor type in front for easy steering. A high-pressure, force-draught boiler is used, and small, high-speed engines, developing from 40 to 80 horse-power. Such engines draw from 12 to 18 twelve-inch plows, and turn over 25 to 40 acres per day." A system using electricity on the trolley plan has been introduced in Germany with some success. It is claimed for the better systems of steam and electric plowing that they are cheaper and more efficient than the ordinary methods. This may be true where horses and feed are expensive, fuel cheap, and lands level and otherwise well suited to these systems, but that it is universally true remains to be demonstrated.

the physical and chemical condition of soils, resulting in increased productiveness. A deep tilled layer of soil is desirable, but this should be brought about gradually, since the plowing should not be so deep as to bring up raw subsoil. Plowing to a greater depth than 6 or 7 inches is rarely desirable. The time and manner of plowing will be determined by climatic conditions, character of soil, and kind of crop to be raised. Sod may be plowed wetter than stubble land. In midsummer and fall deep plowing is desirable, in early spring rather shallow plowing is usually best. Manures and similar material should not be turned under deeply in the spring. If there is danger of too rapid evaporation, surface tillage should follow very closely

after plowing. Fall-plowed land should generally be left rough. Unless the soil has very good natural drainage the plowed land should have open furrows from 10 to 15 paces apart. Thorough and deep plowing is most economically performed with a large sulky plow with three or more horses (Fig. 5), except when the fields are small.

ment as counsel for those of his own faith, Bishop Bonner being one. His present reputation, however, rests chiefly on a series of reports of trials, *Les Comentaires*, etc. (London, 1571; trans., Dublin, 1792; London, 1816), written in law French, made by him and extending over the entire period of his connection with the bar. They are valuable as a careful and clear record of early

FIG. 9. AMERICAN METHOD OF STEAM PLOWING.

(Springfield, 1901); King, *Physics of Agriculture* (Madison, 1901); Ardrey, *American Agricultural Implements* (Chicago, 1894); Missouri Experiment Station Bulletin No. 32, *Plows and Plowing* (Columbia, 1888); Utah Experiment Station Bulletin No. 2, *Plow Trials* (Logan, 1890); United States Census Report 1860, volume on Agriculture.

PLOW'DEN, EDMUND (1518-85). An English jurist. He was born at Plowden, Shropshire; studied at Cambridge for three years, and in 1538 entered the Middle Temple, where after several years of close application to legal studies he was called to the bar. He took an active part in public affairs, and was one of the council of the Marches of Wales in the first year of Queen Mary's reign, and later sat several times as a member in Parliament; he was one of the 39 who, in 1554-55, withdrew from Parliament because dissatisfied with its proceedings, and against whom the Attorney-General filed informations. Plowden defended his case, and the matter was dropped. Upon the death of Mary and the accession of Elizabeth, Plowden failed to receive any further political preferment because of his faithful adherence to the Roman Catholic Church; but he retained his reputation as the greatest lawyer of his day and a most fearlessly upright public man. During his early career he was twice a reader of the Middle Temple, and he was its treasurer at the time when its present fine library was begun. (See *INNS OF COURT*.) He frequently appeared in court against the Govern-

precedents, and for the light they throw upon early legal procedure and development. Besides these he wrote *Les Quares del Monsieur Plowden* (London, trans., 1662). Consult: Fuller, *The Worthies of England* (London, 1662); Granger, *Biographical History of England* (1824); Wallace, *The Reporters* (Boston, 1882); and such books as Strype, *Works*; Murdin, *State Papers*; Jones's *Index*, etc.

PLOWMAN'S TALE, THE. A rhyming ballad by an unknown poet, written about 1395, printed as a Canterbury tale in Thynne's second edition of Chaucer, 1542. It is a denunciation of Roman Catholicism in the story of a dispute heard by a plowman between a griffin (Rome) and a pelican (Lollardism).

PLOW MONDAY, or ROCK MONDAY. The name of the Monday after Twelfth Day, or the close of the Christmas holidays, when the work of the plow is supposed to start again. In England in some places the day is devoted to rustic sports. A plow is dragged from door to door by plowmen, who ask for contributions.

PLOYESHITI, plô-yësh'té, or **PLOESTI** (Rum. *Ploesci*). A town of Rumania, capital of the District of Prahova, 38 miles north of Bucharest (Map: Balkan Peninsula, F 2). It is advantageously situated in a petroleum-bearing district and is rapidly increasing in commercial importance. Its educational institutions include a lycée, a school of arts and crafts, an institution for teachers, and a commercial school. Ployeshiti is an important military centre. Population, in 1900, 42,687.

PLÜCKER, plük'ër, JULIUS (1801-68). A German mathematician and physicist, born at Elberfeld. After holding positions at the universities of Halle and Berlin he became professor of mathematics at Bonn (1836). Plücker produced works of very great importance in the field of analytic geometry. In his *Analytisch-geometrische Entwickelungen* (2 vols., 1828, 1834) he developed the dual relation between modern analysis and pure geometry. The *System der analytischen Geometrie* (1835) deals extensively with the classification of cubic curves. His *Theorie der algebraischen Curven* (1839) contains the famous 'six equations' relating to the singularities of higher plane curves. (See CURVE.) This was followed by his *System der Geometrie des Raumes in neuer analytischer Behandlung* (1846; 3d ed. 1852). From 1847 onward Plücker devoted his attention to physics, and he became professor of this science at Bonn. He devoted his attention especially to the magnetic properties of gases and fluids, to the electric luminosity of rarefied space, and to the phenomena of the spectroscope and the Geissler tubes. In 1865 Plücker once more turned his attention to mathematics and invented what is now called line geometry. He died before he had finished the publication of a work on this subject, containing his theory of 'complexes' and 'congruences' (see CONGRUENCE), but it was completed by his pupil and assistant, Klein, under the title *Neue Geometrie des Raumes gegründet auf die Betrachtung der geraden Linie als Raumelement* (1868-69). His scientific memoirs were published in the *Proceedings* of the Royal Society of Science at Göttingen. He was also a contributor to the *Philosophical Transactions* of the Royal Society. Among the papers contributed are: "On a New Geometry of Space" (1865, vol. 155); "On the Magnetic Induction of Crystals" (1858, vol. 148); "On the Spectra of Ignited Gases" (1865, vol. 155). Consult: Clebsch, *Zum Gedächtnis an J. Plücker* (Göttingen, 1872); Dronke, *Julius Plücker* (Bonn, 1871). His *Gesammelte Abhandlungen* have been published in two parts by the Royal Society of Göttingen (Leipzig, 1895-96).

PLUM (AS. *plūme*, *plyme*, OHG. *pflūmo*, *prūma*, Ger. *Pflaume*, from Lat. *prunum*, plum, *pruna*, plum-tree, from Gk. *πρῶνον*, *prounon*, *πρῶνον*, *prounnon*, plum, *πρῶνη*, *prounē*, *πρῶμηνη*, *proumnē*, plum-tree). Small trees or shrubs belonging to the genus *Prunus*, and extensively cultivated as orchard fruits in temperate regions. The fruit is distinguished from the peach, its near relative, by its smooth skin and unwrinkled stone. It is larger than the cherry and is further distinguished from it by the bloom covering it. There are three main groups of widely cultivated plums: (1) Domestic or European plum (*Prunus domestica*); (2) Japanese plum (*Prunus trifoliata*); and (3) native American plums, cultivated only in America having been derived largely by selection during the closing years of the nineteenth century from numerous native species, the most important of which are: Americana types, from *Prunus Americana*, commonly found from the Atlantic west to the Rocky Mountains and south to the Gulf; the Wild Goose or Hortulana types, from *Prunus hortulana*; and Chickasaw types, from *Prunus angustifolia*. The domestica varieties

were the first plums cultivated in the United States. They thrive in the regions north of Pennsylvania and west to the Great Lakes and on the Pacific Slope, where the American prune industry has reached its greatest development. The European plum (*Prunus domestica*) is native to Eastern Europe and West-Central Asia. Another plum native to Southern Europe and extensively grown as a stock is the myrobolan or cherry plum (*Prunus cerasifera*). There are but very few cultivated varieties of this species. The Japanese plums are native to China. They stand next in commercial importance to the European plums. Many varieties ripen much earlier than the European plums.

WILD PLUM (*Prunus Americana*).

The fruit is very firm and stands shipment well, and the trees are not so susceptible to black knot and the curculio. They were first introduced in America about 1870, and have rapidly become popular in the United States, where they can be grown much farther south than the European plums. There are many varieties of most of the above species of plums now in cultivation, and in addition a large number of named hybrids.

Plums true to variety are propagated usually by budding the seedlings in August or September. Whip grafting is used to some extent and has proved especially valuable in working plums on peach roots. They may also be top-worked in the same manner as apples. Plums, as a rule, do best in a deep rather heavy soil with an open subsoil. The domestica prefer a heavy clay soil, while the Japanese varieties and some of the hybrids may be grown on light sandy soils. Most varieties may be set in the orchard when one year from the bud or graft, but with the European plums two-year-old trees are preferred. Waugh and other investigators have shown that for all practical purposes native American plums and Japanese varieties are sterile to their own pollen and will not produce fruit unless the trees are mixed in the orchard with other varieties. Plums are set in the orchard about 15 feet apart each way. A few varieties require 20 feet each way. Pruning the plum is confined largely to the formation of the head during the first two or three years' growth in the orchard, and afterwards to removing dead and crossed branches. The plum orchard in America is usually plowed in early spring and kept well cultivated until the middle of summer, when it is seeded to some cover crop. In some of the Northwestern States mulching with straw, marsh hay, etc., has been found preferable to cultivation. A moderate amount of barnyard manure applied every second year has been found beneficial in the plum or-

chard, and wood ashes on soils deficient in potash and lime. Most varieties of plums tend regularly to overbear, and thinning has been found necessary to secure the finest fruit, especially with the American varieties. The plums are left to stand two or three inches apart. They are marketed as soon as they become well colored. In the United States the eight-pound grape basket makes one of the most satisfactory packages.

PLUM DISEASES. Plums and cherries are often attacked by the same fungi. Leaf blight or shot hole is due to the presence of one or both of two fungi, *Cylindrosporium padi* and *Septoria cerasina*, in the leaves, the symptoms being alike on both plum and cherry. Circular purplish spots one-eighth inch in diameter appear; later the tissues become brown and break out from the leaves, leaving holes as though made with shot. In severe cases the leaves turn yellow and the trees are defoliated. This disease can be prevented by spraying the trees with Bordeaux mixture at intervals of two weeks from the time the leaves appear until July. Another disease to which the plum and cherry are subject is the black knot or plum knot, due to *Plowrightia morbosa*, which appears as a serious pest only upon sour cherries and upon plums. When mature the black knots are rough wart-like excrescences upon the branches. At first they are yellowish in color, but soon become darker, the surfaces having a velvet-like appearance. This soon disappears and the knots grow still darker, in winter becoming black. The fungus is spread by its spores, which, lighting upon a branch in a crevice in the bark, soon infest the limb. It also remains alive during winter, the mycelium remaining in the twigs and branches. The infested branches should be cut and burned, and where knots are on large limbs or upon the tree trunks they may be cut out or painted with kerosene. After careful pruning the trees may be sprayed during the growing season with any good fungicide (q.v.) to prevent any spores that may find lodgment from germinating. A disease peculiar to the plum is that known as plum pockets, due to attacks of *Exoascus pruni*. The fruit is infected soon after blossoming and begins to swell until it becomes an inch or two in length. At first the 'pocket' is light in color, but finally becomes dark brown or black, and the fruit falls to the ground. It is usually hollow and bladdery in appearance, hence the name. The walls of the fruit are thickened, but it contains no stone or pit. The leaves and stems are also attacked, the affected parts assuming swollen distorted shapes. This disease can be controlled to some extent by thorough use of fungicides. Applications should be made before the buds have opened and again just after the flowers have fallen.

For an account of plum culture in America and descriptions of the varieties grown, consult: Waugh, *Plums and Plum Culture* (New York, 1901); Goff, *Culture of Native Plums in the Northwest* (Wisconsin Agricultural Experiment Station Bulletins 63 and 87); Bailey, *The Cultivated Native Plums and Cherries* (New York, Cornell Experiment Station Bulletin 38); id., *The Japanese Plums in America* (ib., Bulletins 62, 106, 139, and 175); Waugh, *The Pollination of Plums and Hybrid Plums* (Vermont Experiment Station Bulletins 53, 67, and 75, and references for 1896-1901). See Colored Plate of DRUPES.

PLUM, BEACH (*Prunus maritima*). A species of plum growing upon the Atlantic coast from New Brunswick to Virginia, and appearing again in Michigan along the lake. As a class beach plums are of little value for their fruit, a single named variety only being listed. For ornament, however, the group has greater merit, as the blossoms are rather large and showy and the fruits are of high color when ripe.

PLUM, DATE. See PERSIMMON.

PLUMBAGO. See GRAPHITE.

PLUMBING (from *plumb*, from OF. *plomb*, *plom*, Fr. *plomb*, from Lat. *plumbum*, lead). In its broadest sense, the pipes and fixtures within houses or other buildings used to supply water, gas, and heat, including in the latter steam and hot water, and also the pipes used to remove liquid wastes from buildings; or the mechanic art of providing the pipes and fixtures named. A more restricted and more common use of the term includes only the water supply and house drainage systems, leaving gas fitting and steam and hot water fitting in two separate classes. (See GAS, ILLUMINATING; and HEATING AND VENTILATION.) The early plumber worked in lead, providing pipe systems for water supply, applying sheet lead for roof coverings and setting window glass. Later lead pipe was adopted for other purposes, notably for gas services, and for removing household wastes. Hence the name plumber, originally applied to a worker in lead. Later yet lead was largely replaced by other metals. (See PIPES.) To-day the plumber and the gas, steam, and hot water fitter employ lead, wrought-iron, brass, copper, and the various kinds of plated pipe, including nickel-plated goods. Vitrified clay or sewer pipe is not used in good plumbing, at least not in buildings, but vitrified pipe is almost wholly used to connect the house and street sewerage systems.

WATER SUPPLY. The pipe leading from the street main to the building is called the house

KITCHEN BOILER AND CONNECTIONS.

connection or *service pipe* and is frequently laid, at least as far as the curb or sidewalk line, by the water department. The service pipe, and the water pipe system within the house as well, may

be of lead or wrought iron; or if the building be large, the main piping may be of cast iron. In highly finished, expensive work, brass or nickel-plated pipe is sometimes used, and copper may be employed for hot-water piping. As some waters attack and decompose lead and give rise to lead poisoning, the materials for services and house piping should be chosen accordingly. (See SANITATION and WATER-WORKS.) A valve at the sidewalk enables the water department to turn on or shut off the water to the consumer at will, and another valve, just inside the cellar wall, permits the householder to control the house supply from that point also. The water

butler's pantry, and, in large houses and semi-public and public buildings in various other places. Most commonly they are of iron, and have hot and cold water. *Laundry tubs* are placed in a separate room or in the kitchen, and consist of two or more rectangular compartments, with the front side sloping, provided with hot and cold water, and composed of soapstone, artificial stone, cement, iron, or other material, with or without hinged wooden covers. The chief essential in the material for laundry tubs is lack of porosity, on which account wood, with its high absorbing quality, is unsuitable. *Set wash bowls* are provided in bathrooms and lav-

WATER SUPPLY AND DRAINAGE OF A DWELLING.

meter, if employed, is generally placed just inside the latter shut-off valve. Except in the smaller and cheaper houses the water piping is mostly in duplicate, one set of pipes being for hot and one for cold water. The water is heated by circulating through a pipe or a *water back* at the rear of the kitchen range, from which it goes for storage to the kitchen or range boiler. These boilers are made of wrought iron, steel, or copper, with riveted joints, and should be tested to withstand a high pressure. When the water supply is liable to be inadequate at times, or when the direct pressure is too heavy for safety to the plumbing, a *tank* is provided in the upper part of the building. Great care is necessary to secure and maintain water-tightness. Tanks must be provided with automatic valves to insure a constant supply therein, and to prevent water going to the tanks when full; also with overflow or waste pipes.

FIXTURES. The various faucets, sinks, and other similar appliances connected with a plumbing system are called fixtures. *Faucets, cocks, or valves* are provided at each place where water is to be drawn. (See VALVES.) It is important that these should be of high grade to prevent leakage. *Sinks* are provided in the kitchen, the

atories, in the private rooms of hotels, and sometimes, but less frequently than formerly, in the sleeping rooms of private dwellings. Probably they are most commonly of marble, but cast iron and steel, both painted and enameled, and porcelain are also employed. *Bathtubs* are of polished sheet copper, formed on wood, of solid copper, of painted or enameled cast iron, and of porcelain. *Shower baths, sitz baths, and foot baths* are for the special purposes indicated. *Water-closets*, so called because matter deposited into them is flushed out by a discharge of water, are most commonly of glazed earthenware, although in cheap work cast iron is sometimes used. The old-fashioned pan water-closet was one of the most unsanitary of all plumbing fixtures, and thousands are still in use. It consisted of a metal pan, hinged so as to drop downward and discharge its contents into the pipe with which it was connected. It was a centre for filth and bad odors, and is no longer tolerated where sanitary principles are understood. The valve and plunger closets, operated as indicated by their names, were but little better, and are also out of date. Most of the approved forms of water-closets now in use depend for their action upon the sudden discharge of a few gallons

of water, generally from a tank located above the closet. The discharge is generally effected by pulling a hanging chain attached to a lever and valve, but in the case of closets in public places the tanks may discharge automatically. Recently, however, attachments have been introduced by flushing water-closets without the use

lighted, ventilated, and warmed. *Sill or hose cocks* are faucets or valves, with a provision for attaching hose, provided at convenient points for sprinkling lawns and washing sidewalks. In some localities they, or the hose so used, are called *pave washes*.

HOUSE SEWERAGE or DRAINAGE includes everything required to remove fouled water from the house to the sewer. The pipes from each separate fixture are known as *waste pipes*; they run to one or more *soil pipes*, the soil pipe being the vertical run of pipe from the highest fixture to the cellar; the *house drain* extends from the foot of the soil pipe to a point near the cellar wall, and the *house sewer* from the latter point to the street sewer. Waste pipes, particularly short runs from washbowls and minor fixtures, may be of lead, but, generally speaking, cast or wrought iron is preferable for important wastes. All soil pipes and the house drain should also be of cast iron. Heavy pipe should be used throughout. The house sewer should be of extra heavy iron through and a short distance beyond the foundation, after which vitrified clay is permissible. All soil and waste pipes should be carried up through the roof. Traps are placed below each fixture and a main trap is generally set just inside the cellar wall. All main traps should have *fresh air inlets* or a pipe extending from the inner end of the trap to the outer air. This provides for a circulation of air through the house drain and soil pipe. An increasing number of sanitary engineers favor the omission of the main trap, thus insuring a thorough ventilation of the house and street sewerage system through the numerous soil pipes at one extremity and the street manholes at the other. The object of a trap is to prevent foul air from the house or street sewerage system from entering the house. To this end the simplest and most common practice is to form a water seal by making a bend in the pipe shaped like the letter U or like the letter S, the former being called a U-trap and the latter an S-trap. *Bell traps* are formed by inverting a bell or cup over the upper and open end of a pipe, the whole being so adjusted that the edge

TYPES OF WATER-CLOSETS.

of a tank, the water supply being controlled by a valve, operated by a short lever, near the closet seat. In either case the water thus liberated displaces the water previously standing in the bowl or hopper of the closet or else sets it in motion by siphonic action, carrying the wastes with it. By this means the closet is kept fairly clean, particularly the most exposed portions, and the parts not thoroughly clean are always wet. There is an almost endless variety of closets. Some of the most approved patterns are shown in section by the accompanying illustrations. Water-closet *flush tanks* are generally of wood, lined with copper, and provided with a float valve, a water supply, and a flush pipe. The closet seat is of hard wood. *Urinals* are provided in public places, and consist of either bowls or vertical slabs of non-porous material, inclosed in stalls and provided with flushing water. *Latrines* are a series of water-closet stalls connected with a long trough or common flushing chamber below. They are chiefly employed for barracks and institutions. The terms *bathroom* and *water-closet* are frequently employed to designate the compartments which contain a bathtub, water-closet, and set washbowl. Such rooms should always open to the outer air, or at least into a large air-shaft, and be well

TYPES OF TRAPS.

of the pipe is always submerged. *Grease traps* may be described as enlargements on waste pipes to retain grease instead of allowing it to pass on and clog the sewers. They are most commonly used on the waste or drain pipes of large

kitchens. *Vent pipes* were formerly run from the back of each trap to a connection with the outer air, to give a back air pressure on the trap and lessen the danger from siphonage. Obviously, such a pipe from every trap greatly complicates a plumbing system, and trap vents are now omitted on much of the best work in the United States. Regarding the omission of both main traps and trap vents it should be said that there is little need for them on well designed and built house and street sewerage systems, because the wastes are speedily removed and in well-ventilated sewers the air is comparatively good.

GENERAL CONSIDERATIONS. Simplicity, accessibility, a high grade of material throughout, heavy weights for pipes, and good workmanship are the essentials of plumbing. To secure these, plumbing should be designed only by the most competent sanitary engineers, and should be under the rigid supervision of efficient municipal inspectors. All plans for plumbing should be filed with the plumbing inspector or health department. The hydraulic pressure test should be applied when the rough plumbing has been completed, and the smoke or peppermint test when the fixtures are set.

BIBLIOGRAPHY. Gerhard, *Sanitary Engineering of Buildings* (New York, 1899), and *House Drainage and Sanitary Plumbing* (New York, 1882); Chapin's *Municipal Sanitation in the United States* (Providence, 1901) is valuable on account of its extracts and summaries based on plumbing ordinances. See GAS; HEATING AND VENTILATION; SEWERAGE; WATER-WORKS.

PLUM CURCULIO. A weevil (*Conotrachelus nenuphar*) especially injurious to the plum. See PLUM INSECTS.

PLUME, CAPTAIN. The leading character in Farquhar's comedy *The Recruiting Officer*; a dashing soldier who marries Sylvia, an heiress, and leaves the service.

PLUMED KNIGHT. A nickname of James G. Blaine, first given by Colonel Robert G. Ingersoll in 1876, in nominating Blaine for the chairmanship of the Republican convention. The phrase became a favorite nickname, and Blaine was thereafter regularly depicted in cartoons under this character.

PLUME MOTH. A moth of the family Pterophoridae, a group of wide distribution and probably numerous in species, but the insects are very small and very delicate and are seldom collected. The wings are usually divided after the fashion of a hand into fingers, so as to form feathers. The hind wings are more completely divided than the front, which sometimes are not parted more than once or twice. There is much variety in the habits of the larvæ and pupæ; some are covered with hair and live exposed upon leaves, and some have hairy pupæ, while in some cases there is a slight cocoon. Some larvæ are curiously armed and protectively colored. About 65 species are known in the United States. One of the commonest forms (*Oxyptilus perisceledactylus*) is yellowish-brown in color. The larvæ hatch in the spring and feed upon the leaves of the grape, of which they fasten several together. The caterpillars live either singly or in companies of two or three in such habitations, changing to pupæ early in June.

The species of the family Orneodidae are also included in the term 'plume moth,' since the

wings are divided as in the Pterophoridae, but much more greatly divided, each wing being split into six plumes. Only one species (*Orneodes hexadactyla*) occurs in the United States, and it is also found in Europe and Canada.

PLUM'ER, WILLIAM SWAN (1802-80). An American clergyman. He was born at Griersburg (now Darlington), Beaver County, Pa., graduated from Washington College, Virginia, in 1822, and studied divinity at Princeton Theological Seminary. In 1826 he was licensed to preach, receiving his ordination as evangelist the following year, and from the beginning of his licentiate till 1829 he labored as evangelist in Virginia and in North Carolina. He then became pastor of the Tabb Street Church, Petersburg, Pennsylvania, and held successive pastorates at Richmond, Baltimore, and Allegheny. From 1865 to 1867 he was pastor of the Second Church, Pottsville, Pa. For eight years succeeding 1837 he owned and edited *The Watchman of the South* (Richmond, Va.). From 1854 to 1862 he held a professorship in the Western Theological Seminary, Allegheny, Pa., and from 1867 to 1880 in the Theological Seminary at Columbia, S. C. He published over twenty-five volumes, including commentaries on the Psalms, Romans, and Hebrews, and sermons, tracts, and pamphlets in large number.

PLUMIER, plu'myá', CHARLES (1646-1704). A distinguished French botanist, born at Marseilles. He studied botany under the celebrated Joseph de Tournefort (q.v.), and in 1689 visited the West Indies. On his return he published *Description des plantes de l'Amérique*, with numerous plates (1693). At the King's request, he twice again visited North America in 1693 and 1695. In 1703 appeared his *Nova Plantarum Americanarum Genera*. When about to sail the fourth time for America, in order to investigate the subject of Peruvian bark (cinchona), he died at Cadiz. A work that is still often consulted is his treatise on the ferns of America, which appeared in the year after his death. It contains 172 engraved plates. He wrote extensively in miscellaneous publications on the plants, birds, and fishes of America. A genus of South American plants, *Plumeria*, several of which are cultivated for their fragrance, was named by Tournefort in his honor. See Haller's *Bibliotheca Botanica*.

PLUM INSECTS. The most notable of the insects which damage the plum in the United States is the plum curculio (*Conotrachelus nenuphar*), a species which for many years has destroyed almost the entire crop over large sections of the country. It is a small, rough, grayish or blackish beetle, about one-fifth of an inch long, with a black, shining hump on the middle of each wing case. The female lays her eggs in the young fruit shortly after they are formed, making with her long snout a small cut through the skin, running in the snout to a depth of about one-sixteenth of an inch. In this cavity the egg is placed. She then cuts a crescent-shaped slit through the skin in front of the hole so as to undermine the egg and leave it in a flap, the object being apparently to cause the piece around the egg to wilt and thus to prevent the growing fruit from crushing the egg. The larva is a white, footless grub which feeds upon the flesh of the fruit, feeding for the most part about the

stone. It reaches full growth in from three to five weeks. The fruit meantime has become diseased, and has fallen prematurely to the ground. The larva leaves the fallen fruit, enters the ground to a depth of from four to six inches, and transforms to pupa in an earthen cell, issuing in from three to six weeks in the adult condition. The insect is single-brooded and hibernates as an adult. The beetles emerge from hibernation when the trees are about to blossom, feed for some time by puncturing the twigs and buds, and lay their eggs in the fruit soon after it is formed. The best remedies consist in spraying the trees with an arsenical mixture during the feeding-time of the beetles, and afterwards in jarring them, causing the beetles to fall from the branches, when they are caught in cloth receptacles and destroyed. This jarring method is carried on with great success in some of the largest orchards in the country.

PLUM CURCULIO (*Conotrachelus nenuphar*) AND ITS WORK. a, Adult beetle; b, a young plum attacked by the larva; c, cherry affected by the larva.

Very few other insects are specifically connected with the plum. The larva of one of the sphinx moths (*Sphinx drupiferarum*) feeds upon the foliage, and a number of other species are found more or less abundantly eating the leaves. None of them, however, are ever sufficiently abundant to cause marked damage. As mentioned under PEACH INSECTS, the peach-tree borer sometimes attacks the trunks of plum trees. Another weevil occasionally damages the fruit, and this species, the 'plum gouger' (*Coccotorus scutellaris*), is especially abundant in parts of the West. It appears in the spring, about the same time as the plum curculio, but, instead of cutting a crescent-shaped flap, bores a round hole in the fruit like the puncture of a pin. The larva, instead of feeding around the stone of the fruit, works its way through the soft shell of the stone and feeds upon the kernel.

Consult Saunders, *Insects Injurious to Fruits* (Philadelphia, 1889).

PLUMMER, CALEB. A poor old toy-maker in Dickens's *Crieket on the Hearth*, who pretends to his blind daughter Bertha that he is young and happy, and that their wretched home is a palace.

PLUMPTRE, plümp'trê, EDWARD HAYES (1821-91). An English scholar. He was born in London, August 6, 1821; educated at University College, Oxford; became fellow of Brasenose in 1844; was chaplain at King's College, London, 1847-68; professor of pastoral theology there, 1853-63; professor of the exegesis of the New Testament, 1864-81; assistant preacher at Lincoln's Inn, 1851-58; prebendary of Saint Paul's, 1863-81; Boyle lecturer, 1866; became rector of Pluckley, 1869, and vicar of Bickley, 1873; was one of the Old Testament company of revisers

appointed by Convocation, 1869-74; became Dean of Wells, 1881. Besides volumes of verses, *Lazarus and Other Poems* (1864), *Master and Scholar* (1866), *Things New and Old* (1884), he published poetical translations of Sophocles (1865), Æschylus (1868), and of Dante's *Divina commedia* and *Canzoniere* (1886-87), the latter particularly helpful in its notes. In prose, besides contributions to various commentaries, dictionaries, and periodicals, he wrote *Christ and Christendom* (1867); *Biblical Studies* (1870); *Movements in Religious Thought: Romanism, Protestantism, and Agnosticism* (1879); *The Spirits in Prison* (1884); *Life and Letters of Bishop Ken* (1888); and *Wells Cathedral and Its Deans* (1888). He died in Wells, February 1, 1891.

PLUNK'ET, WILLIAM CONYNGHAM (1765-1854). A British advocate, orator, and statesman, born at Enniskillen, Ireland. He graduated at Dublin University in 1784, studied law in London, was called to the bar in Ireland (1787), and made King's counsel ten years later. He sat in the Irish Parliament for the last two years of its existence (1789-1800), and was denounced as a renegade when he became Solicitor-General (1803). Attorney-General for Ireland in Pitt's Government (1805), he was elected in 1807, and sat again in 1812-22 in the English House of Commons, where he made his mark as the most eloquent Protestant pleader for Catholic emancipation. Once more Attorney-General for Ireland (1822), he became a peer and Chief Justice (1827) and was Lord Chancellor of Ireland from 1830 until 1841, when he retired. Consult the memoir by F. Douglass How (New York, 1901).

PLURALISM (from *plural*, OF. *plurel*, Fr. *pluriel*, from Lat. *pluralis*, relating to many, from *plus*, OLat. *pleor*, more; connected with Gk. *πλεων*, *pleiōn*, more, *πολυς*, *polys*, much, many, Skt. *puru*, OPers. *paru*, OIr. *il*, Goth., OHG. *filu*, Ger. *viel*, AS. *fedu*, archaic Eng. *feel*, many, and ultimately with Eng. *full*). In canon law, the possession by the same person of two or more ecclesiastical offices, whether of dignity or of emolument. Pluralism has been held unlawful from the earliest times, and is forbidden by many ancient councils, as Chalcedon (451) and the second of Nicea (787), on the ground of the impossibility, in ordinary cases, of the same individual adequately discharging the duties of more than one office. The rule by which dispensations from the law of residence are to be regulated, as well as the penalties for its violation, whether on the part of the patron or on that of the recipient, have formed the subject of frequent legislation. In general, it may be said that the canon law regards as incompatible (1) two benefices each having the cure of souls; (2) two 'dignities'; (3) a 'dignity' and a cure of souls; (4) a cure of souls and a simple benefice requiring residence. In other cases than these the Pope is held to have the power of dispensing. Although a constant effort was made to prevent abuse, the evasions of the law were formerly frequent, especially for noble or learned persons, but now are very rare in the Roman Catholic Church. The English law, before the Reformation, in the main coincided with the canon law, and the legislation of Henry VIII. preserved the same general spirit, only substituting the dispensing power of the

Crown for that of the Pope. Consult: Schulte, *Lehrbuch des katholischen und evangelischen Kirchenrechts* (Giessen, 1886); for England, *The Statutes Revised*, vol. viii. (London, 1894).

PLURALISM. In philosophy, a term used to designate any theory that states the universe in terms of more than one ultimate principle. Its antonym is monism (q.v.), when used in the stricter sense.

PLUSH (Fr. *pluche, peluche*, plush, shag, from Lat. *pilus*, hair). A variety of woven cloth, having a long shaggy pile on the upper surface. Although woven like velvet, it differs from it in the greater length of the pile, and in its not being clipped or shorn to a uniform length. Formerly it was made of a double warp, one thread being usually double worsted yarn, the other, intended to form the pile, of goat's hair, and the filling of worsted; occasionally only worsted was used. Now it is made very extensively of silk and cotton, the silk taking the place of the goat's hair to form the pile. This silk plush is the material used for making gentlemen's hats, instead of beaver-hair, as formerly. It is also worked in colored silks, for many articles of ladies' attire. A variety made of mohair is much used for upholstery. Recently the Tussah silk, a wild silk of India, has been extensively used in the manufacture of plush. See WEAVINGS.

PLUTARCH (Gk. *πλούταρχος, Ploutarchos*) (c.46-c.125 A.D.). An encyclopædic writer and a charming type of the Greek gentleman and scholar of Roman times. He was born at Chæronea, in Bœotia, the country of Hesiod and Pindar, to whom he often alludes. His writings introduce us to a pleasant circle of kinsmen and friends, his grandfather Lamprias, his father, brother, and four sons, his wife, Timoxena, to whom he addresses a beautiful 'consolation' on the death of their little daughter, his Roman friends, Sossius Senecio, Metrius Florus, and Junius Arulenus Rusticus. His biography must be collected from his works. He was a student at Athens at the time of Nero's visit to Greece, A.D. 66. Later he traveled in Greece, Egypt, and Italy. He visited Rome more than once, and remained there for some time in the reign of Vespasian, enjoying the friendship of prominent men, lecturing on moral philosophy and gathering the materials for his historical works. Real mastery of the Latin language and genuine insight into Roman institutions he never attained. He established himself for the last of his life at Chæronea, paying frequent visits to Athens, and to Delphi, where he exercised priestly functions. At Chæronea he held the office of archon and that of building inspector, recording his experiences perhaps in the treatise on the precepts of government and the essay on the question whether an old man ought to take part in politics. Greek moral philosophy being at that time the best substitute for religion, he became to many friends and young people a guide, philosopher, spiritual director, and physician of the soul, a rôle which a generation earlier Seneca had assumed with more self-consciousness and display at Rome. He recalled old memories of Rome and Athens in his 'table talk.' He wrote out his old lectures and gave new ones to the young people of an informal school that gathered about him. He composed dialogues in the manner of Cicero rather than of Plato. He continued his historical studies and

published his parallel *Lives* of Greeks and Romans. These, the best known of his writings, have been called 'the food of great souls,' because of their power to kindle emulation in youth, and the enormous influence which, through Amyot, Montaigne, and Shakespeare, they have exercised upon modern literature. Forty-six of them are extant, arranged in twenty-two sets. They cover all classical antiquity from Theseus-Romulus and Lycurgus-Numa to Demosthenes-Cicero and Alexander-Cæsar. They were not composed in the order of chronology or of their present arrangement. There are in addition four single biographies. The formal comparisons that follow most of the pairs are often somewhat forced. They stirred Shakespeare's sense of humor and provoked the delightful parody of Captain Fluellen's comparison of King Henry to Alexander on the basis of the resemblance of Macedon to Monmouth. They may be spurious, as the comparison was a recognized form of rhetorical exercitation. The *Lives* are avowedly character sketches with a moral, rather than severe historical studies. But they belong to the small category of the world's books which are read by all educated men, not merely consulted by scholars, and whose influence spreads in ever widening circles. Our knowledge of antiquity owes more to Plutarch than to any other one writer, and in the loss of his sources it is hardly necessary to add that the *Lives* become our primary authority for countless facts of history.

Hardly less interesting, though less known than the *Lives*, are the multifarious discursive or didactic essays and dialogues (some of them spurious) grouped under the title of *Moralia*. These comprise: The nine books of Table Talk or Symposiaca, a curious illustration of the playful pedantry that was accounted good conversation in later Græco-Roman cultured circles; edifying moral disquisitions enlivened by anecdote and quotation on such topics as "How a Young Man Ought to Read Poetry," "How to Distinguish a Flatterer from a Friend," "On Exile," "On Superstition," "Rules for the Care of the Health," "Advice to the Married," etc.; more elaborate essays or dialogues on religious or philosophical topics—"The Banquet of the Seven Wise Men," "On Isis and Osiris," a chief source of our knowledge of Egyptian religion; "On the Failure of the Oracles," "On the Genius of Socrates," "On the Contradictions of the Stoics," "On the Creation of the World Soul in Plato's *Timæus*." Plutarch's intimate knowledge of Plato lends a certain unity and seriousness of tone to all this discursive literary productivity. He was widely read also in the literature of the Stoics and Epicureans, but mainly to refute them when they diverged from Plato. His religion, too, if we make allowance for the temper of the age and for suggestions derived from later philosophies, is best characterized as a mild, vague Platonic theism. Literal interpreters, insisting on the doctrine of demons and the allegorical mysticism, exaggerate his credulity and superstition. As a true Platonist, he is greatly concerned for edification and shrinks from shocking any genuine religious faith. Hellenic patriotism required him to deal gently with Greek polytheism and the Greek oracles. He makes extensive and fantastic use of the allegorical methods of the Stoics and Philo for the reconciliation of the philosophy with both Hellenic and barbarian

myths. But the method in his hands is often obviously a mere exercise of literary ingenuity. And in the final test he will be found, like all true Platonists, to affirm little if any rigid dogma, and to make no concessions to concrete superstition.

Plutarch's style is that of an intelligent widely read man, familiar with the vocabulary of philosophy and the sciences, and more concerned for his matter than his manner. He does not affect Attic purism, and the tawdry rhetoric of his age has no attractions for him. He died somewhere between A.D. 120 and 130.

BIBLIOGRAPHY. The entire text may be found in the Teubner series, and also in the Didot *Bibliotheca* with Latin translation. Wyttenbach's unfinished 16 volume edition of the *Moralia* with *Index Græcitas* (Oxford, 1795-1830) is indispensable to the student. Gréard's *De la morale de Plutarque* (Paris, 1866) is a readable study. Volkmann's *Leben, Schriften und Philosophie des Plutarch* (Berlin, 1873) is scholarly and exhaustive. See also, Trench, *A Popular Introduction to Plutarch* (London, 1873), and the account in the last volume (on the Provinces) of Mommsen's *History of Rome*. The so-called Dryden's translation of the *Lives* revised in five volumes by A. H. Clough is a stock book. North's version from the French of Amyot was reëdited by Wyndham in 1895. The *Moralia* may be read in the traditional translation revised by W. W. Goodwin (Boston, 1874-78).

PLUTEUS, plū'té-ūs (Lat., parapet, partition, penthouse. In classical architecture, a section of a parapet or a slab filling up the space between two columns; an inclosure around an altar or other low screen.

PLUTO (Lat., from Gk. Πλούτος, *Ploutōn*, wealth). In Greek mythology, the god of riches, son of Demeter and Iasion. According to the legend Zeus blinded him so that he might not be able to discriminate in his gifts, and in the *Plutus* of Aristophanes he appears as a blind old man. In art, however, he was usually represented as a child, and in the arms of some goddess, such as Tyche (Fortune) or Athena Ergane (the Worker) or Eirene (Peace). A copy of the celebrated statue of Eirene and the infant Plutus by the Athenian artist Cephisodotus is to be found in the so-called Leucothea of the Glyptothek in Munich.

PLUTO (Lat., from Gk. Πλούτων, *Ploutōn*, from πλούτος, *ploutos*, wealth). The Roman name for the Greek god of the lower world, properly HADES. Two conceptions may be distinguished. One chiefly prominent in poetry represents him as the grim and implacable ruler beneath the earth; an enemy of all life, invisible, terrible, not to be appeased by sacrifice or prayer. His kingdom, though provided with palace and all else that belong to his state, is gloomy and full of horrors, while from it none ever escape. The other conception seems rather found in some aspects of his cult and in popular belief. It is best expressed through his name Pluto, and considers the ruler of the lower world as the owner and bestower of the products which are hidden in his kingdom, especially of the grain. This aspect seems prominent in the cult of Eleusis, and it is significant that the name Pluto first occurs in Attic poets of the fifth century B.C. Naturally Hades is not prominent in the myths. He was

considered a son of Cronos and brother of Zeus and Poseidon, to whom the depths of the earth and the kingdom of the dead were assigned after the overthrow of the Titans. From the Cyclops he received his cap of invisibility, which belongs to him as the thunderbolt to Zeus and the trident to Poseidon. In his chariot he suddenly burst from the earth and carried off Persephone (see CERES), who became his queen and regularly shared his cult. It should be noted, however, that this cult is directed to Pluto, and to the milder aspect of the god. So far as can be seen only at Pylas in Elis was there a sanctuary of Hades. This was only opened once a year, and then could only be entered by the priest. In art Hades is not a frequent figure, and no distinct type was developed to distinguish him. In general he differs from Zeus only in his expression, which is dark and stern, with his hair hanging heavily over his brows. He is also fully and even heavily draped. Of course in such scenes as the rape of Persephone modifications appear, and sometimes a wolf's head helmet seems to represent the cap of invisibility.

In Rome the worship of Dis Pater and Proserpina was introduced in B.C. 249 in consequence of various omens, and games were held on three nights in the Campus Martius, accompanied by the sacrifice of black cattle. These games, according to the vow, were repeated in B.C. 146, and later were modified by Augustus. The place where the sacrifices were offered was called *Tarentum*, and the altar was twenty feet below the level of the ground and only exposed to view on these occasions. Proserpina may have been an Italian goddess, but this joint cult is certainly of purely Greek origin, and almost certainly borrowed from Tarentum.

PLUTO MONKEY. A West African monkey (*Cercopithecus Pluto*), one of the guenons of Angola, which is distinguished by the reddish-black color of the under parts and generally dark fur. The forehead has a white band and the cheeks bear bushy gray whiskers.

PLUTONIC ROCKS (from Lat. *Pluto*, god of the lower world). The name given to those igneous rocks which have consolidated at considerable depths in the earth and have subsequently been brought to the surface by the denudation and removal of the overlying strata. As a class they are contrasted with the volcanic rocks which have solidified at or near the surface. Most of the coarse-grained igneous rocks, especially granites, are of plutonic origin.

PLUVIOSE, plū vē óz' (Fr., rainy). The name given to the fifth month of the French Republican calendar, beginning on January 20th, 21st, or 22d and ending on February 19th, 20th, or 21st.

PLUVIUS. An epithet of Jupiter as the giver of rain.

PLYMLEY, PETER. An assumed name under which Sydney Smith published a series of vigorous letters in defense of Catholic emancipation (1807-08).

PLYMOUTH, plīm'úth. An important seaport, Parliamentary and county borough, in the southwest of Devonshire, England, 231 miles west-southwest of London (Map: England, B 6). It stands in the Bight of Plymouth Sound between the estuaries of the Plym and Tamar. To

the west is Stonehouse, a township and coast-guard station, and still farther west is Devonport (q.v.), the great naval and military station. United by continuous lines of houses, they form an aggregation known as 'The Three Towns,' which constitutes one of the most important ports in England. Plymouth proper, which covers an area of one square mile, may be called the city, and Devonport the west end; while Stonehouse is an intermediate district, containing chiefly factories, barracks, victualing yards, hospitals, and other institutions. Plymouth extends from Mill Bay on the west to the mouth of the Plym on the east. Its site is somewhat rugged and uneven; an eminence forming the suburbs runs along its northern side, and another eminence, partly occupied by the citadel, fronts the Sound. The chief buildings are the Royal Hotel, comprising an immense inn, assembly-rooms, a theatre, and the athenaeum; the public library, containing in its Cottonian collection 300 sketches by the old Italian masters; Saint Andrew's Church, the tower of which dates from 1490; and Charles Church (1646-58), dedicated to 'Saint Charles the Martyr.' There are several important educational establishments, some of which are endowed, and many charitable institutions. The Guildhall and municipal buildings form a group of handsome Gothic buildings. The city contains an arsenal, a dock-yard, and other Government buildings, and a marine biological laboratory. Mill Bay and Sutton Pool are two small inlets of the Sound, in which lie all the merchant vessels bound for Plymouth proper. Between these inlets, and running along the shore, is the eminence or high plateau of land called the Hoe, embellished with interesting monuments. From this ridge, whence the approach of the Spanish Armada is said to have been first descried, magnificent shore and sea views may be obtained. Its eastern end is occupied by the citadel, which commands the entrance of the Cutwater (the lower estuary of the Plym) and of Sutton Pool. Mill Bay on the west is so deep that vessels of 3000 tons can lie at the pier at low water. The principal industries are ship-building and fisheries; the manufactures are unimportant, the chief being of chemicals, but as a naval station, the centre of the Devonshire and Cornwall trade, and as a holiday and health resort, Plymouth holds a prominent position. It carries on a considerable trade with the West Indies, South America, Australia, the Cape, the Baltic, and the Mediterranean. It has fine docks, harbors, and extensive quays, and a magnificent breakwater completed in 1841 protects the Sound with its spacious inner anchorage. The principal exports are lead, tin, copper, and granite; imports, agricultural products and timber. Plymouth was the first English town incorporated by Act of Parliament, its charter dating from November 12, 1439. It owns the oldest municipal water-works in England, originated in 1585 by Sir Francis Drake, the navigator, then Mayor of the town. It owns also profitable real estate, the Royal Hotel already mentioned, abattoirs, markets, a refuse destructor, the heat of which is utilized to generate electric light and power, electric tramways, suburban artisans' dwellings connected by tramways which carry workmen to any part of the town for a penny, baths, and wash-houses, and maintains free libraries, technical school, museum and art gallery,

the Hoe Park and pleasure grounds, a hospital ship, a borough hospital, and a lunatic asylum. The population of 'The Three Towns' in 1901 was 182,971, having tripled since 1821; that of Plymouth proper was 107,509.

Plymouth, described by Leland as being, in the reign of Henry II., "a mene thing, an inhabitation of fishars," was called by the Saxons Tameorworth (town on the Tamar); after the Conquest it was called Sutton (south town); and it was not till the reign of Henry VI. that it received the name of Plymouth (mouth of the Plym). During the fourteenth and fifteenth centuries it was frequently attacked, and set on fire by the French, and in 1512 an act was passed for the strengthening of its defenses, which since then have been greatly increased, until now the entire shore of the Sound is well defended by cannon, while a cordon of inland forts, constructed at immense cost, surrounds the Three Towns at a distance of from two to three miles. Plymouth witnessed the departure of Drake's noted expedition to circumnavigate the world in the reign of Elizabeth, and her fleet went forth from here to encounter the Spanish Armada. The *Mayflower*, when she sailed for America, landed at Plymouth, whence she finally set sail on September 6, 1620. During the Civil War the town successfully sustained a siege of four years for the Parliamentary cause, and was the first large town to proclaim William of Orange King. Consult: Worth, *History of Plymouth, from the Earliest Period to the Present Time* (Plymouth, 1871); Williams, *Plymouth* (ib., 1898).

PLYMOUTH. A town, port of entry, and the county-seat of Plymouth County, Mass., 37 miles southeast of Boston; extending for 18 miles along Plymouth Harbor, an arm of Massachusetts Bay, and along Cape Cod Bay, and on the New York, New Haven and Hartford Railroad (Map: Massachusetts, F 4). It is the oldest town in New England, having been the landing-place of the Pilgrims. Among the features of interest are the so-called Plymouth Rock, now covered by an open granite structure; Burial Hill and Cole's Hill, where many early settlers were buried; Pilgrim Hall, with its collection of paintings and relics; and the National Monument to the Pilgrims, dedicated in 1889. A statue of "Faith," 36 feet in height, is mounted on a granite base, 45 feet high, and is surrounded by massive tributary figures of 'Morality,' 'Law,' 'Freedom,' and 'Education.' Morton Park is the chief pleasure ground; and there is a public library with over 13,000 volumes. Plymouth is a well-known summer resort, and is of considerable industrial importance. The principal manufactures include cordage, tacks, rivets, woolen and knit goods, duck, stoves, foundry products, rubber goods, wire, etc. Plymouth Harbor is large but shallow, and there is little commerce other than coastwise trade. A number of vessels are employed in the fisheries. The government is administered by town meetings. There are municipal water-works. Population, in 1890, 7314; in 1900, 9592. Consult: Davis, *History of the Town of Plymouth* (Philadelphia, 1885); *Records of the Town of Plymouth* (Plymouth, 1889-92); and, especially for early history, Bradford, *History of Plymouth Plantation*, last ed. (Boston, 1898). See MASSACHUSETTS.

PLYMOUTH. A town and one of the county-seats of Grafton County, N. H., 51 miles north by west of Concord; on the Pemigewasset and Baker rivers, and on the Boston and Maine Railroad (Map: New Hampshire, II 7). Situated in a region noted for its scenic attractions, Plymouth is a popular summer resort. It is the seat of the State Normal School, and has the Holderness School for Boys and a public library. There are manufactures of shoe pegs, buckskin gloves, sporting goods, lumber, veneer goods, and butter. Nathaniel Hawthorne died here, and the old court-house is famous as the scene of Daniel Webster's first appearance as a lawyer. Population, in 1890, 1852; in 1900, 1972.

PLYMOUTH. A town and the county-seat of Washington County, N. C., 162 miles east of Raleigh; on the Roanoke River, near Albemarle Sound, and on the Atlantic Coast Line Railroad (Map: North Carolina, F 6). It has a State normal school (colored), and is the trade centre for a fertile section, the chief products of which are cotton, peanuts, tobacco, rice, farm produce, and lumber. Population, in 1890, 1212; in 1900, 1011.

PLYMOUTH. A borough in Luzerne County, Pa., four miles west of Wilkesbarre; on the Susquehanna River, and on the Delaware, Lackawanna and Western Railroad (Map: Pennsylvania, E 2). It is interested principally in coal-mining and in the coal trade, being situated among the rich anthracite fields of the State. There are also some manufactures, the chief products including mining drill machines, miners' squibs, hosiery, silk, etc. Plymouth was settled in 1768 by the Susquehanna Company, and until the close of the Pennamite-Yankee War in 1799 was claimed by both Connecticut and Pennsylvania. Population, in 1890, 9344; in 1900, 13,649. Consult Wright, *Historical Sketches of Plymouth, Pennsylvania* (Philadelphia, 1873).

PLYMOUTH BRETHREN. A religious sect which sprang into existence in the British Islands during the first half of the nineteenth century, and has extended itself throughout the British dominions and in certain parts of the Continent of Europe, particularly among the Protestants of France, Switzerland, and Italy, and in the United States of America. They do not use the name themselves, preferring to be called simply Believers, Christians, or Brethren. Their origin seems to have been due to a reaction against exclusive high-church principles in the Church of England and similar tendencies in other churches, and against a dead formalism associated with 'unevangelical' doctrine. While several communities appeared almost simultaneously in various places, the foundation of the body is generally ascribed to the labors and influence of John Nelson Darby, from whom on the Continent of Europe they are commonly known as Darbyites. Darby was born in London in 1800; he was graduated B.A. at Trinity College, Dublin, in 1819, and was called to the Irish bar in 1825. He withdrew from the Church of Ireland because of conscientious scruples regarding the scripturalness of church establishments; he also believed that denominational distinctions and a regular ministry should be discarded. He found others who shared his views, notably Anthony Norris Groves, a student at Trinity College, and an association was formed in Dublin in 1828.

Another was soon organized in Plymouth, and the fact that Providence Chapel in that town was the first regular place of meeting gave rise to the name Plymouth Brethren in 1830. Darby continued to labor as an evangelist, unconnected with any Church, in England and on the Continent, until his death in 1882. He preached in English, French, and German, wrote voluminously, and edited a quarterly periodical, *The Christian Witness*, which for a number of years was the official organ of the Brethren. His collected writings have been published in 32 volumes (London, 1867-83).

The doctrines of the Plymouth Brethren are Calvinistic. They emphasize original sin, predestination, the efficacy of Christ's sacrifice, the merit of His obedience, the power of His intercession, the gracious operations of the Holy Spirit in regeneration and sanctification. Millenarian views are also generally entertained. They practice the baptism of adults without regard to previous infant baptism. They hold meetings for Bible study and prayer, and observe the Lord's Supper weekly on Sunday. Their most distinctive peculiarity is their refusal to recognize any form of Church government or any office of the ministry; they insist on the equal right of every male member of the Church to prophesy or preach. They do not build churches, but meet in halls or private houses. A great schism took place among them during Darby's lifetime because of doctrines preached at Plymouth and Bristol concerning the human nature of Christ, and they have been frequently divided on narrow lines. There are four divisions in the United States (consult Carroll, *The Religious Forces in the United States*, New York, 1893). They number about 300 meetings in the United States and 100 in Canada. Consult the biographies of eminent members of the sect, as that of A. N. Groves (by his widow, London, 1856); Henry Craik (by Taylor, ib., 1866); the writings of B. W. Newton and W. Kelly; Guinness, *Who Are the Plymouth Brethren?* (Philadelphia, 1861); Dorman, *The Close of 28 Years of Association with J. N. Darby* (London, 1866); Henry Groves, *Darbyism, Its Rise and Development* (ib., 1866). For hostile criticism, consult Carson, *The Heresies of the Plymouth Brethren* (ib., 1862); Reid, *Plymouth Brethrenism Unveiled and Refuted* (Edinburgh, 1875); Croskery, *Plymouth Brethrenism, a Refutation of Its Principles and Doctrines* (London, 1879). Consult also Teulon, *The History and Teaching of the Plymouth Brethren* (ib., 1883); Neatley, *A History of the Plymouth Brethren* (ib., 1901).

PLYMOUTH CHURCH. The church in Brooklyn, N. Y., made famous by the long pastorate of Henry Ward Beecher, which lasted from 1847 until his death, forty years later. The original building was burned in 1849, when the present plain brick church was erected, seating 2800 people, and containing one of the largest organs in America.

PLYMOUTH COLONY. See MASSACHUSETTS.

PLYMOUTH ROCK. A ledge of rock in Plymouth harbor, Massachusetts, on which the Pilgrims are said to have stepped when disembarking in 1620. It is looked upon with veneration and celebrated in literature as a symbol of New

England principles. A beautiful granite canopy has been erected upon the rock.

PLYMOUTH ROCK. A breed of domestic fowls, popular and numerous throughout the United States, in several varieties. It is of large size, and has admirable qualities for market purposes. The favorite variety is the 'barred,' of a grayish-white color, every feather marked with many curving black bands. There are also clear white and clear buff varieties. The standard weight of the cock is 9.50 pounds; of hens, 7.50 pounds. See Colored Plate of FOWLS.

PLYMOUTH SOUND. A beautiful inlet of the English Channel between Cornwall and Devonshire, forming the harbor of Plymouth and Devonport, which is an important British naval station (Map: England, B 6). See PLYMOUTH, and the article BREAKWATER.

PLYMPTON, plimp'ton, GEORGE WASHINGTON (1827—). An American engineer and educator, born in Waltham, Mass. He graduated as a civil engineer from the Rensselaer Institute, Troy, N. Y. in 1847; was appointed professor of engineering and architecture in Cleveland University (1852), and the following year took the chair of mathematics in the New York State Normal School. He occupied a similar position in the State Normal School at Trenton, N. J., from 1857 till 1863, when he was made professor of physical science in the Brooklyn Polytechnic Institute, and six years afterwards took the same chair in the New York Cooper Union, of whose night schools he assumed direction in 1879. He was also professor of chemistry and toxicology at Long Island College Hospital, Brooklyn, from 1864 to 1886. His publications include *The Blowpipe* (1859), *The Starfinder* (1878), and *The Aneroid* (1880).

PLYNLIMMON, or **PLINLIMMON**. A mountain of Wales, on the boundary between the counties of Montgomery and Cardigan, 2481 feet in height. Although only 12 miles from the coast, it is in the midst of a wild waste of moor and bog, and on its slopes are the sources of the rivers Wye and Severn.

PNEUMATIC CLOCKS. See CLOCK.

PNEUMATIC DISPATCH (Lat. *pneumaticus*, from Gk. *πνευματικός*, *pneumatikos*, relating to wind or air, from *πνεύμα*, *pneuma*, air, wind, spirit). The name given to a method of sending mail matter, telegraphic dispatches, parcels, etc., through a tube by means of air pressure. The matter to be transported is placed in a carrier so designed as to fit closely the inside of the tube while being free to move, this carrier being propelled forward by introducing air under pressure behind it or by exhausting the air in front of it. Pneumatic dispatch was conceived as early as 1667 by Denis Papin, who, in a paper read before the Royal Society of London in that year, described a plan to exhaust the air from a tube in such a way that an interior piston would be propelled in the direction of the suction and haul a carrier attached to it by means of a chord. The first practical results with pneumatic dispatch, however, seem to have been obtained by Medhurst, an Englishman, who first described his system in a pamphlet published in 1810. Medhurst was followed by a score or more of inventors, some of whom achieved mechanical success, but it was not until 1853-54, when a

tube 220 yards long was built in London by the Electric and International Telegraph Co., to convey telegraph dispatches, that a practical working pneumatic system was put in actual operation for commercial purposes. This system was designed by Josiah L. Clark, and employed a tube 1½ inches in diameter, in which the carriers were dispatched in one direction only. This system was improved by C. F. Varley, who succeeded Mr. Clark as the engineer of the company named, and who increased the diameter of the tubes to 2¼ inches, and operated the carriers in both directions, using vacuum for sending in one direction and compression for sending in the other direction.

The next improvement in pneumatic dispatch was made by Siemens Bros., of Berlin, Germany, who proposed a circuit system in which two tubes were used, the 'up' tube being connected to the 'down' tube at the distant end; the air was compressed into one end of the circuit and exhausted at the other end, and furthermore it was kept in constant circulation, so that carriers were dispatched by inserting them into the tube without stopping the air current. To stop the carriers at intermediate stations, a wire screen could be inserted across the tube which would permit the air to pass, but would stop the carrier. The apparatus for sending and receiving carriers consisted of two short sections of tube attached to a rocking frame so that either could be swung by hand into line with the main tube. One of the tube sections was open at both ends and was used for dispatching carriers; a carrier was placed in it, then it was swung into line with the main tube, when the air current passing through swept the carrier along. The other tube section contained a perforated screen at one end and was used to receive carriers; when it was swung into line the air passed along through the screen, but the carrier was caught.

The first extensive application of the Siemens system was made in Berlin, Germany, in 1865, when a circuit was built between the telegraph station and the Exchange requiring 5670 feet of 2½ inch wrought-iron tube. This experimental line proved so successful that the system was rapidly extended until in 1897 there were 33 stations and 28 miles of tubes in use. In extending the system the Siemens system of operation was discarded; air was not kept constantly circulating, but power was stored up in large tanks, some being exhausted and others filled with compressed air. The exhausted tanks were permanently connected with the closed tubes, which were opened when required for use, and the tanks containing compressed air were connected to the tubes when messages were sent. The tubes were laid in circuits, including several stations in a circuit, and the carriers traveled only in one direction around the circuit. In 1866 the first stretch of pneumatic tube was laid in Paris and the system has been gradually extended since. As in Berlin, the tubes were laid in circuits, but instead of operating the circuit from a single power station each station of the circuit has a power plant and the sections of tubes between any two stations can be operated independently of the rest of the circuit. The carriers are run in trains, each train being propelled by a piston which pushes the rear carrier of the train, and these trains are dispatched every 15 minutes. Every train stops at all stations, where the carriers for that station are taken out and others

for succeeding stations are inserted. The speeds of the trains are from 15 to 23 miles per hour. Vienna, Austria, has a pneumatic dispatch system resembling that of Paris.

The London system of pneumatic dispatch differs from those of Continental cities just mentioned chiefly in being a radial system instead of a circuit system. The tubes radiate from a central power station to substations located at various points. In 1897 the system comprised 42 stations and 34 miles of tubes. The first London tube was installed by Siemens Bros., in 1870, but the present lines have been greatly improved over the original construction. Other British cities which have systems of pneumatic dispatch are Liverpool, Manchester, Birmingham, Glasgow, Dublin, and Newcastle. Mention should be made of the atmospheric railway built in London in 1863, from Euston to a station in Ever-shalt Street, 1800 feet, and extended in 1872 from Euston to the General Post-office, 14,204 feet. The original tunnel was a single tunnel flat on the bottom and D-shaped in section $2\frac{3}{4}$ feet high and $2\frac{1}{2}$ feet wide. The carriers were cradle-like boxes fitting the tunnel and they were moved at a speed of 17 miles per hour. The second line built was a double tunnel line each 4 feet high and $4\frac{1}{2}$ feet wide. These atmospheric railways were used to carry the mails for a time, but were found to be slow and expensive and were abandoned.

1893 the United States Post-office Department installed pneumatic dispatch between its main post-office and its substation at the Bourse, Philadelphia. This line is 2974 feet long, with tubes eight inches in diameter, and the carriers travel at a speed of about 25 miles per hour. This system has since been extended to reach the terminal stations of the Pennsylvania and the Philadelphia and Reading railways. In 1897-98 there were installed 6.83 miles of pneumatic dispatch connecting the general post-office in New York City with the Brooklyn post-office, the Grand Central Station, and intermediate substations. As the result of the experience with these lines, Congress, by an act dated June 2, 1900, ordered a committee of experts to be appointed to investigate and report upon the cost, construction, and utility of such systems for these and other large cities. This committee investigated these questions for eleven large cities and submitted a voluminous report in 1901.

The Batcheller system, which was first installed at New York and Philadelphia, on the lines in use in 1901, employed compressed air at a pressure of from five to ten pounds. The compressed air may be furnished by any improved type of air compressor or high-pressure blower and forces the carriage through a cast-iron pipe which is bored true and smooth and carefully jointed. The tubes, which are six and eight inches in diameter, are laid in a double line to facilitate

SENDING AND RECEIVING APPARATUS.

Perhaps the first attempt at pneumatic dispatch in America was made by A. E. Beach, who invented and exhibited a full-size working model of an atmospheric railway in 1867. Some years later Mr. Beach began the construction of an atmospheric railway tunnel under Broadway, New York City, and had completed a short distance of tunnel when the work was abandoned. In his working model Mr. Beach used a tube six feet in diameter through which a car seating ten persons was propelled by air pressure generated by a fan. This is the only attempt actually made in America at atmospheric railway construction. The use of pneumatic dispatch has, however, become quite extended. Perhaps the most extensive use of small pneumatic tubes in stores for dispatching cash to and from a centrally located cashier's desk. Seamless brass tubing is generally used and the power is supplied by rotary blowers. The Western Union Telegraph Company has pneumatic dispatch systems in use in New York and Chicago, and similar private systems are in use elsewhere. In

traffic in opposite directions. The carriers are symmetrical in form, of the shape shown in the illustration, and of a diameter about one inch less than that of the tube. A door in the end of each carrier gives access to the interior. They are from 16 to 30 inches in length and weigh from 7 to 16 pounds. Near each end are placed packing rings of cotton fabric secured to the

SECTION OF CARRIER.

main body by metal collars so as to insure a close fit in the tube. These packing rings are lubricated by vaseline, which makes easy running possible. The sending and receiving apparatus, which is located at each end and also at intermediate stations on the line, is shown in the il-

Illustration. In the sending apparatus two sections of the tube are supported in a swinging frame so that either can be brought into line with the main tube, through which there is a constant current of air. After a carrier has been placed in an iron trough it passes into an open tube section and is then swung into position so that it is in line with the main tube and the carrier is swept along by the pressure. The car-

riers usually have a headway of from five to fifteen seconds each, and may be dispatched automatically. There are various forms of receivers, the use of which depends upon various conditions of atmospheric pressure. The action of the receiving apparatus is automatic, and as soon as a carrier arrives in the receiving chamber the latter is tilted and the carrier is discharged and the receiving chamber returned to its normal horizontal position. Automatic apparatus is also employed at the intermediate stations and the carriers designed for a particular station are turned aside from the main line tube. The use of pneumatic apparatus is constantly increasing and there are cities in the United States in which it is being installed for the transmission of small packages.

to discharge a quantity of high explosive. The most successful pneumatic gun, the invention of Capt. E. L. Zalinski, U.S.A., is designed to discharge projectiles loaded with a high explosive, such as dynamite, the shock of the discharge being kept low by the use of air. Pneumatic guns have not been taken up by governments, because it is felt that the problem of projecting a mass containing high explosives is not thoroughly solved by such means. See AIR GUN; ORDNANCE.

PNEUMATICS. The branch of mechanics which treats of the properties of gases, either at rest or flowing, and of solids immersed in gases. See GASES, GENERAL PROPERTIES OF.

PNEUMATIC TOOLS. The name given to a class of portable, self-contained motor tools (generally hand tools), for metal and wood working, operated by compressed air. Pneumatic tools are of two types, viz. percussive tools and rotary tools. In the first type work is done by rapidly repeated percussive blows and in the second type by a rotary or boring action. The motive power used in both is air under pressure, and the motor is contained within the tool. The variety of purposes to which pneumatic tools are put is very great; a recent authority has stated that there are between 70 and 80 different styles of such tools in use and that new appliances are being constantly discovered. Some of the general mechanical operations to which such tools are applied are hammering, ramming, calking, chipping, riveting, shaving, drilling, boring, screwing, clipping, carving, and expanding tubes. As will be seen, these operations are nearly all of the sort which permit the primary mechanical actions of the tool—percussion and rotation—to be employed without modification. It will be sufficient for a general understanding of pneumatic tools, therefore, to describe briefly typical percussive and typical rotary tools.

PERCUSSION TOOLS. The mechanism employed for utilizing compressed air to secure percussive

SENDING APPARATUS. -

SECTION OF KELLER PNEUMATIC HAMMER ARRANGED FOR RIVETING, SHOWING OPERATING PARTS.

BIBLIOGRAPHY. For a comprehensive description of the Batcheller pneumatic dispatch system, particularly as installed at Philadelphia, Pa., see Batcheller, *The Pneumatic Dispatch Tube System* (Philadelphia, 1897). The results and conclusions of the committee appointed to investigate the subject of pneumatic dispatch for the Post-office Department have been published by the Postmaster-General under the title of *Pneumatic Tube Service* (Washington, D. C., 1900).

PNEUMATIC GUN. A gun in which the expansive force of air under pressure is employed

action is essentially the same in all pneumatic tools of this type, and it will be sufficient to describe the mechanism in one of them only, and for this purpose the hammer will perhaps serve best. The pneumatic hammer consists essentially of a cylinder containing a piston which, by means of suitable cylinder inlet and exhaust openings for air under pressure, is made to reciprocate back and forth in the cylinder. A tool is inserted into the front end of the cylinder loosely in such a way that the reciprocating piston or hammer strikes its near end at each forward stroke, the

action being exactly analogous to that of a man driving a chisel with a hand hammer. The rear end of the cylinder terminates in a handle by which the tool is held by the operator. Compressed air is conveyed to the cylinder by means of a suitable connection or a flexible hose. The variety of constructions by which the piston stroke is actuated and controlled is large, but generally speaking all pneumatic hammers may be classed either as valveless hammers or valve hammers, one of the former class, the Keller tool, being shown in the diagram and in various application on the accompanying plate. The valveless hammers have no valve beyond the striking piston, this being itself a valve to effect the proper admission of air to alternate ends of the working cylinder. In the valve hammers a reciprocating valve, working either at right angles to or parallel with the striking piston, acts in combination with it to regulate the inlet and the exhaust of the compressed air.

There are several constructions of both valveless and valve hammers, each of which is controlled by patents owned by the manufacturers of such tools. The general characteristics and comparative merits of the two forms of construction may be summarized as follows: Valveless hammers have essentially a short stroke, and although economical in air consumption in relation to the number of blows given, they do not compare with valve hammers in giving powerful blows, which are necessary in heavy chipping and riveting. Owing, however, to their simple construction, they have probably a longer life than valve hammers, and for such purposes as beading flues, light calking and chipping, and especially carving in stone, they compare very favorably with their rivals. The speed of the valveless hammers is very high, being from 10,000 to 20,000 strokes per minute. The speed of valve hammers for ordinary work ranges from 1,500 to 2,000 blows per minute, although they can be driven much faster. Their stroke is considerably longer than that of valveless hammers, and the blow struck is correspondingly greater. These characteristics of valve hammers make them most suitable for general and heavy clipping, calking, and riveting. This comparison is a fair summary of recent engineering opinion on the subject, but advocates of one or the other form naturally contest the claims of its opponents. The preceding description has referred particularly to hammers; by replacing the hammer tool struck by the piston as above described with sharpened or otherwise specially formed tools we have the hammer converted into a tool for chiseling, chipping, beading, calking, riveting, etc. In operation the apparatus is held by the handle so that the tool presses firmly against the work; air pressure is then turned on by pressing a trigger or thumb lever on the handle and the reciprocating piston begins to strike the tool, which is thus caused to cut or hammer the work in front of its nose. As previously stated, the blows are exceedingly rapid, their sound coming to the ear as a continuous buzz, and they depend for their effect upon their great frequency rather than upon their individual energy. Pneumatic percussion tools are made in a variety of sizes, but with the exception of riveters their weight and dimensions are kept small enough to permit them to be manipulated by hand. As specially designed for rivet-

ing work the percussive pneumatic tool requires brief special description. Any of the regular hammer tools may be used for riveting in connection with a holder-up for supporting the butt of the rivet, but such work is more effectively accomplished by heavier tools having a longer stroke. The yoke riveter is another common form and consists of a U-shaped yoke having at the end of one arm an inwardly projecting holder-up. The yoke riveter is made in several modifications designed for special purposes and requires generally to be handled by chain or pneumatic hoists or other power. (For illustration, see METAL-WORKING MACHINERY.) In clipping tools the stroke of the piston is reduced enormously in speed and it is provided with a piston rod which acts on a suitable hinged link construction to convert its rectilinear motion into a pincer-like movement of the clipping edges or jaws. In the forms of percussion pneumatic tools described the intensity of air pressure used is from 80 lbs. to 100 lbs. per square inch for all work except riveting, where it is usually increased up to 125 lbs. per square inch.

ROTARY TOOLS. Rotary pneumatic tools, commonly called portable pneumatic drills, are used for drilling and boring wood and the analogous operations of reaming, tapping, tube-expanding,

KELLER PNEUMATIC DRILL OPERATED BY ROTARY MOTOR.

screwing nuts on bolts, boring cylinders and Corliss engine valve seats; also for turning crank pins, grinding steam-pipe joints, and cleaning castings. The method by which compressed air is utilized for driving the drills is generally by means of single or double acting cylinder motors, the cylinders of which are sometimes fixed and sometimes oscillating, which actuate suitable mechanism for turning the bit and are inclosed in the body of the drill. Rotary motors are also used, and an example of one of these, the Keller tool, is shown diagrammatically in the illustra-

5. CALKING A BOILER.

tion and in actual use on the accompanying plate. Pneumatic drills are made in a large number of sizes from light drills suitable for small holes up to machines of two or three horse-power. They work with from 60 pounds to 80 pounds air pressure. For performing different kinds of work, assuming the size to be ample, the only change necessary is the substitution of the proper tool (drill, auger, saw-bit, reamer, etc.) in the tool-holder. A description of the motor construction of several well-known tools will give a fair idea of this mechanism. In the Little Giant drill the motor consists of four single-acting cylinders arranged in pairs and coupled to opposite ends of a crank shaft. The crank shaft carries pinions which gear with spur wheels on the tool shaft. The entire mechanism is inclosed in a shell shaped like the section of a circular cylinder. The Whitelaw drill has two double-acting oscillating cylinders geared to a crank shaft which carries a single pinion gearing with a spur wheel on the tool shaft. In the Boyer piston drill the motor is in the form of a three-cylinder single-acting oscillating engine, the cylinders being carried in a rotary frame, which, since the cylinder pistons are coupled to a fixed crank, rotates and by means of suitable gears causes the tool shaft to rotate. The motor mechanism is all inclosed in a cylindrical casing. Air is piped to these rotary tools by flexible hose exactly as in the case of percussion tools.

The use of pneumatic tools has been most highly developed in the United States, but it is extending rapidly in European countries. Their particular field of usefulness is in performing work formerly performed by hand, because of the inability of transporting the ordinary heavy shop tools to the work. For example, in riveting the connections of metal bridges during erection in the field the work has to be done on stagings and scaffoldings high in the air. These positions are inaccessible to heavy shop riveting machines, and until the advent of the pneumatic tool such work was of necessity performed by hand; the portable pneumatic riveter can be used in almost any place where hand riveting is possible with a gain in all things in which machine work surpasses hand work.

PNEUMOGASTRIC (nū'mō-gās'trik)
NERVE (from Gk. πνεύμων, *pneumōn*, lung + γαστήρ, *gastēr*, stomach), or PAR VAGUM. A nerve which derives the first of its names from its supplying the lungs and stomach with nervous filaments, and the second from the wandering course which it pursues. It emerges from the medulla oblongata by eight or ten filaments, which unite and form a flat cord that escapes from the cavity of the cranium (in association with the glossopharyngeal and spinal accessory nerves) by the jugular foramen. In this foramen it forms a well-marked ganglionic swelling, while another is observed immediately after its exit from the skull. The nerve runs straight down the neck between and in the same sheath as the internal jugular vein and the carotid artery. Below the root of the neck its course is different on the two sides; the right nerve, running along the back of the œsophagus, is distributed to the posterior surface of the stomach, and finally merges into the solar plexus, while the left nerve runs along the front of the œsophagus to the stomach, sending branches chiefly over its anterior surface.

From anatomical considerations, based on the

distribution of this nerve, and from the results of experiments on animals, it may be concluded that this is a mixed nerve, containing filaments both of sensation and motion. The pulmonary branches exercise a most important influence upon the respiratory acts, for when the pneumogastrics on both sides have been divided above the giving off of the pulmonary branches, the most severe dyspnoea comes on, the number of respirations is much diminished, and the animal breathes as if it were asthmatic; after a short time the lungs become congested and finally consolidated, while the bronchial tubes are filled with a frothy serous fluid; and if the cut ends of the nerves are kept apart, the animal never survives above three days. The gastric branches influence the movements of the stomach, while their destruction does not materially affect the secretion of the gastric juice of further digestive reactions. Loss of voice and difficulty of breathing have been frequently traced to the pressure of an aneurism or other tumor on the recurrent or inferior laryngeal. The sympathy which exists between the digestive and the respiratory and circulating organs is explained by the anatomical relations of this nerve. For example, both asthma and palpitation of the heart are often to be traced to some deranged state of digestion. Vomiting may be excited by irritation of the central or the distal extremities of the nerve. In disease of the brain the vomiting, which is often an early symptom, is caused by irritation of the central extremity; while, on the other hand, by introducing emetic substances into the stomach the vomiting is produced by the irritation of the peripheral (or distal) filaments.

PNEUMONIA, nū-mō'nī-ā (Neo-Lat., from Gk. πνευμονία, disease of the lungs, from πνεύμων, *pneumōn*, lung, from πνέω, *pnéō*, to breathe). An inflammation of the substance of the lung. There are three well-defined forms: Acute lobar pneumonia, broncho-pneumonia, and chronic interstitial pneumonia.

Acute pneumonia is called *lobar* because it involves usually an entire lobe or successive lobes of the lung; *croupous* from the character of the exudation into the air cells or alveoli. The disease is due to a specific germ, the *Pneumococcus* or *Diplococcus pneumoniae*, although streptococci and staphylococci are always found with it. It is infectious and in a measure contagious, and sometimes occurs epidemically in institutions and houses. It is apt to attack persons in a depressed physical or mental condition; it is more prevalent in the spring and autumn than at other times, and is a disease of adults up to middle age. Unlike most specific fevers, one attack does not confer immunity, but rather predisposes to others. Pneumonia begins with a chill, high fever, and a severe pain in the side, attributable to the accompanying pleurisy. As the malady progresses, there is a cough, with a viscid, airless, rusty sputum, later becoming yellow. Respirations are rapid and shallow, 40 or 50 to the minute; the pulse is also rapid, the cheeks flushed, and the general prostration extreme. There are in addition headache, sleeplessness, and sometimes delirium. These symptoms continue with more or less severity until the crisis occurs, from the fifth to the eleventh day, when the temperature falls quite suddenly, almost to normal, and rapid improvement sets in. In a few cases a crisis does not occur, but the temperature declines gradu-

ally. Death takes place in fatal cases from heart failure, due to toxemia. During the progress of pneumonia, the affected portion of the lung goes through three stages. In the first or stage of hyperæmia, the lung is congested, has a reddish brown color, and there is a slight exudation into the air cells. It is heavier than normal and contains less air. This stage lasts from one to three days, and is followed by the stage of exudation or red hepatization. In this the lung is red (resembling, when cut into, a section of liver), sinks in water, and the air sacs are completely filled with viscid, fibrinous fluid mixed with blood corpuscles. In from three to seven days the stage of resolution or gray hepatization sets in. The exudate filling the alveoli now undergoes liquefaction and is partly absorbed and partly expelled by acts of expectoration. This stage may endure from one to three weeks. Sometimes resolution is delayed, the exuded material undergoes purulent transformation, and single or multiple abscesses of the lung result. Pneumonia is a self-limited disease, and treatment is therefore not directed toward cutting short an attack, but toward keeping up the patient's strength, supporting the heart, and reducing the temperature. It is particularly in the second stage that the patient is in danger, when the fever is at its height and the heart embarrassed. Alcohol, strychnine, and straphanthus are the most useful cardiac stimulants, and cold sponging and cold packs or baths the usual methods of reducing the fever. During the third stage expectorants are exhibited to assist in bringing up the exudate, and during convalescence tonics are given to build up the strength and restore the wasted tissues.

Broncho-pneumonia (catarrhal or lobular pneumonia) attacks principally young children and old people by an extension downward of a bronchitis. It often occurs as a complication of the eruptive fevers, especially measles, and of whooping-cough. The disease affects the mucous membrane lining the finer bronchial tubes (whence it has been called capillary bronchitis) and the air cells. These become blocked up by a yellowish mucoid material and larger or smaller portions of the lung are deprived of air. The symptoms of this variety of pneumonia are similar to those of the croupous form, except that the temperature rises more gradually and the rapidity of respiration is out of all proportion to the amount of tissue involved. The disease may be acute, subacute, or chronic in its course, and nearly one-half of the cases die. The treatment is designed, as in croupous pneumonia, to keep up the strength, and assist in the expectoration of the toxic material. A steam kettle is kept going in the sick-room, poultices are applied to the chest, and expectorants and a nourishing liquid diet are given throughout the attack.

Chronic interstitial pneumonia (cirrhosis of the lung) is a comparatively rare disease, found in miners, stone-cutters, grinders, and others whose occupation necessitates the inhalation of irritating particles. It sometimes follows acute pneumonia in which resolution has been delayed, and generally terminates as a tuberculous process. There is an overgrowth of the fibrous framework of the lung at the expense of the respiratory elements. The organ shrinks sometimes to half its normal size, and is heavy and tough in consistence. There is always an associated chronic bronchitis, with cough and ex-

pectoration. The course of the disease is slow, extending over ten or fifteen years. The treatment of this disease consists in placing the patient under the best possible hygienic and climatic conditions—a warm climate in the winter and a bracing one in the summer, with the administration of tonics, such as cod-liver oil, iron, and quinine.

Among animals the horse perhaps most frequently exhibits symptoms characteristic of pneumonia. Bad ventilation, improper attention to the needs of the animal, etc., are frequent causes. Remedies are similar to those used for the human subject.

PNOM-PENH (*Fr. pron. pnôn'pên'*). The capital of the French protectorate of Cambodia, 130 miles northwest of Saigon, on the Mekong River (Map: French Indo-China, E 5). The most noteworthy features are the palace of the Buddhist priests, the Government buildings, and the pagoda. The shelling of cotton seeds is an important industry, and the town is also a prominent trade centre. Population, about 50,000.

PNYX, níks (Lat., from Gk. πνύξ). A hill and ancient place of assembly, whose exact location is not known, in Athens.

PO (anciently *Padus* and *Eridanus*). The largest river of Italy, flowing through Piedmont and Lombardy, and along the southern borders of Venetia. It rises on Monte Viso, in the Cottian Alps, and flows in a general easterly direction through the great valley between the Alps and the Apennines, emptying into the Adriatic Sea after a course of 390 miles (Map: Italy, F 3). It falls very rapidly in its extreme upper course, its ultimate sources being at a height of 6000 feet. In the lower half of its course, however, it is a comparatively sluggish stream, flowing over a raised alluvial bed so that its surface is higher than the surrounding country, and its banks have to be protected by dikes, which extend continuously from Cremona to the delta. These levees, however, do not follow the smaller windings of the river, but cut across peninsulas, which, though unprotected, are cultivated, but are submerged at every considerable rise of the river. The volume of water discharged by the river is nearly equal to that of the Rhine. The greater part is received from the Alps, and nearly one-half comes from the series of large lakes on the southern slope of the mountains. The principal tributaries from the left are the Dora Riparia, Dora Baltea, Sesia, the Ticino, the outlet of Lago Maggiore, the Adda from Lago di Como, the Oglio from Lago d'Isèo, and the Mincio from Lago di Garda; from the right the Po receives the Tanaro, Trebbia, Taro, and Panaro. Since the Po is fed exclusively by mountain torrents, the quantity of sediment carried by its current is enormous, the absolute quantity being nearly equal to that carried by the Mississippi. As a result of this the delta of the Po grows with nearly the same rapidity as that of the great American river; it advances into the Adriatic at the rate of more than 200 feet per year. The delta and the surrounding country consist of unhealthy marshes, and there are scarcely any towns on the lower course of the river. The chief cities on its banks are (ascending) Cremona, Piacenza, Casale Monferrato (the head of navigation, 337 miles from the mouth), and Turin. The plain of the Po is of great fertility.

POA, pō'á. See MEADOW GRASS.

POACHING (OF. *pocher*, from *poche*, pocket, probably from Ir. *poc*, Gael. *poca*, pocket, or less probably connected with OF. *pocher*, *poucher*, to thrust, hit, and ultimately with Eng. *pochard*, which see for etymology). In English criminal law, the act of unlawfully trespassing on another's lands for the purpose of killing or taking game, or for the purpose of catching fish. It embraces a variety of statutory offenses, with respect to game and fish, by persons having no sporting rights. These statutes were enacted in the interests of the public, primarily for the purpose of protecting game and fish which are valuable for food. Such animals are not treated by English law as the subjects of larceny, and, but for special legislation, persons taking them from another's lands would be liable only to a civil action for trespass. English game and poaching statutes make such taking a crime. The existing legislation on this topic begins with the Night Poaching Act, 1828 (Geo. IV., c. 69), and the Day Poaching Act of 1831 (1 and 2 Geo. IV., c. 32). These were called forth by the rapid increase of poaching which followed the close of the Napoleonic wars. Such increase has been ascribed to the distress prevailing in agricultural districts during the third decade of the last century, and to the large number of turbulent spirits thrown out of military employment and cast back into the ranks of ordinary laborers. The acts referred to above made poaching a crime instead of treating it, in its various forms, as an offense which could be condoned by a money penalty. They also legalized the sale of game which had been lawfully captured or killed.

POACHING GAME. By the Night Poaching Act, it is provided that any person unlawfully trespassing in search of game by night—i.e. between the first hour after sunset and the first hour before sunrise—shall for a first offense be committed by the justices to the house of correction for three months, or in some cases for six months; for a second offense shall be committed for six months, or in some cases for twelve months; and for a third offense shall be guilty of a misdemeanor and be imprisoned for two years. In case such night poachers are found on the lands and in the act, the owner or occupier of the land or his servants may arrest the poachers and take them before justices. If the night poacher, when arrested, use firearms, sticks, or offensive weapons, he shall be guilty of a misdemeanor and be punishable by two years' imprisonment in addition. In case of three or more night poachers being armed with guns, bludgeons, or other offensive weapons, each is guilty of a misdemeanor, and is liable to imprisonment for three years. Poachers have no right to kill game on the highway any more than in fields or inclosures, for the owners of the adjoining land are entitled to the game on the highway.

By the Day Poaching Act, whoever unlawfully goes upon lands not his own to pursue or kill game of any kind is liable to a penalty of £2. When a poacher is found trespassing on lands in search of game, the person entitled to the game there, or the tenant, or a gamekeeper, or servant of either, may demand the poacher's name and place of abode, and if it is refused, may arrest such poacher, and take him before a justice of the peace; but the poacher must be taken within twelve hours before the justice, otherwise he is

entitled to go at large. It is only the persons named (and not any one of the public, or even a constable) who can arrest the poacher, and it can only be done when he is caught in the act on the very lands; for if the poacher clear the fence, and go on to other lands, he cannot then be arrested at all. If the poacher when convicted does not pay the penalty within the time fixed by the justices, he may be committed to the house of correction for a period not exceeding two calendar months. The party may appeal against his conviction to the Court of Quarter Sessions; but he must either remain in custody in the interval or give security for the costs.

By the Poaching Prevention Act, 1862 (25 and 26 Vict., c. 114), which applies to the United Kingdom, if a constable now meet a suspected poacher on the highway, whom he has reason to suspect of coming from land where he has been poaching, such constable may stop and search the poacher; and if game, or implements for taking game, are found on him, may seize and detain them, and summon him before the justices. When before the justices, if it be proved by circumstantial evidence or otherwise that such game was procured by poaching, or that the implements were used, the poacher may be fined in a penalty of £5, besides forfeiture of the game, and guns, nets, and other implements which he may have so used. The person convicted may appeal if he chooses to the next Quarter Sessions, or in certain cases to the Court of King's Bench. With regard to the poacher's property in the game he kills, it is only in those cases where he is caught in the act and on the spot that the game can be taken from him; and this, for obvious reasons, seldom happens. In all other cases the general rule applies that whoever first catches (whether legally or illegally) a wild animal is entitled to the property in it; and as game is in the category of wild animals, the poacher is entitled to keep the game, except where it was both started and caught on one and the same person's lands.

POACHING FISH. The law of fisheries is not uniform in the United Kingdom. In England the general rule is that any one of the public may fish freely in the sea and in all navigable rivers; and where he can fish he can catch salmon as well as every other kind of fish. But there is an exception to this general rule, which consists in this, that as the Crown could before Magna Charta (which took away such right) legally grant a several or exclusive fishery in the sea or navigable river to an individual, and as this was, in point of fact, often granted, it follows that it is not uncommon to find, even at the present day, an individual, generally the lord of an adjacent manor, still claiming a several fishery in these places. If he can prove that he has exercised this exclusive right as far back as one or two centuries, it will be inferred that his right dates from before Magna Charta, and therefore will be legal. When such is the case the public have no right to fish even in a navigable river or the sea at the specified places, the sole fishery being vested in this individual owner. In streams not navigable the rule is that each riparian owner—i.e. the owner of the lands on the bank of the stream—has a right to a several or exclusive fishery up to the middle line of the stream. If he is owner on both sides of the stream, then he has the exclusive fishery in the whole of the stream, so far as his lands extend. As to ponds, whoever is owner of

the soil is the owner of a several fishery there, unless he has let it to another. As to lakes, it is not clearly ascertained how the fishery is to be divided between the owners of the lands abutting thereon, but much will depend on the title to the lands and the subsequent user. As a general rule, there is no such thing as a right in the public to fish anywhere except in a tidal river or the sea, and that is subject to the exception of an individual claiming a several fishery, as before mentioned. It is often supposed that, at all events, if a highway adjoins a private stream, any one may fish in the stream or angle there; but this is a delusion. Nobody is entitled to use a highway for the collateral purpose of either fishing or poaching, the use of the highway, so far as the public are concerned, being confined to the purposes of traveling or transport.

The general rule as to all several—i.e. exclusive—fisheries is that whoever goes and poaches the fish commits an offense, for which he may be summoned before justices and fined £5 over and above the value of the fish taken; and if the fishery where he poaches is adjoining the dwelling house of the owner of the fishery it is a still higher offense, for it is then an indictable misdemeanor. Whenever a fish-poacher is caught in the act of poaching, he may be at once apprehended, not only by the owner of the fishery, but by anybody; but this can only be done while he is on the spot or near it, for if he escape to the highway or to other lands before being arrested, he cannot then be apprehended, but can only be summoned before justices in the usual way. In this respect a privilege is given to anglers, for in no case can these be arrested if angling during the daytime; they can only be summoned for the offense. Though anybody may arrest the fish-poacher, still it does not follow that the fish poached can be taken from the poacher; on the contrary, the rule is the same as with reference to game, that whoever first catches the fish, whether legally or illegally, is entitled to keep it; and though game can on certain occasions be taken from the poacher, this is by reason of an express provision in the Game Act; but there is no similar provision as to poached fish, so that the poacher, whatever other punishment he may incur, does not lose his fish. With regard, however, to the poaching implements, such as nets, it is provided by an express section of the Larceny Act, 1861 (24 and 25 Vict., c. 96, s. 25), that the owner of the fishery or land where the poacher is caught, or his servant, may demand, and if refused, may seize, the net, rod, line, hook, or other implement used for taking the fish, but no other person can seize these.

The laws of Scotland as to poachers of fish differ in some respects from those of England. In Scotland salmon belongs *prima facie* to the Crown, not merely in rivers, but on the seacoast. Hence, the public have no right to fish with nets even in the sea, except by leave of the Crown, or of the grantee of the Crown at the spot in question. Where a salmon-river belongs to several proprietors, the rule is that none can fish by using fixed engines; but the only legal mode is the mode of fishing by net and coble (or boat). Whoever poaches salmon in a river, lake, or within a mile of the seashore incurs a penalty of £5, besides forfeiting the boat, net, or other engine used to catch the fish. While the law is as above stated with respect to fishing salmon with

nets, a grant from the Crown is required to enable even a riparian owner to angle for salmon. As regards other fish than salmon, the general rule is that the riparian owner is entitled to catch all the fish he can, provided he do not interfere with the superior right of some Crown grantee of the salmon-fishery. A person who poaches trout or other fresh-water fish with a net, or by double rod-fishing, or cross-line fishing, or set-lines, etc., incurs a penalty of £5, besides forfeiture of the fish caught. And he may be arrested if he is net-fishing, but not if he is fishing in another way. Moreover, a mere angler of trout, though a poacher, cannot be arrested, nor yet punished by any penalty, though he is liable to an action at law, which, however, is virtually no remedy at all. So, in the case of all poachers of trout (except angling poachers, who can neither be arrested, nor yet have their fish or fishing-rod taken from them by force), the owner of the fishery, or any person authorized by him, may seize the nets, boats, and fishing implements if the poachers are found on the spot. In Ireland the law applicable to poachers of fish is the same as in England. Consult: Woody, *Game Laws of England* (London, 1896); Paterson, *Treatise on the Fishing Laws of the United Kingdom* (ib., 1878); Oke, *The Whole Law as to Game Licenses and Poaching* (ib., 1897); "Poaching," *173 Quarterly Review* (ib., 1891); Stephen, *History of the Criminal Law of England* (ib., 1883).

POCAHONTAS (c.1595-1617). A celebrated Indian 'Princess,' daughter of Powhatan (q.v.). She is first mentioned in the *True Relation* (1608) of Capt. John Smith (q.v.) as "a child of tenne yeares old, which not only for feature, countenance, and proportion much exceedeth any of the rest of his [Powhatan's] people, but for wit and spirits the non-pareil of his country." She seems to have formed an attachment for the whites—especially for Smith—and to have been a frequent visitor at Jamestown until Smith left in October, 1609, when her visits ceased. In April, 1612, while at the village of her uncle, the 'King of Potowomek,' she was lured aboard an English vessel by Captain Argall, and was taken to Jamestown as a hostage for the return of several white prisoners and some stolen property. Here she was converted to Christianity and in April, 1613, was baptized and christened Rebecca. In April, 1614, she was married to John Rolfe (q.v.), with whom, two years later, she went to England, where she was received with great enthusiasm, as the daughter of an American 'King.' Then it was that the celebrated story about her rescue of Captain Smith first appeared. In a letter to the Queen (1616) Smith asserted that in 1607, when he, a captive among the Indians, was about to have his brains knocked out against a large stone, Pocahontas had "hazarded the beating out of her owne braines" to save his, and had on another occasion warned the English of a threatened Indian attack, besides furnishing food to the famishing colonists. It is for this rescue story, much elaborated and embellished by Smith in his *Generall Historie* (1624), that Pocahontas is chiefly remembered. Until Charles Deane attacked it in 1859, it was seldom questioned, but, owing largely to his criticisms, it soon became generally discredited. In recent years, however, there has been a tendency to retain it. Pocahontas died March 29, 1617, at Gravesend, and was there buried, the following

curious entry being made in the parish records: "1616 (1617), May 2 j, Rebecca Wrothe wyff of Thomas Wrothe, gent. a Virginia lady borne, here was buried in ye chauncell." Pocahontas and Rolfe had one son, Thomas, who, after living for many years in England, migrated to Virginia. From him many prominent Virginia families, including the Bollings, the Murrays, the Guys, the Whittles, the Robertsons, the Elbridges, and that branch of the Randolphs from which sprang John Randolph of Roanoke (q.v.), trace their descent. For arguments opposing the rescue story, consult Deane's edition of Smith's *True Relation* (1866), Neil's *Virginia Company in London* (1869), and Henry Adams's *Chapters of Erie and Other Essays* (New York, 1871); for arguments in its favor see: Arber, *Smith's Works* (1884); Poindexter, *Capt. John Smith and His Critics* (1893); W. W. Henry, *Proceedings of the Virginia Historical Society* (1882); and John Fiske, *Old Virginia and Her Neighbors* (1897). Consult, also: Eggleston and Seelye, *Pocahontas* (New York, 1879); and Robertson and Brock, *Pocahontas and Her Descendants* (1887).

POCATELLO. A city and the county-seat of Bannock County, Idaho, 134 miles north by west of Ogden, Utah; on the Port. Neuf River, and on the Utah Northern and the Oregon Short Line railroads (Map: Idaho, C 4). It is a division headquarters of these lines and has large railroad machine shops. The soil of the surrounding region is of volcanic origin, and has been made very productive by means of irrigation. Mining, stock-raising, and agriculture constitute the leading industries. The Academy of Idaho is located here. Pocatello is the second largest city in the State, having, in 1900, a population of 4046.

POCETTI, pò-chét'tè, BERNARDINO BARBATELLI (1542 or 1549-1612). An Italian painter, born at Florence, where he was a pupil of Michele di Ridolfo del Ghirlandajo. He enjoyed great reputation as a painter of grotesques, whence he was also named "Bernardino dalle grottesche," and after his return from Rome, where he had assiduously studied the works of Raphael and other great masters, executed a great number of mural paintings in Florence and throughout Tuscany, revealing himself as a graceful figure painter, who enriched his historical compositions with beautiful landscapes, sea views, fruits and flowers, besides magnificent draperies and tapestries, which he imitated to perfection. In Florence some of his frescoes may still be seen in Santissima Annunziata, in Santa Maria Novella, in the Monastery of San Marco, in the Certosa, in the Uffizi, and in the Pitti Palace. His finest ceiling pieces are reproduced in *Deckenmalereien des ersten Korridors der Uffizien zu Florenz* (Berlin, 1897).

POCCI, pò'chè, FRANZ, Count (1807-76). A German poet, artist, and musician, born at Munich and educated in law at Landshut and his native city. His first publications to attract attention were *Bildertöne für das Klavier* (1835) and *Sechs altdeutsche Männelieder* (1835), and he afterwards wrote many popular hunting and student songs. His further publications include *Dichtungen* (1843), *Dramatische Spiele* (1883), and *Gevatter Tod* (1855). He is, however, chiefly remembered by his literary-artistic productions for children, such as *Rosengärtlein* and *Lustiges Bilderbuch*.

POCHARD (also *poker*, formerly *poachard*, *poard*, from *poach*, from OF. *pocher*, *pucher*, Fr. *pocher*, to thrust, hit, from L.Ger. Dutch *poken*, to thrust, from Gael. *puc*, Ir., Corn. *poe*, push; OF. *pocher*, *poucher*, is also explained as from *pouce*, *poutec*, thumb, from Lat. *pollex*, thumb, from *pollere*, to be strong). An Old World sea-duck (*Aythya farina*), with a long, broad, and very flat bill, the wings short, and the tail short and rounded. It is smaller than the mallard, but rather larger than the widgeon. The head and neck are bright chestnut, the eyes red. The wind-pipe of the male, in all the pochards, terminates in a labyrinth composed partly of bone and partly of membrane. It breeds in far northern regions, and in winter migrates southward, even as far as Bengal. It is highly esteemed for the table. The canvasback and the redhead (qq.v.) of the United States are closely allied species. The pochard is also known as 'dun-bird' and 'poker.' See DUCK.

POCKET GOPHER, or POUCHIED GOPHER. Any gopher (q.v.) of the family Geomyidæ,

POCKET GOPHER.

1, The face, showing openings on each side of the cheek-pouches; 2, left fore foot, showing great digging claws.

characterized by their large cheek pouches, which are furry inside and open outside of the mouth. The 'salamander' of the Southern States and the

SKULL OF POCKET GOPHER.

common gopher of the Western prairies are examples. Consult *North American Fauna*, No. 8 (Department of Agriculture, Washington, 1898).

POCKET MOUSE. A mouse of the American family Heteromyidæ. They have external cheek-pouches, lined with fur and opening at the angles of the lips. Several forms live upon the arid plains of the Western United States and Mexico. The true pocket mice are small, grayish, nocturnal animals, that come out of their burrows only at night to gather seeds and the like, which they carry in their cheek-pouches into their holes and store there for winter use. Another genus includes the larger, brush-tailed, far-leaping kangaroo-rat (q.v.).

POCO, pō'kō (It., little). A term much used in music, as *poco animato*, rather animated; *poco forte*, abbreviated *pf.*, rather loud; *poco a poco* signifies by degrees, little by little; *poco a poco crescendo*, becoming loud by degrees; *poco a poco rallentando*, becoming slower by degrees.

PO'COCKE, or **POCOCK**, EDWARD (1604-91). An English Oriental scholar. He was born at Oxford, graduated B.A. from Corpus Christi College, Oxford, in 1622, and received priest's orders in 1629. He early turned his attention to Oriental studies and had the best teachers that England could supply. In the Bodleian Library he discovered a manuscript of the Syriac version of the New Testament, containing four epistles (II. Peter, II. and III. John, and Jude), which had been missing in the earlier editions, and published them under the title *Versio et notæ ad quatuor epistolas syriacæ* (Leyden, 1630). In 1629 he was appointed chaplain to the English 'Turkey Merchants' at Aleppo, and arrived at his post in October of the following year. He remained there for more than five years, during which time he mastered the Arabic language and continued the study of Hebrew, Syriac, Samaritan, and Ethiopic. He cultivated friendly relations with the natives and was extraordinarily successful in collecting valuable manuscripts. He performed the duties of his post faithfully, and in 1634, when the plague raged in Aleppo, remained in the town when others fled to the mountains. In 1636 Pococke returned to England to accept from Archbishop Laud an appointment as the first professor of a new Arabic 'lectureship' at Oxford. The following year he again went to the East to study and collect more manuscripts. For nearly three years he resided at Constantinople, returning to England in 1641. During the Civil War and the Commonwealth his connection with Laud and Royalist sympathies exposed him to much annoyance. His college presented him to the living at Childrey, Berkshire (1642), where his parishioners cheated him and quartered soldiers at the rectory. The revenues of the Arabic lectureship were illegally seized, but by the exertion of John Selden and other friends, Pococke was reinstated. He was made professor of Hebrew (1647), with a canonry, of which he was deprived in 1650, while allowed to retain his professorships through the unanimous interposition of all the heads of houses, masters, and scholars at Oxford. In 1655 a plan to deprive him of his living was defeated through the influence of John Owen and other enlightened men, who urged "the infinite contempt and reproach which would result from such treatment of a man whom all the learned, not of England only, but of all Europe, admired for his vast learning and accomplishments." During these troublous times Pococke steadily pursued his studies, and strove to fulfill all duties incumbent upon him, but professed that "to do anything that may ever so little molest the quiet of my conscience would be more grievous than the loss, not only of my fortunes, but even of my life." He published his great work, the *Specimen Historiæ Arabum*, at Oxford in 1649 (2d ed. by Joseph White, 1806). This work marks an epoch in Arabic studies, and all later scholars have borne testimony to its erudition and sound scholarship. Other works of the same period are the *Porta Mosis*, an edition of the six prefatory discourses of Maimonides on the

Mishna, with Latin translations and notes (1655); the *Contectio Gemmarum*, a Latin translation of the *Annals* of Eutychius (1658); and a treatise on *The Nature of the Drink Kauri or Coffee*, Described by an Arabian Physician (1659). He gave much assistance in the preparation of Walton's Polyglot (1657). At the Restoration he was reinstated in his canonry of Christ Church, and thenceforth lived in quiet and ease at Oxford, but with no abatement of his devotion to study. He published several works, the most important of which were his commentaries on the Minor Prophets (Micah and Malachi, 1677; Hosea, 1685; Joel, 1691). He died September 10, 1691. Pococke's life was written by the Rev. Leonard Twells and prefixed to his edition of *The Theological Works of the Learned Dr. Pococke* (2 vols., London, 1740).

POCOCKE, RICHARD (1704-65). An English clergyman and traveler. He was born at Southampton, and studied at Corpus Christi, Oxford. In 1725 he was appointed precentor of Lismore and in 1734 Vicar-General of the Diocese of Waterford and Lismore. The appointment was made during his absence, for from 1733 to 1736 he traveled through Europe to Greece. His passion for travel became established, and upon his return home he made tours through some of the southern counties of England, and came to be known as "Pococke the traveler." In 1737 he set forth upon a long journey to Egypt and the East, from which he returned in 1742, shortly afterwards publishing in folio *A Description of the East and of Some Other Countries*: vol. i., *Observations on Egypt* (1743); vol. ii., in two parts, *Observations on Palestine, or the Holy Land, Syria, Mesopotamia, Cyprus, and Candia* (1745). This work was dedicated to the Earl of Chesterfield, and earned for the author the Archdeaconry of Dublin (1755). In 1756 he was made Bishop of Ossory, and one of his first labors was the restoration of the beautiful cathedral church of Saint Canice in Kilkenny. He became interested in the study of Irish antiquities and wrote *An Account of Some Antiquities Found in Ireland* for the London Society of Antiquarians, which was published after his death in the second volume of the *Archæologia* (1773). Pococke made several journeys to Scotland, and in 1760, having prepared himself by extensive reading, he set out on a tour that led him as far as the Orkneys, from which he returned by the east coast, visiting, describing, and sketching nearly all the abbeys, ruins, and places of interest on his route. Between April and October he traveled 3391 miles on horseback. The accounts of his Scottish travels did not appear until brought out by the Scottish History Society, *Tours in Scotland, 1747, 1750, 1760*, edited, with a biographical sketch by Kemp (1887). Pococke's interests were not exclusively devoted to antiquarian research. He established the Lintown factory in 1763 to further the Irish linen trade, and left a bequest for its maintenance. As Pococke College it is still perpetuated under the Incorporated Society for Promoting English Protestant Schools in Ireland. In 1765 he was translated to the Bishopric of Meath. Accounts of his travels in England, Scotland, and Ireland were republished between 1888 and 1891.

PODAGRA. See GOUT.

PODARGE, pō-dār'jē (Lat., from Gk. ποδάργη, swift-footed). One of the Harpies (q.v.).

PODBIELSKI, pōd'bè-él'ské, THEOPHIL VON (1814-79). A Prussian general. He was born at Kopenick, studied at Liegnitz, and entered the army in 1831. He was quartermaster-general of the army in Schleswig and Holstein, held the same post in the war with Austria, after serving as director of the General Department of War, and is best known for his dispatches from the field in the Franco-Prussian war, when he was again quartermaster-general. Podbielski was appointed inspector-general of artillery after the close of the French campaign.

PODBIELSKI, VICTOR VON (1844—). A German officer and statesman, born at Frankfort-on-the-Oder. He was trained for the army in Berlin and in 1862 joined the Eleventh Lancers. During the Franco-German War he served on the general staff of the Tenth Army Corps, later acted as major-general of the Thirty-fourth Cavalry Brigade, and was promoted to be lieutenant-general in 1896. He entered the Reichstag in 1893 and allied himself with the Conservative Party, and in 1897 succeeded von Stephan as head of the Imperial postal service, distinguishing his administration by many reforms. In 1898 he was made Privy Councilor, and in 1901 he became Prussian Minister of Agriculture.

POD CORN. See MAIZE.

PODESTÀ, pō-dēs-tà' (It., power). A term applied to the chief magistrate in the mediæval States of Italy. The office of podestà appears to have been first instituted in the twelfth century, when the Emperor Frederick Barbarossa, having for a brief term reestablished the Imperial authority in Lombardy, placed officers with almost supreme power over the various towns. When the Lombards afterwards rose in rebellion against Frederick, the office was abrogated, but it was soon revived by themselves. As the chief cause of the appointment of the podestà was the jealousy that existed between the richer citizens and the nobles, he was usually a citizen of some neighboring State, who had formed no entangling alliances. During his term of office he was prohibited from cultivating any intimate connections in the city which he governed. The podestà usually held office for a year only, but occasionally his power became so great that he secured reelection during a succession of years and was the despotic ruler of the city.

PODGORZE, pōd-gōr'zhe. A town in the Crownland of Galicia, Austria, on the right bank of the Vistula, opposite Cracow (Map: Austria, F 1). It has brickyards, cement and leather factories, salt works, and a good trade in trimmed lumber and eggs. Population, in 1890, 13,100; in 1900, 18,100, mostly Poles, and more than one-third Jews.

PODIEBRAD, pō'dye-brád, GEORGE (1420-71). King of Bohemia from 1458 to 1471. He was born at Podiebrad in 1420, the son of a Bohemian noble, Herant of Podiebrad and Kunstatt. He adhered to the moderate party of the Hussites during the reign of Sigismund; but when, on the death of that monarch, the Catholic barons (1438) carried the election of Albert V. of Austria (II. of Germany), Podiebrad allied himself with the Utraquists, who offered the sovereignty of Bohemia to Casimir, brother of Ladislas III., King of Poland. From this time Podiebrad's influence gradually increased, and in 1444 he became the

leader of the party of Utraquists, and was made administrator of the realm during the minority of the child King, Ladislas Posthumus, the son of Albert. In 1448 he obtained possession of Prague, and in 1452 was acknowledged Regent by the whole of Bohemia. Ladislas Posthumus died in 1457, and in 1458 Podiebrad was chosen his successor, and was crowned May 7, 1459. He strove to bring about a peaceful settlement of the religious discussions that had desolated the land, and agreed secretly to lead the country back to the Roman Catholic Church. When, however, he failed to fulfill this promise, upholding the Utraquists, he was excommunicated by Pope Pius II. in 1463 and by the successor of that pontiff, Paul II., in 1466. The Catholics of Bohemia were incited to insurrection, and Matthias Corvinus (q.v.), King of Hungary, the son-in-law of Podiebrad, was induced to invade Bohemia. The Hungarians were surrounded at Wilimow, and forced to cease from hostilities. In spite of the magnanimity shown by Podiebrad on this occasion, Matthias acted falsely toward him, and in the following year had himself crowned King of Bohemia and Margrave of Moravia. Podiebrad instantly summoned the Bohemian diet, and proposed to the assembled orders that they should take Ladislas, son of Casimir IV., King of Poland, as his successor, while his own sons should merely retain the family possessions. By this means he obtained the Poles for allies; the Emperor Frederick III. also declared in his favor, while his Catholic subjects were reconciled to him, so that the Hungarians found it advisable to conclude a peace. Podiebrad died March 22, 1471. Consult: Jordan, *Das Königthum Georgs von Podiebrad* (Leipzig, 1861); Bachmann, *Böhmen und seine Nachbarländer unter Georg von Podiebrad* (Prague, 1878).

PODIUM (Lat., from Gk. *πόδιον*, *podion*, little foot, diminutive of *πούς*, *pous*, *foot*). In classic architecture, a continuous base or pedestal in the form of a wall not broken by steps like the base of a Greek temple, but distinguished, like an enlarged pedestal, merely by a base at the bottom and a corona at the top. It was generally used to support rows of columns, or as the base of a sepulchral or memorial monument. Its name was extended to the basement of the outer wall of the interior of an amphitheatre or circus.

PODOCARPUS (Neo-Lat., from Gk. *πούς*, *pous*, *foot* + *καρπός*, *karpos*, *fruit*; so called from the thick stalk which, unlike the case of other conifers, supports the fruit). A genus of trees of the natural order Conifere. The leaves, like those of the allied ginkgo tree, have a remarkable resemblance to the fronds of ferns. The species are natives of New Zealand and the South Sea Islands and the Indian Archipelago. Some of them are valuable timber trees, e.g. *Podocarpus cupressina*, of Java and the neighboring islands and the South Sea Islands, a beautiful species 50 or 80 feet tall, with spreading pendulous branches, and yellow wood that takes a fine polish. *Podocarpus Totarra*, the totarra or totarra pine, is the most valuable timber tree of New Zealand, in the southern parts of which country its trunk has been known to attain a diameter of 12 feet. Its wood is equal to the best Baltic pine in durability and for shipbuilding. The wood of *Podocarpus clata*, the gagali of the

Fijians, is peculiarly elastic. It abounds in Queensland and New South Wales, where it becomes 100 feet in height and two to three feet in diameter. The timber is free from knots, soft, close-grained, and easily worked, and is much used for cabinet and joiners' work. A shrubby species, *Podocarpus spinulosa*, also a native of Australia, produces an edible fruit. See DACRYDIUM.

PODOLIA, πόδω'lyá. A government of South-western Russia, bounded by the Government of Volhynia on the north, Kiev on the east, Kherston and Bessarabia on the south, and the Austrian Crownland of Galicia on the west (Map: Russia, C 5). Area, 16,240 square miles. The region is traversed from northwest to southeast by two ranges of hills separated from each other by the valley of the Bug. The Dnieper flows along the southwestern boundary. The climate is moderate, the annual temperature at Kamenetz-Podolsk, the capital, averaging 48.4°. Podolia has a rich black soil yielding considerable quantities of grain for export. Besides cereals there are raised tobacco and large quantities of sugar beets for the local sugar mills. The chief products of the house industry are textiles. In 1896 there were in Podolia about 5200 manufacturing establishments, with 28,500 employees and an output valued at more than \$19,000,000. The principal manufactured products are sugar (in the production of which Podolia is exceeded only by the Government of Kiev), spirits, flour, and tobacco. Population, in 1897, 3,031,500, including over 240,000 Roman Catholics, and nearly 400,000 Jews.

PODOPHYLLIN (from Neo-Lat. *Podophyllum*, from Gk. πούς, *pous*, foot + φύλλον, *phyllo*, leaf, so called because the five or seven divisions of the leaf bore a fancied resemblance to the foot of some animal). The name commonly given to the resin obtained by means of rectified spirit from the root of *Podophyllum peltatum*, or May-apple, a plant common throughout the United States. This resin, which occurs as a pale greenish amorphous powder, has (as well as the root from which it is derived) been introduced into the United States pharmacopœia. It is an active purgative, and seems to have the power of relieving the liver by exciting copious bilious discharges. As its activity seems to vary in different patients, it is better to begin with a small dose of half a grain, which may be combined with extract of henbane (hyoseyamus) to prevent griping. Podophyllin is very soluble in alcohol and moderately so in ether. *Picropodophyllin* is said to be the constituent to which the purgative properties of the resin are due.

PODOPHYLLUM (Neo-Lat., from Gk. πούς, *pous*, foot + ύλλον, *phyllo*, leaf). A genus of plants of the natural order Berberidaceæ. *Podophyllum peltatum*, called May-apple, mandrake (q.v.), hog-apple, and wild lemon, is a common perennial plant in moist woods of North America. Its solitary white flower in the axil of the two leaves is followed by an oval, smooth, yellowish, succulent, mawkishly sweet, subacid fruit, which is not generally considered agreeable.

PODSNAP, Mr. A character in Dickens's *Our Mutual Friend*, a type of a heavy British gentleman, perfectly satisfied with the ways of Providence, which represented exactly his own views. His wife was a bony, hard-featured

woman in a majestic headdress, and his daughter, whom he called 'the young person,' was a quiet, inoffensive girl.

POE, EDGAR ALLAN (1809-49). An American poet and prose writer, born in Boston, January 19, 1809. The grandson of a prominent patriot during the War of the Revolution, the son of an actor whose wife was his superior in charm if not in power on the stage, Poe shared for several years the wandering life and vicissitudes of his parents, but after his mother's early death was adopted by Mrs. John Allan, the wife of a business man of Richmond, Va. The boy's personality gave promise of fascinating qualities, and he was given the best educational opportunities within the reach of his adopted parents. He was sent to a good school in Richmond; was taken to England in 1815 and placed in the Manor House School in the neighborhood of London, amid surroundings which made a deep impression on his sensitive imagination. In one of his most striking sketches, "William Wilson," he recalled in vivid description the school, the village, and the old church to which the boys were paraded twice on Sunday. In 1820 the Allans returned to Richmond and Edgar read the classics and studied French under a pedantic Irish teacher, learning with great quickness, versatile, fond of reading, somewhat given to satirical comment on his fellows, agile and vigorous in movement and courteous in manner. In 1826 Poe entered the University of Virginia, which had just been established by Thomas Jefferson at Charlottesville on new and promising lines of organization and methods of work. In the schools of ancient and modern languages in which he studied, Poe gave his attention chiefly to Latin, Greek, Spanish, French, and Italian. Heavy drinking and card-playing for money were popular forms of dissipation among students, and Poe's life was not free from excesses. There is, however, no foundation for the reports of excessive indulgence in these vices; he seems to have been neither better nor worse than many of his contemporaries. At the end of the first session he won honors in Latin and French, but his irregularities offended Mr. Allan, and Poe was placed in his adopted father's counting-room. The work was very distasteful to him, and he soon made his escape from its drudgery to reappear in Boston, where his earliest volume, *Tamerlane, and Other Poems*, was brought out by an amateur publisher in 1827. The influence of Byron was then at its height, and Poe's work showed how sympathetically he had studied the English poet whose mastery of the lyric form has given him a foremost place among the singing poets. The verse in the little volume was notable neither for power nor promise of original thought, but it was full of poetic feeling, of sensitiveness to the melody of words, and of rich imagery. In May, 1827, Poe enlisted in the United States Army as a private soldier, served two years with fidelity, was honorably discharged, secured a reconciliation with Mr. Allan, and furnished more substantial evidence of his possession of original power by the publication of "Al Araaf" and other minor poems in Baltimore in 1829. Mr. Allan married a second time in October, 1830, having previously, by way of settling his wayward ward in life, secured for him an appointment to the Military Academy at West Point. Poe was then twenty-one

years of age, a ready French scholar, had read widely if not wisely, and was a good mathematician. He was, however, neglectful of his military duties, was often under arrest, and at the end of six months was dismissed from the Academy by court-martial. He was penniless and could no longer look to Mr. Allan for aid. In March, 1831, another volume from his hand appeared, this time in New York, under the title *Poems*. All the poems save six which had appeared in the previous volume were reprinted, with important changes in several instances, and six additional pieces were given to the public. Among the latter were "The Valley of Unrest," "The City in the Sea," "Lenore," "To Helen," and "Israfel." No poetry of kindred beauty had appeared in America, and in certain respects those remarkable poems have not been surpassed. They showed a wonderfully sensitive ear for verbal notation, a touch so delicate and sure that it may be described as magical, and an imagination at once sombre and beautiful. An artist by temperament and by imitation, Poe had no lessons to teach, no truths to enforce. He cared supremely for beauty for its own sake; and so completely did he master the resources of verse that he was able, by mere collocation of sound, to produce an almost hypnotic effect, to throw a spell over his readers the secret of which resides in the beguiling of the ear quite as much as in the awakening of the imagination.

The poet's activities were henceforth concentrated on the task of supporting himself with his pen—a task which was rendered exceedingly difficult, not by lack of opportunities or of friends, but by irregularities of life and a restive, sensitive, and capricious temperament. In Baltimore, where he next endeavored to secure a foothold, he found friends and made his first popular success by winning a prize of \$100 offered by *The Saturday Visitor*, a monthly literary journal, for the best prose story. The story selected by the judges was "A Manuscript Found in a Bottle." Poe was then living with his father's widowed sister, Mrs. Clemm, whose daughter Virginia, then eleven years old, he married two years later. In the meantime Mr. Allan had died without any recognition of his adopted son in his will, and the poet was at last compelled to face life with such resources as nature had given him. These were ample if they had been wisely directed and husbanded. He had proved himself a master of lyrical poetry and of the short story, and he was beginning to write criticism of a new order in America. He was also drinking too often and too freely, and his abnormally sensitive nervous organization was seriously affected and finally shattered by an indulgence which to men of more vigorous physique would have been of slight physical importance. The uncertainty of his life, the pronounced strain of melancholy in his temperament, the brooding intensity of his imagination, the weakness of his will, and the terrible strain of his wife's long illness contributed to make him the victim of a habit against which he fought at times with desperate courage, and for long periods with success. He was never, except for short periods, what is known as a dissipated man; but strong drink of any kind was a poison to him and the least indulgence prostrated him.

From Baltimore Poe removed to Richmond, which he always regarded as his home and where

he found congenial and helpful friends. As editor of *The Southern Literary Messenger* he secured the happiest conditions which he was to know. He was an indefatigable worker, producing stories, poems, and critiques with ease, and at this time with evident pleasure. To this period belong a number of his most characteristic tales of fantasy: "Berenice," "The Fall of the House of Usher," "Ligeia," "Eleonora," "The Masque of the Red Death." These tales were not without forerunners in other literatures, but they combined a quality of imagination, a skill in taking possession of the imagination of the reader, and a perfection of form which have given them a place by themselves in the literature of the world. They close in upon the mind, by a subtle use of suggestion and repetition, until a purely phantasmal world becomes real and abnormal figures take on the semblance of life. The skill with which the transition from the actual to the phantasmal is effected is the supreme triumph of Poe's art in fiction. The men and women who appear in these tales are all phantoms, without warmth, passion, character; they, and the realm in which they move, are stamped with unreality. Poe's great limitation lies in the narrowness of his range and the lack of deep-rooted vitality in the creatures of his imagination. He deals habitually with abnormal aspects of life and phases of experience. His landscapes, characters, incidents are all in the realm of fantasy. These characteristics place him in the ranks of the modern Decadents, whom he has deeply influenced; but he differs widely from the men who have followed his lead in the absolute purity of his thought and imagination.

In 1835 literature of high quality was being produced in the United States, but public taste was uneducated, and crude, sentimental, and cheap fiction was widely read. In the columns of *The Southern Literary Messenger* Poe began to print criticism of a kind and quality which was new to most American readers. He broke away entirely from the trammels of provincialism in taste and judgment, and applied to current writing the standards of the literature of the world. His handling of "Norman Leslie," a popular novel of the day, arrested attention by reason of its vigor, its sarcasm, its disclosure of a genuine gift for analysis and appraisal of literary values. The critic, it was evident, was not averse to the use of the keenest weapons, but used them for high purposes. He was bent on exposing literary pretension and breaking the influence of mediocrity in American letters, and he rendered a genuine service to sound taste and therefore to the development of good literature by his critical work. He lacked the spiritual insight of critics of the highest class, but he had wide acquaintance with the best in literature, rare power of analysis, and a very delicate sense of form. Above all, he was largely free from provincial prejudices and capable of judging a work of art on its merits. He recognized the genius of Hawthorne at the very start; he was quick to set its full value on Tennyson's early verse; he discerned the significance of Bryant, Lowell, and Cooper. His occasional failure to comprehend the spirit and method of a contemporary was most strikingly shown in his unfortunate attack on Longfellow, whom he accused of plagiarizing.

Poe had many opportunities, but his temperament made it impossible to establish comfortable and permanent working relations. In 1837, when a disastrous financial panic was at its height, he arrived in New York with very ambitious purposes, but with no resources. "The Narrative of Arthur Gordon Pym," published the following year, added nothing to his reputation and little to his income. The autumn of 1838 found Poe in Philadelphia, where he wrote two of his most characteristic pieces, "Silence" and "The Haunted Palace." The poem shows an ethical feeling which no other work from the same hand reveals. Two volumes made up of stories and sketches appeared in 1839, and contained some of the most original work which America has produced.

"The Fall of the House of Usher," "Ligeia," "William Wilson," and "Silence" exhibit Poe's power of invention, vividness of imagination, and skill as an artist at their best; and in perfection of form these prose pieces rank with "Israfel," "To Helen," and "The City in the Sea." To this period belong also those tales of ratiocination which are among the best of their kind and have borne fruit in an abundant harvest of similar or imitative stories. "The Gold Bug," "The Purloined Letter," "The Mystery of Marie Roget," and "The Murders of the Rue Morgue" are on a lower order of imagination than the tales of fantasy, but they are marvelous pieces of invention.

During this period Poe was undergoing the torture of uncertainty with regard to his wife, whom he devotedly loved, and who was continuously and often desperately ill. Under this strain his power of resistance grew weaker, he yielded more easily and frequently to the craving for stimulants, and his unusual power of concentration gradually relaxed.

The position of editor of *Graham's Magazine*, in which he had revealed editorial ability of a high order, was given up or lost, and in 1844 Poe returned to New York with very little money and with a great sorrow impending in the near future. He was still, however, to achieve some of his most striking successes. In 1845 "The Raven," which gave him his immense popular reputation, appeared, and was followed by "The Bells" and "Ulalume." No American poems are more widely known, and in none is his marvelous command of the subtle resources of sound, his magical use of vowels, of repetition, of parallelism, so skillfully used to convey definite and striking effects. His collected poems were published at this time under the title, *The Raven, and Other Poems*, and in the preface to the collection is a piece of autobiography. "Events not to be controlled," he wrote, "have prevented me from making at any time any serious effort in what, under happier circumstances, would have been the field of my choice." He was then living in a cottage at Fordham, near New York; and there, in January, 1847, his wife died, and the poet was prostrated by a long illness. He was cared for by friends and finally recovered a degree of strength, but he was really a shattered man. He wrote "Eureka: A Prose Poem," marked by his characteristic inventiveness, put the finishing touches on "The Domain of Arnheim," and delivered a few lectures; but both his mind and his will bore traces of his great suffering. In June, 1849, he went to Richmond, was ill as the result of excesses in Philadelphia, was

shown much kindness and recovered something of his old spirit in the capital of Virginia. Late in September he started to return to New York. The story of the next few days will never be clearly told; but on an afternoon in the week following his departure from Richmond he was found in a drinking-place in Baltimore, taken to a hospital in an unconscious condition, and died four days later.

Of the three forms of Poe's literary activity his criticism, while of high importance at the time, is of least value; his prose tales have taken their place in the literature of the world by reason of their originality of motive and their finished art; while his poetry remains the most distinctive expression of his genius. In two important studies, "The Poetic Principle" and "The Rationale of Verse," he declared that truth gives expression to the intellect and passion to the heart, while beauty is the language of the soul. Beauty is, therefore, the highest form of creative activity; passion and truth are involved in it, but its chief aim is to produce a definite and convincing impression of its own nature by stimulating the imagination. He defined poetry as "the rhythmical creation of beauty," and laid down the law that beauty is essential to lyrical perfection in the phrase "a long poem does not exist." He also held that a marked quality of metre or rhythm ought to characterize all verse.

BIBLIOGRAPHY. Numerous editions of Poe's work have appeared since his death. That of Griswold (2d ed., 4 vols., New York, 1856) is prefaced by a biography which later writers consider prejudiced to the point of calumny; and the biography in the Stoddard edition (6 vols., new ed., New York, 1895), while deprecating Griswold's extreme view, is also biased. The Diamond edition (Boston, 1874) has a sketch by Gill. Later editions are by Ingram (2d ed., 4 vols., Edinburgh, 1880; New York, 1894); Stedman and Woodberry (10 vols., Chicago, 1895), a scholarly and complete edition; and the Virginia edition by Harrison, with notes by Stewart (17 vols., Boston, 1902), in which is included, in addition to the complete works of the poet, all the obtainable information as to his life, and a full bibliography. Poe's *Tales* have been translated into French by Baudelaire and are in his *Œuvres complètes*, vols. v.-vii. (Paris, 1878-82). There are also German and Spanish translations. The *Poems* have been published separately with memoirs by Hannay (London, 1865), Blanchard (ib., 1857), and Briggs (New York, 1859). Of the numerous biographies, Whitman, *Edgar Allan Poe and His Critics* (New York, 1860); Gill, *Life of Edgar Allan Poe* (5th ed., ib., 1880); and Ingram, *Edgar Allan Poe: His Life, Letters, and Opinions* (2d ed., London, 1886), are answers to Griswold's assertions. The *Life* by Didier (New York, 1877) is not entirely trustworthy. There are essays by Baudelaire prefixed to volumes v. and vi. of his *Œuvres complètes*, above mentioned, and by Stedman, in *Poets of America* (New York, 1880). The most critical *Life* is by Woodberry, in the "American Men of Letters Series" (Boston, 1885). A selection from Poe's correspondence, edited by Woodberry, appeared in the *Century Magazine*, vol. xxvi. (New York, 1894).

POE, ORLANDO METCALFE (1832-95). An American soldier, born at Navarre, Ohio. He graduated at West Point in 1856, and entered the

corps of topographical engineers. In 1861 he served for a time as chief engineer of the Department of Ohio, but later was made colonel of the Second Michigan Volunteers, and in 1862 took part in the Virginia and Maryland campaigns. On November 29th he was made brigadier-general of volunteers. The next spring he was transferred to the West as chief engineer of the Central District of Kentucky, and was Burnside's chief engineer during the defense of Knoxville (November 18-December 4, 1863), when he earned the brevet of major in the Regular Army. In 1864 he was appointed chief engineer of Sherman's army, participating in the invasion of Georgia and the campaign which ended with the surrender of General J. E. Johnston. He was brevetted brigadier-general in the Regular Army in 1865, and was commissioned colonel of engineers in 1888. After the Civil War he was for a number of years secretary of the United States Board of Lighthouse Commissioners, and had charge of the construction of many important river and harbor works, among them the Spectacle Reef and Stannard Rock Lighthouses and the great lock on the Sault Ste. Marie.

PŒCILE (Lat., from Gk. ποικιλῆ, *poikilē*, variegated). The name given, because of the paintings which adorned it, to a famous *stoa*, or portico, in Athens, from which the Stoics (q.v.) were named.

PŒNULUS (Lat., the young Carthaginian). A comedy by Plautus, imitated from the *Καρχηδόβιος* of Menander and produced in B.C. 189. The chief character is a Carthaginian who is stolen at an early age. He becomes enamored of one of two girls who eventually turn out to be his cousins. The play contains a famous Phœnician passage in Latin characters.

POERIO, pŏ-ā-rĕ-ō. CARLO. Baron (1803-67). An Italian patriot. He was born at Naples, December 10, 1803. In 1828 he joined the liberals of Naples and took part in the conspiracy of Avellino, for which he was imprisoned for a long time. He was concerned in the abortive attempt of 1847, but was discovered, and after the movement at Reggio was sent back to prison. The revolution which broke out at Palermo, January 12, 1848, set him at liberty, and he immediately gave himself to the organization of the famous demonstration of January 27, 1848, which brought about the Constitution of February 10th. Poerio was nominated director of police and Minister of Public Instruction; but he soon resigned. He was chosen Deputy to the Parliament. In 1849 the Government made extraordinary efforts to convict him of conspiring against it, but no valid case was made, and on the testimony of a suborned witness he was sentenced to twenty-four years' imprisonment. In January, 1859, Poerio and other political prisoners were put on board of a vessel in order to be transported to South America, but were transferred to an American ship, which landed them at Cork, whence they returned, by London, to Turin. In the following year Poerio was elected Deputy from Tuscany and took his seat in Parliament. When Garibaldi (q.v.) had driven out the Bourbon dynasty, Poerio returned to Naples. He became a member of the Privy Council, and subsequently vice-president of the Parliament. He died at Florence.

POETASTER, THE. A comedy by Ben Jonson (1601), attacking Marston and Dekker, to

which they retorted with *Satiromastix*. The scene is Rome in the time of Augustus; Marston appears as Crispinus, Dekker as Demetrius, and they are punished for conspiracy against Horace, representing Jonson.

POET AT THE BREAKFAST TABLE. **TIT.** A series of essays and poems by Oliver Wendell Holmes, contributed to the *Atlantic Monthly*, in 1871. These delightful sketches, in the vein of the *Autocrat* and the *Professor*, differ only in the seriousness of tone and subject.

POETICS (Gk. περί ποιητικῆς, *peri poiētikēs*). A fragmentary treatise by Aristotle on the philosophy of art, and especially of poetry. All we have of it (and possibly all that was ever written) is the discussion of epic poetry and the tragic drama, fortunately enriched with many allusions to the other arts; but restricted as it is, this treatise is unquestionably the most important work on criticism ever written, intrinsically as well as historically. Art, in Aristotle's conception, is 'imitation of life,' and its purpose is to give pleasure. This doctrine can be fully understood only in the light of Aristotle's metaphysical conceptions. He defines life as action or as an activity, and undoubtedly has in mind what elsewhere he calls the formal and moving causes, corresponding very closely to Plato's 'Ideas;' the 'imitation,' therefore, has a far subtler meaning than first appears, referring to the instinctive idealizations which underlie artistic embodiments, and form the essence of the artist's effort. Again, pleasure as the purpose of art must be understood to refer only to the finer satisfactions of taste; in no sense are gross enjoyments intended. Poetry, Aristotle held, appears as a result of a natural instinct and of native love of rhythm. At the same time the poet must have the "gift of metaphor," and this comes "not by art, but as a happy gift of nature." Perhaps the most acute of Aristotle's æsthetic theories is his explanation of the office of tragedy. This he finds to be a purgation of the passions, *katharsis*, through terror and noble pity. It is an exercise of the emotions in moderation, and so a relief of the tendency to emotional expression which men naturally have, without the wrack and strain which extreme emotion incurs. Hence it is akin to physical purgation, and is further a kind of pleasure because it contributes to that general temperance which was the Greek ideal of excellence. Consult: Butcher, *Aristotle's Theory of Poetry and Fine Art, with a Critical Text and Translation of the Poetics* (3d ed., New York, 1903).

POET LAUREATE. See LAUREATE, POET.

POETRY. See literatures of the various nations, as ENGLISH, FRENCH, GREEK, INDIAN, PROVENÇAL, etc. See, also, EPIC POETRY; LYRIC POETRY; PASTORAL POETRY; VERSIFICATION; RHYME; BLANK VERSE; EPIGRAM; MADRIGAL; SONNET; BALLAD; BALLADE; MINSTREL; TROUBADOUR; MEISTERSINGER; MINNESINGER. See, too, individual poems, such as the MAHABHARATA; VEDA; BEOWULF; ROLAND; NIBELUNGENLIED; VOLSUNGER SAGA, etc.

POETRY, SPASMODIC SCHOOL OF. A name sometimes applied to certain English authors of the nineteenth century whose writings are strained and unnatural in style. Of this class the best known are Philip James Bailey,

Alexander Smith, Sydney Dobell, and Gerald Massey (q.v.).

POETS' CORNER. The popular name given to a part of the south transept of Westminster Abbey containing the tombs and memorials of a number of Englishmen eminent in letters. The memorials include those of Chaucer, Dryden, Milton, Shakespeare, Spenser, Addison, Ben Jonson, Macaulay, Wordsworth, the American Longfellow, and others.

POEY, pŏ'a, **FELIPE** (1799-1891). A Cuban naturalist, born in Havana. In 1826 he went to Paris, where he studied zoölogy and aided in founding the Entomological Society of France. In 1833 he returned to Havana and devoted himself to the study of Cuban fauna, particularly fishes, of which he discovered many new species. In 1842 he was appointed professor of comparative anatomy and zoölogy at the University of Havana, a position which he held until his death. The most important of his publications are: *Memorias sobre la historia natural de la Isla de Cuba* (1860); *Reportorio fisico-natural de la Isla de Cuba*; and *Enumeratio Piscium Cubensium* (1875). His greatest work, *Ictiologia Cubana*, was still in manuscript at the time of his death.

POGE, CAPE. See CAPE POGGE.

POGGE, pŏ'ge, **PAUL** (1839-84). A German explorer of Africa, born at Ziersdorf, in Mecklenburg. In 1874 he joined Hoyer's expedition, and in December of 1875 alone reached Musamba, the capital of Muata Jamvo, the farthest point inland reached at that time by an explorer of the German Company. In 1880, with Wissman, he set out to explore the southern basin of the Congo. They separated at Nyangwe in 1882, and Pogge established a station near Mukenge. He died at Loando just as he was starting back to Europe. He wrote *Im Reiche des Muata Jamvo* (1880).

POGGENDORF, pŏg'gen-dŏrf, **JOHANN CHRISTIAN** (1796-1877). A German physicist, chemist, and editor. He was born at Hamburg, studied pharmacy, chemistry, and physics, and was connected with the University of Berlin from 1840 until his death, serving as professor from 1834. In 1838 he became a member of the Berlin Academy of Sciences. His chief discoveries were in connection with electricity and magnetism, but he is best known perhaps for the fact that from 1824 he edited the *Annalen der Physik und Chemie*, to which he contributed many important memoirs. In connection with Liebig and Wohler he prepared the *Handwörterbuch der Chemie* (Brunswick, 1837-51). He also published the *Lebenslinien zur Geschichte der exakten Wissenschaften* (Berlin, 1853), and *Biographisch-literarisches Handwörterbuch zur Geschichte der exakten Wissenschaften* (Leipzig, 1858-63, 2 vols.), subsequent editions of which have been issued. The *Geschichte der Physik*, edited by W. Barenten, was published in 1879. A biography of Poggendorf will be found in vol. elx. of the *Annalen*.

POGGIO BRACCIOLINI, pŏd'jŏ brä'chŏ-lĕ'nĕ, **GIOVANNI FRANCESCO** (1380-1459). A distinguished Italian scholar and author in the Renaissance period. He was born at Terranuova, near Florence, and after studying under John of Ravenna and Manuel Chrysoloras became a

copyist of manuscripts. His skill in that pursuit attracted the attention of the leading Florentine scholars, and at the age of twenty-two he entered the service of Pope Boniface IX. as Apostolic Secretary. He served in the same capacity under the seven succeeding popes (1404-53), attended the Council of Constance in 1414, and was present at the trial and martyrdom of Jerome of Prague, of which he wrote an almost sympathizing account. For the most part, however, he seems to have cared little for the important political and ecclesiastical movements of the period, and is remembered chiefly for his persevering and successful researches in various European monasteries where masterpieces of classic literature were lying unknown. Among the manuscripts he thus recovered were those of Quintilian (complete), the great philosophic poem of Lucretius, *De Natura Rerum*, seven orations of Cicero, twelve plays of Plautus, the commentaries of Aconius Pedianus, the history of Ammianus Marcellinus, Petronius, the *Dialogus* and *Germania* of Tacitus, and the fragment of Suetonius, *De Grammaticis et Rhetoribus*. Among his own works, all of which are in Latin, are a collection of *Letters* (1437); various moral essays, including *De Nobilitate Dialogus* and *De Varietate Fortunæ*; *Historia Florentina*, written in imitation of the style of Livy; and his most famous work, *Liber Facietiarum* (ed. by I. Liseur, Paris, 1878), a collection of violent and often indecent diatribes against the monks and clergy. The most scurrilous are those against Valla and Filelfo, with whom he was engaged in a long and bitter controversy. His works contain lively descriptions of the life and customs of various European countries, and valuable notes on the remains of antique art in Rome. He spent his last years at Florence, where he was chosen Chancellor. The material for the collection of French tales *Cent nouvelles nouvelles* (q.v.) was taken in part from the works of Poggio. His statue in the Cathedral of Florence is the work of Donatello. Consult the *Life* by Shepherú (Liverpool, 1802), and Symond's *Renaissance in Italy*.

POGO'DIN, MIKHAIL PETROVICH (1800-75). A Russian historian and archaeologist. Appointed professor at the Moscow University in 1830, he resigned in 1844 to devote himself to literature and the study of archaeology. His collection of Russian antiquities was bought by the Government. He published in 1841-56 a literary and political periodical called *The Mŏscovite*, in which he advocated Pan Slavism. His efforts in various kinds of literature are of little importance. Several monographs on special periods of Russian history, with his unfinished *Russian History* (7 vols., 1846-59), which is important for the material gathered, are his chief works of value.

POGY. The menhaden (q.v.).

POHL, pŏl, **RICHARD** (1826-96). A German writer on music. He was born in Leipzig, studied at Chemnitz and Karlsruhe, at Göttingen and Leipzig, taught in Gratz, and then devoted himself to music, living in Dresden (1852-54), in Weimar (1854-63), and in Baden-Baden from 1863 till his death. He edited the *Badeblatt* and (1856-60) *Anregungen für Kunst und Wissenschaft*. His musical critiques, some of which were published under the name *Hoplit*, did much to bring into favor the 'new German' school of

music. Pohl's chief works include: *Akustische Briefe* (1853); *Baireuther Erinnerungen* (1877); *Autobiographisches* (1881); *Richard Wagner* (1883); *Franz Liszt* (1883); *Hektor Berlioz* (1884); *Die Höhenzüge der musikalischen Entwicklung* (1888), as well as poems.

POHLE, pō'le, LEON (1841—). A German genre and portrait painter, born at Leipzig. He studied at the Dresden Academy (from 1856), then at Antwerp, under Van Lerius and under Pauwels at Weimar, and was appointed professor at the Dresden Academy in 1877. Having at first cultivated genre and history, he confined himself afterwards more and more to portraiture, and in this line produced such fine examples as the portraits of Ludwig Riecher (1872, Leipzig Museum, and 1880, National Gallery, Berlin), of the painter Karl Peschel (1880, Dresden Gallery), of the sculptor Hähnel, and of Baron Tauchnitz (both in the Leipzig Museum). Of his genre scenes, the Berlin Gallery contains an "Elegy," and the Dresden Gallery "Ecole Torniamenti."

POI. A fermented food product made from the starchy root of *Colocassia antiquorum*. It is very popular in the Hawaiian Islands. See Cocco.

POINCARÉ, pwān'ká'rā', JULES HENRY (1854—). A French mathematician and physicist, born at Nancy. He entered the Ecole Polytechnique in 1873, but left two years later to take up work in the School of Mines. He became an engineer in 1879, and in the same year doctor of sciences. In 1881 he was called to Paris, where in 1886 he became professor of mathematical physics and calculus of probabilities in the Faculty of Sciences. At the death of Tisserand (1896) he changed this chair for that of celestial mechanics. In 1887 he was made member of the Academy of Sciences at Paris, and after 1893 was a member of the Bureau of Longitudes (after 1898 its president). In 1889 he obtained the prize awarded by King Oscar of Sweden for a work on the problem of the three bodies (q.v.). Poincaré has become known as one of the greatest mathematicians produced by France in the last century. A disciple of Cauchy, he has carried out the investigations of the latter along the various lines of the theory of functions, and he has also applied his remarkable mathematical powers to profound researches in the domain of physics. He has introduced into mathematics a new class of transcendents, analogous to, but more general than, the elliptic functions, which he has named the Fuchsian functions in honor of Immanuel Fuchs (q.v.). He has also introduced in connection with these functions a new class of groups, also called Fuchsian. He has contributed to the theory of non-Euclidean geometry, to the theory of differential equations, and to various branches of higher algebra.

His works include: *Les méthodes nouvelles de la mécanique céleste* (3 vols., 1892-99); *Calcul des probabilités* (ed. by Quiquet, 1896); *Capillarité* (ed. by Blondin, 1895); *Cinématique et mécanismes potentiels et mécanique des fluides* (ed. by Guillet, 1899); *Electricité et optique* (2 vols., 1890-91); *Thermodynamique* (ed. by Blondin, 1892); *Leçons sur la théorie mathématique de la lumière* (2 vols., 1889-92); *Leçons sur la théorie de l'élasticité* (ed. by Borel and Drach, 1892); *Les oscillations électriques* (ed. by Maur-

rain, 1894); *Théorie analytique de la propagation de la chaleur* (ed. by Rouyer and Baire, 1895); *Théorie des tourbillons* (1893); *Théorie du potentiel Newtonien* (ed. by Le Roy and Vincent, 1899). Part of these works form his *Cours de physique* (13 vols., 1890). He has also published important memoirs on mathematics and physics in the *Journal des mathématiques pures et appliquées*, the *Journal de l'Ecole Polytechnique*, the *Transactions of the Philosophical Society of Cambridge*, *Scientia*, the *Acta Mathematica*, the *Mathematische Annalen*, and many other leading mathematical journals.

POIN'CIA'NA. A tropical tree. See C.ESALPINIA.

POIN'DEXTER, GEORGE (1779-1853). An American politician, born in Louisa County, Va. He studied law and began practice in Milton, Va. In 1802 he went to the Mississippi Territory, and in 1803 was appointed Attorney-General by Governor Claiborne. In 1806 he was in the Territorial Legislature, and prosecuted Aaron Burr when the latter was arrested in 1807. This year he was also elected delegate to the United States House of Representatives, and served two terms. In 1813 he was appointed United States judge of the Territory. In 1817 he presided over the committee to prepare a Constitution for the State, and was chosen its first Representative in Congress. Here he distinguished himself by his defense of General Jackson's course in Florida. In 1819 he was chosen Governor of the State and while in office prepared *The Revised Code of Laws of Mississippi* (1824). In 1830 he was appointed and then elected to fill out an unexpired term as United States Senator. Meanwhile his admiration for President Jackson had cooled, and he was even charged with complicity in the attempted assassination. He voted for Clay's resolution of censure for the President on account of the removal of deposits from the Bank of the United States, much to the surprise of his constituents. In 1835 he was defeated for reelection. Poindexter had great ability, but was violent, arrogant, and obstinate. As a result of one of his quarrels he killed Abijah Hunt in a duel (1811), in which he was accused of firing before the word.

POINDING, pind'ing (from *poind*, Scotch dialectic form of *pound*; connected with AS. *ge-pyndan*, Eng. *pind*, to shut up, impound, and with *pond*). In Scotch law, a method of satisfying a claim, under process of law, by seizing and selling the debtor's goods. Where a creditor has a claim which is considered a lien or burden on land, he may obtain a writ or warrant, known as a *debitum fundi*, authorizing the attachment and sale of such movables (q.v.) or chattels on the land as belong to the debtor. This is called 'real poinding.' 'Personal poinding,' or seizing any other personal goods of a debtor, is authorized by a special writ issued by an inferior judicial officer. Beasts of burden, plow animals, and agricultural implements must not be seized until all other goods of the debtor are exhausted. Another species of poinding is permitted corresponding to the English and American proceeding of 'impounding' cattle. (See POUND.) The proceedings for the collection of debts above described correspond to the English proceeding of distress and the American processes of attach-

ment and execution. See ATTACHMENT; DISTRESS; EXECUTION.

POINSETT, JOEL ROBERTS (1779-1851). An American diplomatist and official, born at Stotesburg, S. C. He was educated at Dr. Timothy Dwight's school at Greenfield, Conn., and in Great Britain, studying medicine at Edinburgh and military science at Woolwich. His father persuaded him to study law, but before returning to America Poinsett traveled extensively through Europe and Asia. In 1809 he was sent as United States Commissioner to South America to investigate the chances of the revolting provinces for independence. While he was in Chile the Spanish authorities of Peru, hearing that war had been declared against the United States, seized American merchantmen, but were forced by Poinsett at the head of Chilean soldiers to return them with apologies. On his return to America Poinsett was elected to the South Carolina Legislature, and strongly advocated internal improvements. From 1821 to 1825 he sat in the United States Congress as a Federalist, and advocated sending assistance to the South American republics. In 1822 he had been sent as special minister to Mexico, and from 1825 to 1829 was minister to that country. When the issues of nullification (q.v.) came to the front in South Carolina (1830-32) he became prominent in the 'Union Party' and opposed the idea of nullification vigorously. From 1837 to 1841 he was Secretary of War in Van Buren's Cabinet, and in 1840 secured the passage of the militia reorganization bill. He wrote many orations and essays, and founded an academy of fine arts in Charleston. He published *Notes on Mexico, Made in 1822; with an Historical Sketch of the Revolution* (1824).

POINSETTIA. A species of Euphorbia. See SPURGE.

POINT DE GALLE, pwān de gāl, or GALLE. The oldest commercial port of Ceylon, situated at the southwestern end of the island. 56 miles southeast of Colombo (Map: India, D 7). It lies at the foot of a range of rocky hills and is well laid out. The European town, inclosed by fortifications constructed during the Dutch occupation, contains a fine church and many other public buildings. The town has a good harbor, but it has lost its former commercial importance, and even the cocoanuts which are obtained chiefly in its vicinity are shipped to Colombo by rail. Point de Galle is the seat of a United States consular agency. The town was taken by the Portuguese in 1518 and attained commercial importance on account of the cinnamon monopoly. In 1642 it came into the hands of the Dutch, by whom it was strongly fortified. It passed to Great Britain in 1796. Population, in 1891, 33,590; in 1901, 37,326.

POINTE-À-PITRE, pwān'tá'pé'tr'. The principal seaport and largest town of the French West Indian island of Guadeloupe, situated about 20 miles northeast of the capital, Basse-Terre (Map: West Indies, R 6). It is a new town, built on the site of an old town destroyed by fire and earthquake, and is surrounded by a marshy district. It has a cathedral and a museum. The harbor is spacious and safe. It exports cocoa, sugar, and vanilla. It is in direct communication with France. The population is 16,500.

POINTER. A dog. See FIELD DOG.

POINT LEVI, là-vé'. A river port in Quebec, Canada. See LEVIS.

POINT PLEASANT, BATTLE OF. In American history, a battle fought October 10, 1774, at the mouth of the Great Kanawha River, in Virginia (now West Virginia), between about 1200 Virginians under Andrew Lewis and about 1000 Indians under the Shawnee chief Cornstalk, the former gaining a decisive victory, which closed 'Lord Dunmore's War.' Lewis had arrived at this point on October 6th, and had encamped to await the coming of Lord Dunmore, who was to join him with a force of 1000. Early on the 10th, however, Lord Dunmore having appointed another rendezvous, Lewis was preparing to cross the Ohio, when he was suddenly attacked by the Indians. After a fierce contest, lasting all day, each side fighting, Indian fashion, behind trees and boulders, the whites finally won. The battle has been regarded as one of the most stubborn and evenly contested ever fought between Indians and white men. Each side lost fully a fifth of its number, the loss of the whites being 75 killed and 150 wounded, Col. Charles Lewis being among the former; while that of the Indians, probably fully as great, was never accurately determined. The victory forced the Indians to make a treaty relinquishing to the whites a large tract of land south of the Ohio, while it kept the Northwestern tribes relatively quiet during the early part of the Revolution, threw open the Ohio route to Kentucky, and inspired the pioneers with renewed confidence. There is little historic basis for the claim, frequently made, that this should be regarded as the first battle of the Revolutionary War.

POINT D'APPUI, pwān' dāp'pwé' (Fr., point of touch). In military tactics, one of the points previously agreed upon where troops may rally or rendezvous, after an extended or scattered movement. In attack formation, it may be the point, or points, from which the actual attack is commenced.

POINTS OF THE ESCUTCHEON. See HERALDRY.

POIRÉ, pwá'rá', EMMANUEL (1858—). A French caricaturist, better known by his pen name, Caran d'Ache. He was born in Moscow, Russia. His first drawings were published in the *Chronique Parisienne*. Afterwards his work appeared in *Tout Paris*, *Vie Parisienne*, and various other publications. His drawings have been gathered in albums, such as *Psst* (1898), which contains his Dreyfus sketches. He is particularly happy in his portrayal of soldiers, and is a keen observer and an original draughtsman. He is said to have created the 'histoire sans légende' in France. His illustrations include those done for *La comédie politique* of Millaud. He also won much success with his pantomime *L'Épopée*, which celebrated the victories of Napoleon.

POISON (OF., Fr. *poison*, from Lat. *potio*, drink, *potio*, from *potare*, to drink). In law, any chemical which, if taken or injected into the human body, will cause some bodily harm or death. In most States the sale of poisons is regulated by statute. Common regulations are to require bottles or other receptacles containing poison to be plainly labeled 'Poison,' in addition to the scientific name of the drug, and to prohibit druggists from retailing certain poisons

POISONOUS PLANTS

without physicians' certificates or prescriptions for their use.

Poisoning is the crime of administering poison to a human being with intention to cause death or bodily harm. It is punished according to the result, as in other cases where one person is willfully or maliciously injured by another. Physicians may administer poisons as medicines in their discretion. Consult the authorities referred to under MEDICAL JURISPRUDENCE. See CRIME and the authorities there referred to.

POISON ALDER. See SUMAC.

POISON IVY. See IVY; SUMAC.

POISON OAK (*Rhus Toxicodendron*). An American shrub, feared because of its reputed poisonous qualities, said to be due to a non-volatile oil which produces itching, reddening, and swelling of the skin of certain individuals, but not of others. Saturated alcoholic solution of lead acetate (sugar of lead) is recommended as an antidote. See IVY; SUMAC.

POISON OF SERPENTS. See SNAKE; RATTLESNAKE; VIPER.

POISONOUS INSECTS. See INSECT, paragraph *Poisonous Insects*.

POISONOUS PLANTS. Vegetable substances reputed injurious to man and animals. This seemingly loose definition is rendered necessary because of the transitional state in which plants are with respect to popular belief, as the following facts sufficiently indicate: (1) Many plants formerly dreaded as violent poisons are now considered innocuous or inert, others unpleasant or unwholesome, still others edible, and some have even taken rank among our most important vegetable foods. (2) Certain plants, even among those used for food, are so feared by individuals that unpleasant physiological effects are observed whenever they are eaten, or in some cases even handled. These phenomena cannot, however, be attributed to the plants because they follow only in exceptional cases, and in these fear more or less well defined is an invariable precursor. (3) Still other species which in the individual have never produced untoward effects are, by hasty people, suddenly arraigned and condemned because of some observed physiological phenomenon supposedly due to eating or handling them. (4) Certain plants which produce no external effect upon or are even eaten freely by animals are feared by some people who consequently exhibit the phenomena they apprehend. (5) Lastly, immoderate indulgence of the appetite with many plants, probably with any plant, even one considered highly nutritive, may be followed by unpleasant or apparently even more serious symptoms; but these are the natural penalty for, and can legitimately be charged only to greed or gluttony.

Probably the best example of the first class is the tomato, which during the nineteenth century rose from the ranks of so-called poisonous plants, passing to the highest stage through the other stages indicated. As instances of the second and third groups the strawberry and celery are perhaps the best known; certain persons are afraid to eat the former, and others to handle the latter. Probably no plant so well represents the fourth category as does poison ivy, which is eaten

with apparent relish by horses, goats, and some other animals, but is feared by perhaps more people than any other American plant. Instances in the last group are of frequent individual experience.

Judging from these and other data that what is true of the past will be true in future, it is safe to predict that the plants now regarded as noxious will also be freed from the obloquy with which they seem to be smirched.

For descriptions of the plants illustrated on the accompanying Plate, see generic or common name titles.

POISONS. See TOXICOLOGY; ANTIDOTE.

POISON SUMACH. See DOGWOOD.

POISSON, pwä'sôn', SIMÉON DENIS (1781-1840). A French mathematician, physicist, and astronomer. He early took up the study of the descriptive geometry of Monge. At the age of seventeen he entered the polytechnic school at Paris, where he soon attracted the attention of his instructors, notably of Lagrange. He held various positions as examiner and professor in this institution for nearly forty years. He was also professor of mechanics on the Faculty of Sciences, member of the Bureau of Measures, and member of the Council of Public instruction (1820). He was made Baron by Napoleon and in 1837 became a peer. His scientific works and memoirs number over 300, and are devoted to mathematics, physics, and astronomy. The work enjoying the widest circulation is his *Traité de mécanique* (2 vols., 1811; 2d ed. 1833; German trans. 1835-36). His other notable works are: *Theorie mathématique de la chaleur* (1835; supplement 1837); *Recherches sur la probabilité des jugements en matière criminelle et en matière civile* (1837). His important memoirs on definite integrals and their applications to physics, on calculus of variations, and on probability were published in *Journal de l'Ecole Polytechnique* (1802-39); *Mémoires de l'Académie* (1811-43); *Connaissance des Temps* (1819-27); and in numerous other journals. Arago's works, volume ii., contain a complete list of Poisson's productions.

POISSY, pwä'sé'. A small town of France, in the Department of Seine-et-Oise, situated 10 miles northwest of Paris. It has a fine church which is one of the best examples of the transition style of the twelfth century. Poissy is the birthplace of Saint Louis (1215), and here in 1561 a famous religious conference was held between Catholics and Protestants. The town has important iron foundries. Population, in 1900, 7506.

POITIERS, pwä'tyá'. The capital of the Department of Vienne, and formerly of the Province of Poitou, in Western France. It is situated on a plateau-like peninsula formed by the junction of the Clain and the Boivre rivers, and on the Orleans Railroad, 58 miles southwest of Tours (Map: France, G 5). It is an old town with narrow, crooked, and ill-paved streets. Although it is a railroad junction, its commerce and industries are not very important. It is chiefly interesting on account of its ancient and mediæval remains and associations. It is preëminently a city of churches and ecclesiastical institutions. The cathedral is a Gothic-Romanesque structure of the twelfth century, with an imposing inte-

rior, but a rather heavy façade. There are several very old and interesting churches, such as the Temple Saint Jean, a baptistery built in the seventh century, and one of the oldest Christian monuments in France; the Church of Notre Dame la Grande, a Romanesque building of the eleventh century, with an elaborately decorated façade; and the Church of Sainte Radegonde, founded in the sixth century, rebuilt in the eleventh century, and containing the sarcophagus of the saint. Among the noteworthy buildings and places are the fine modern Hotel-de-Ville and the Parc de Blossac; the latter, situated at the southern end of the town, is bordered by mediæval ramparts and commands a fine view. At the northern end, near Pont Joubert, is a colossal gilded statue of Notre Dame des Dunes. Poitiers has a university with faculties of law, science, and philosophy, and a preparatory school of medicine and pharmacy. The municipal library contains 65,000 volumes and 460 manuscripts. There are museums of art, archaeology, and natural history. Population, in 1896, 38,518; in 1901, 39,886.

Poitiers was the capital of the Pietones or Pictavi, whence its modern name. The Romans called it Limonum. There are still a number of Gallic and Roman remains in the town and vicinity. Christianity was introduced in the third century and about 353 Saint Hilary became the first Bishop of Poitiers. In the fifth century the town fell into the hands of the Visigoths, whose King, Alaric II., was defeated by Clovis in battle near Poitiers in 507. In 732 Charles Martel checked the advance of the Saracens in the world-famous battle fought in the neighborhood. Near Poitiers, during the Hundred Years' War, the English, under Edward the Black Prince, gained a notable victory over the French under their King, John II., the Good, September 19, 1356. The French, whose forces outnumbered the English more than five to one, opened the battle with a furious charge, but were thrown back by a volley from the English archers, and totally routed by the onset of the English men-of-arms. The slaughter of French knights was large. King John was taken prisoner. See POITOU. Consult Ledain, *Histoire sommaire de la ville de Poitiers* (Fontenay-le-Comte, 1892).

POITOU, pwá'tōŏ'. A former province of Western France, now included within the departments of Vienne, Deux-Sèvres, and Vendée. The capital was Poitiers (q.v.). The ancient inhabitants of the region were the Pictavi or Pietones. It was overrun by the Franks in 507. Charles the Great placed Poitou under the jurisdiction of a count whose descendants, at the beginning of the tenth century, assumed the title of dukes of Aquitaine. It came into the possession of the English kings through the marriage of Eleanor of Aquitaine with Henry II. (q.v.), but was seized by the French King Philip Augustus in 1204. England held it again for about ten years after the Peace of Bretigny (1360), following the battle of Poitiers (1356). In 1416 it was permanently united with the French Crown.

POKANOKET. A North American Indian tribe. See WAMPANOAG.

POKE (*Phytolacca decandra*). A perennial herb of the natural order Phytolaccaceæ, native of North America, but distributed also in Northern Africa, the Azores, and the Hawaiian Islands

and China, and naturalized in Southern Europe. It is often called garget, pigeonberry, and seoke, and is found generally in good soil of waste

FLOWERING STEM AND FRUIT OF POKE.

places, as uncultivated fields, often attaining a height of more than six feet. See PHYTOLACCA, and Colored Plate of POISONOUS PLANTS.

POKER, or DRAW POKER. A game of cards said to be derived from primero or prime, a favorite English game of the sixteenth century. In France during the following century primero became ambigu, and a little later another variation, called brag, sprang up in the west of England, from which poker is more directly descended in its American form. The game may be played by from two to six persons. A full pack is used and five cards are dealt to each player, one at a time, after which, beginning at the dealer's left, each one may discard any or all of his cards, calling for as many new ones as he discards. This is the draw, and the player holding the most valuable hand is the winner. Beginning with the lowest, the values are as follows: a pair, two pairs, three of a kind (i.e., three cards of the same value), a straight, or five cards in regular order (in determining the value of 'straights,' the ace ranks either below the two or above the king, but stands at the end); a flush, i.e., where all five cards are of the same suit; a full house, full hand, or full, which consists of three of a kind, and a pair together; four of a kind; a straight flush, in which the cards are all of the same suit; and the royal flush, in which the cards of the same suit are the highest obtainable. Of the various methods of keeping score in the game of poker the following is the simplest: Before the play is opened counters are divided in equal value among the players. Before examining a hand each player deposits in the pool a value in counters previously agreed upon. This is the 'ante,' after which each player in succession after looking at his hand determines whether or not he will play. If he decides to

play he is required to put up double the 'ante' or as much more as he wishes up to the value of his hand and the limit agreed on before the game commences. The player at his left has also the choice of staying out or depositing in the pool the same number of chips as the player who preceded him, in which case he is said to 'see' him; or he may 'raise' or 'go him better,' in which case he deposits in the pool more than did his predecessor. The next or third player has also the choice of staying out or 'raising' the preceding player, and so on with each in turn, one or more times around. Should all the players except one fall out, the one who remains takes the pool without showing his hand. Again, all the players in the game may 'see' the one that 'raised' last, in which case they are said to 'call' the player's hand. Should none of the others have a better hand they let the one who has been called take the pool without displaying their own hands, otherwise the higher hands are tabled and the winner takes the pool. It is sometimes agreed that the players who desire cards in the beginning of the game must add to their 'antes,' and sometimes players make bets before they make their draw. The 'ante' is large or small, according as the 'eldest' hand plays; the common method being to require each player to 'ante' twice as much as the eldest hand, who will then have to make good at his next turn the rest of the 'ante,' or else fall out of the game. 'Bluffing' is where a player bets high on a weak hand in the hope that the other players, thinking his hand justifies the bet, will stay out of the game and thus leave the pool to the 'bluffer.' Apart from 'bluffing' the only part of poker in which skill is requisite is in discarding. Thus, when a player holds four of a suit he will often discard the fifth in the hope of securing a 'flush.' Some idea of the strength of a player's hand is got by taking note of the number of cards he calls for.

POKOMOS, pō-kō'mōz. A Bantu nation of the Tana basin, British East Africa, long oppressed by the Galla and the Swaheli. They are of medium height and of light brown color. Their huts are of beehive shape on raised platforms along the river banks. They are monogamists, and are truthful. The Pokomos, in common with many other tribes of this region, are at a low stage of culture, having a loose type of social organization, a well-developed totemic system, and a firm belief in magic.

POKOMOS. A Central American Indian tribe. See **MAYA**.

POL, pól, WINCENTY (1807-72). A Polish poet, born at Lublin. Educated in a Jesuit college at Tarnopol, he thence went to Lemberg, where he came in touch with French Romanticism. After traveling through Poland, in 1830 he became professor of German at Wilna, and in the same year, throwing in his lot with the liberators, wrote his first patriotic songs. Returning from exile in 1849, he was professor of geography at Cracow until 1853. He was forced to resign from this post, but returned to Cracow after several years in Lemberg. In his last years he was totally blind. Pol's most popular work was *Songs of Our Land* (1843), which deals with the various elements of the Polish population, while his best book is probably *Pictures from Life and Travel* (1847). His genius was essentially lyric and simple, at its best in descriptions of nature

or of homely life. His collected works appeared at Lemberg (1875-78).

POLA, pō'lá. The chief naval station of Austria-Hungary, with one of the finest harbors in Europe, in the Crownland of Istria, on the Adriatic Sea, about 53 miles south of Trieste (Map: Austria, C 4). The bay, which is thoroughly sheltered, is spacious enough to accommodate a very large fleet. The town is strongly fortified by walls and a citadel, overlooking the bay. The entrance to the bay is commanded by two forts and by various other fortifications on the islands in the bay and on its shores. Here are the dockyards, dry docks, and repair shops of the Austrian navy, the headquarters of the Admiralty, a hydrographic bureau, and various technical institutions. The town has several very imposing Roman remains, among which are the well-preserved temple of Augustus and Roma, the colossal Imperial amphitheatre, which could seat 25,000 persons, and the Porta Aurea, a sumptuous triumphal arch, dating from the beginning of the Christian Era. The Marine Casino and the Monte Zaro, with the fine statue to Admiral Tegetthoff, form a delightful pleasure resort. Pola is an important commercial port. It has grown from 1100 inhabitants in 1851 to 45,052 in 1900 (including 7657 on garrison duty). About 40 per cent. of the population are Italians, the rest being mainly Serbo-Croats and Germans.

Pola is of very ancient origin. It was destroyed by Julius Caesar, but rebuilt by Augustus at the request of his daughter Julia, from whom it obtained its name, Pietas Julia. It was a station of the naval fleet and bore the name of Republica Polensis. It was taken by the Venetians in the middle of the twelfth century, and was destroyed in the struggle between Venice and Genoa. Its present prosperity dates from about 1855.

POLAK. See **POLAND**, paragraph on *Ethnology*.

POLAND, pō'land. A former kingdom of Europe, whose territory is now included in Russia, Austria-Hungary, and Prussia. At its greatest extent, previous to 1660, it had an area of about 375,000 square miles, with a population of about 15,000,000, and extended northward to the Baltic Sea and the Gulf of Riga; westward to Brandenburg; southward to Hungary, Moldavia, and nearly to the Crimea; and eastward so as to include most of the basin of the Dnieper. About six-sevenths of this area is now included in the Russian Empire, embracing Russian Poland (see **POLAND, RUSSIAN**), West Russia (Lithuania, Volhynia, etc.), a great part of Little Russia, Livonia, and Courland. The part of Poland belonging to Austria constitutes the Crownland of Galicia (q.v.). The parts of the kingdom incorporated in Prussia include Posen (q.v.), West Prussia (q.v.), and the District of Ermland (q.v.), in East Prussia. Before the final partition in 1795 the area of Poland was reduced to 94,164 square miles, with a population of 4,500,000.

ETHNOLOGY. The territory comprised in the Kingdom of Poland before its dismemberment was inhabited by four ethnic types. Poles, Little Russians (Ruthenians), White Russians, and Lithuanians. The Poles proper have been identified with the Polianes, a branch of the Lekhs dwelling on the Vistula in the sixth century. The great

Slav movement from the second to the sixth century A.D. had dispersed the tribes in all directions, toward the Baltic, beyond the Elbe, and into the Danube basin and the Balkan peninsula. By the twelfth century the Germans had in a great measure pressed back the Western Slavs to the banks of the Vistula, and the development of Polish power was forced to the east and south among the Slav groups.

Ethnically the Poles belong to the Western Slav group. The bulk of them live in Russian Poland and adjoining parts of Russia, Western Galicia, and the Prussian provinces of Posen and Silesia. They are below medium stature, their average height being 1.624 meters, and are mainly brachycephalic and blond. Deniker classes them in his fair, sub-brachycephalic, short, or eastern race, and sees among them traces of a secondary or Vistulian race, fair, mesocephalic, and of very short stature. Race fusion has energetically acted in this region among various sections of the Slavs, so that the Poles have the qualities coming from a good race mixture. Other Slavic tribes, as the Polaks or Podlachians in the Russian Government of Grodno, on the Polish frontier, and the Polesians of Western Russia have considerable Polish mixture. In Prussia, by the higher birth-rate and by the absorption of German elements, the Poles have increased remarkably, weeding out colonies of Germans in Polish districts, and planting colonies in other portions of the kingdom, notably in West Prussia and Silesia. Under this impulse they have taken to commerce and education with new energy. In some districts they are expropriating the German landlords and sending Polish peasants to take their places. The other fragments of the Polish kingdom in Russia and Austria also show this movement, though not with the same degree of progress as in Prussia.

HISTORY. Polish historians profess to go as far back as the fourth century, but the list of rulers which they give are probably those of separate tribes, and not of the combined race now known as Poles. At any rate, the history of Poland previous to the middle of the ninth century is too legendary to have much value. About 840 a kingdom was organized out of kindred tribes under the Piast line of rulers, whose origin is uncertain. Ziemowit, said to be the second ruler of the Piast dynasty, is considered to be the first ruler whose history is to any extent to be relied upon; and it was not till a century after, when his descendant Meczyzlaw (Miecislav or Mscislaw) I. (962-92) occupied the throne, and became a convert to Christianity, that Poland really came into the field of European history. Mieczyslaw divided his dominions among his sons; but one of them, Boleslaw (or Boleslas) I. (992-1025), surnamed the Brave, soon reunited the separate portions, extended his kingdom beyond the Oder, the Carpathians, and the Dniester, and carried on a successful war with the Emperor Henry II. Under him Poland began to assume unity and consistency. About the same time the distinction between the nobles or warrior class and the agriculturists was distinctly drawn. This was of the utmost importance in the development of Poland, as it created a sharply defined caste, a military aristocracy entirely out of sympathy with the peasantry, which became ultimately one of the most arrogant and oppressive in Europe. An important event was the foundation of the

archiepiscopal see of Gnesen in 1000. Shortly before his death Boleslaw exchanged the title of Pinst for King. He was succeeded by his son Mieczyslaw II. (1025-34), during whose reign the Danes, the Hungarians, and the Russians made themselves masters of various territories which had been occupied by the Poles. Under Casimir I. (1034-58) and his warlike son, Boleslaw II., the Bold (1058-81), Poland regained something of its former power. The latter monarch having with his own hands murdered the Bishop of Cracow (1079), the country was laid under the Papal interdict and Boleslaw fled to Hungary, where he died. Boleslaw III. (1102-39), an energetic monarch, conquered Pomerania, defeated the pagan Prussians, and defended Silesia against the Emperor Henry V. A division of the kingdom among his sons was productive of much internal dissension. Silesia was severed from Poland, principalities ruled by branches of the Piast dynasty being established there. Ultimately, Casimir II. (1177-94) reunited the severed portions, with the exception of Silesia, and established on a firm footing the constitution of the country. A senate was formed from the bishops, palatines, and castellans, and the rights of the clergy and the peasantry were accurately defined.

Soon after Casimir's death Pomerania emancipated itself from Polish rule. In the thirteenth century the Teutonic Knights subdued the heathen Prussians and established their dominion on the shores of the Baltic, becoming formidable neighbors to the Poles. The Mongols swept over the Polish territories in 1240, and defeated the Poles, Silesians, and Teutonic Knights in the battle of the Wahlstatt (April 9, 1241). This terrible invasion was followed by a period of general decadence, and for a while the Polish realm as such almost ceased to exist. Poland was divided into a number of independent principalities and their dissensions led to the loss of large districts. During this period many parts of the country began to be colonized by Germans, who did much for Poland by establishing industries and developing municipal institutions. Large numbers of Jews, persecuted in Western Europe, took refuge about this time in Poland. The country recovered under Ladislaw (Wladislaw) I. (1306-33), surnamed *Lokietek* (the Short), who abolished judicial abuses and illegally acquired privileges, and assembled the first Diet for legislative purposes. He carried on successful campaigns against the Teutonic Knights, supported by the Grand Prince of Lithuania, and came to be known as the 'father of his country.' Under him Cracow became the permanent capital of Poland. His son, Casimir III., the Great (1333-70), increased the power and prosperity of Poland by cultivating the arts of peace, amending the laws, and consolidating his territories by profitable exchanges with the neighboring powers. The Principality of Halicz (Galicia) was annexed to Poland. Extensive privileges were conferred on the Jews at a time when the nations of Western Europe were visiting on them the rigor of persecution. The foundations of the University of Cracow were laid. In the latter part of his reign Casimir fought successfully against the Tatars and Lithuanians. With Casimir the Piast dynasty became extinct. His nephew, Louis the Great, King of Hungary, succeeded him by the will of the deceased monarch and the election of

the Diet; but during his reign Poland was treated merely as an appanage of Hungary. After the death of Louis of Hungary without male issue (1382) Hedwig, daughter of Casimir the Great, was chosen Queen of Poland in 1384 by the Diet, and two years later she married Jagello (Jagellon), Grand Prince of Lithuania, who ascended the throne as Ladislas II. (q.v.), and founded the Jagellon dynasty, which ruled over Poland and Lithuania from 1386 to 1572, and under which Poland was at the height of its greatness. Jagello, at his accession, embraced Christianity, which was now introduced into Lithuania, hitherto a heathen country. Jagello inflicted a great defeat upon the Teutonic Knights at Tannenberg in 1410. He was succeeded in Poland by his elder son, Ladislas III. (1434-44), and in Lithuania by his younger son, Casimir. Ladislas, whom the Hungarians placed upon their throne, was overwhelmed by the Turks and slain in the battle of Varna. He was succeeded after an interregnum by his brother, Casimir IV. (1447-92), during whose reign the Teutonic Knights, by the Treaty of Thorn (1466), ceded West Prussia to Poland, and agreed to hold East Prussia as a Polish fief. Casimir rewarded the inferior nobles, or warrior class, with more extensive privileges, putting them on an equality of rank with the great chiefs of the realm, and at the same time necessarily oppressing the peasantry. Manufactures and commerce revived to a remarkable extent in the western provinces. The brief reigns of his two elder sons, John I. (1492-1501) and Alexander (1501-06), were marked only by the increased power of the Diet, which was steadily absorbing the real authority, and converting Poland from a monarchy to an oligarchy.

Sigismund I., surnamed the Great (1506-48), the youngest son of Casimir IV., raised the country to the utmost pitch of prosperity. Generous and enlightened, he was beloved by the masses, while his firmness and justice commanded the respect of the turbulent nobles. In a war with Russia, however, in the early part of his reign, he lost Smolensk. His son Sigismund II., Augustus (1548-72), was a worthy successor to his father. During his reign the extraordinary privileges of the higher nobles were curtailed or abolished. Lithuania was finally joined indissolubly to Poland, the union being proclaimed by a Diet held at Lublin in 1549. There was but one Diet for the united realm, which was to be converted into an elective monarchy on the death of the reigning King, who had no heirs. Lithuania retained, however, her own army, treasury, and laws. Lithuania was at the same time reduced in area by the annexation of Podlachia, Volhynia, and the Ukraine to Poland. Livonia was ceded to Poland by the Knights Sword-bearers and successful wars were waged against the Russians and the Turks. The Polish realm then stretched across Central Europe from the Baltic Sea to the Dniester, with its western boundary less than 90 miles from Berlin, and its eastern frontier about 150 miles from Moscow, covering an area of more than 370,000 square miles. The population almost doubled under the two Sigismunds. The Reformation spread rapidly in Poland, but its progress was arrested by the Jesuits, who persuaded the nobles that their interests lay in the preservation of the Catholic hierarchy. With the death of Sigismund Augustus in 1572 the Jagellon dynasty became extinct and Poland

passed under the régime of elected kings. The election was by the two chambers of the Diet, the Senate or Chamber of the Chief Nobles, and the Chamber of Nuncios, or Representatives of the Inferior Nobles. The Diet sat only six weeks, and its decisions were required to be unanimous; so that if the *liberum veto* (the right of forbidding the passing of any measure) were freely exercised even by a single member, all legislation was at a standstill. More unnatural still was the recognized right of any number of nobles to confederate for the purpose of effecting their will by force of arms.

This singular constitution produced the most inefficient government that was ever established in a great State. Political factions could hamper all action in great national crises, and the so-called republic became a most pernicious oligarchy. In the *liberum veto* might easily be found the seed which produced the final disintegration. The first elective monarch was Henry of Valois, Duke of Anjou (1573-74), who had barely assumed the crown when he laid it down to become King of France as Henry III., and was succeeded by Stephen Báthory (1575-86), Voivode of Transylvania. Stephen's successor, Sigismund III., Vasa (1587-1632), was the son of John III. of Sweden by a daughter of Sigismund I. His claims to the crown of Sweden, which he wore for a time, brought on wars with that kingdom. Gustavus Adolphus carried on victorious campaigns against the Poles in 1621-29 and conquered Livonia. After Sigismund III., under whom Warsaw supplanted Cracow as the Polish capital, came his two sons, Ladislas IV. (1632-48) and John Casimir (1648-68). The imprudent attempts of the sovereigns of the House of Vasa to amend the Constitution only excited the suspicion of the nobles, and led to a further curtailment of royal authority. In 1648 the Cossacks, goaded by oppression, rose in rebellion under Bogdan Chmielnicki (q.v.), put themselves under the protection of Russia (1654), and ever afterwards proved themselves the most inveterate enemies of the Poles. In 1655 Charles X. of Sweden invaded Poland while the Poles were engaged in war with Russia, and in 1656 he was joined by Frederick William, the Great Elector of Brandenburg. The Poles at first fought victoriously under Czarnecki, but in July, 1656, they were vanquished in a great battle at Warsaw. In 1657 Brandenburg went over to the side of Poland, which then renounced its suzerainty over the Duchy of Prussia (East Prussia). In the Peace of Oliva, in 1660, Poland formally ceded Livonia to Russia, and the Ukraine beyond the Dnieper was given up to Russia in the Treaty of Andrussovo, in 1667. Michael Wisniowiecki (1669-73), the son of one of the ablest Polish leaders, but himself an imbecile, was elected as successor to John Casimir, who had abdicated the throne. A war with Turkey, concluded, in spite of the victories of John Sobieski, by an ignominious peace, was the chief event of his reign. In 1674 the crown was conferred on John Sobieski, who shed lustre on the Polish arms by overthrowing, in conjunction with the German princes, a vast Turkish army in front of Vienna in 1683, and saving the Hapsburg capital. His reign, however, was productive of little good to the internal administration. He died in 1696 and the French Prince de Conti was elected and proclaimed King. Lack-

ing efficient support from France, Conti renounced the office; and Frederick Augustus I. of Saxony, surnamed the Strong, a protégé of the House of Austria, entered Poland at the head of a Saxon army, and was chosen King as Augustus II. (1697-1733). Augustus never identified his interests with those of his Polish subjects. The Treaty of Karlowitz, in 1699, brought the last struggle between Poland and Turkey to a close and restored to Poland a large part of the Ukraine. In 1700 Augustus entered into an alliance with Russia and Denmark for a joint attack upon Sweden, then under the rule of Charles XII. This conflict brought nothing but misfortune. The war with Sweden was unpopular in Poland; in fact, the Poles of the eastern provinces received Charles with open arms; but his attempt to force upon them Stanislas Leszczyński as their King deeply wounded their national pride. At Altranstädt in 1706 Augustus was compelled to abdicate, but after the defeat of Charles XII. by Peter the Great at Poltava, in 1709, he returned, supported by Russia, and Russian as well as Saxon troops were maintained in the country in spite of the protest of the people.

This beginning of Russian interference was a visible mark of the decline of Poland. The Polish army was reduced at the instance of Peter the Great, and the evil example of the Saxon Court brought in immorality, prodigality, and effeminacy. Protestants were persecuted and excluded from public office. The election of Augustus III. (1733-63) was accomplished by the most shameless bribery and under the compulsion of Russian troops, and led to the War of the Polish Succession. (See SUCCESSION WARS.) His reign was of the same character as that of his predecessor. Toward its close the more enlightened of the Poles entered into a league to promote the establishment of a well-organized hereditary monarchy. But the conservative or republican party was equally strong, and relied on Russian influence, which was used to continue the divisions in the country. Catharine II. of Russia determined at the beginning of her reign to control Poland or take it, as it barred the way to the accomplishment of her great ambition, to bring Russia fully into the circle of the Western powers. On the death of Augustus III. she, acting in harmony with Frederick of Prussia, put forward as a candidate for the Polish throne Stanislas (Augustus) Poniatowski, an old lover of her own. This roused the national spirit of the Poles to intense opposition. The monarchic party, led by Prince Czartoryski, had succeeded in abolishing the *liberum veto* and in otherwise strengthening the Government. Catharine, in alliance with Prussia, seized the pretext furnished by the oppression of religious dissidents of the Protestant and Greek communions by this dominant party, and appeared as the champion of religious liberty. Russian troops entered the country and forced the election of Poniatowski (1764). The Confederation of Bar (so called from Bar in Podolia) was formed in 1768 by a few zealous patriots, and entered upon a vigorous resistance to Russia. Similar confederations were organized, and Turkey seized the occasion to attack Russia. To avoid the danger of a general war and to obtain compensation for the inevitable seizure of Polish territory by Russia, the governments of Prussia and Austria proposed a treaty of parti-

tion, which was concluded at Saint Petersburg, August 5, 1772. Russia acquired a part of the old Lithuania, comprising an area of 42,000 square miles, with a population of 1,800,000; Prussia took West Prussia without Danzig and Thorn, and the district on the Netze, 13,000 square miles, with 415,000 inhabitants; and Austria received Galicia and Lodomeria, 27,000 square miles, with 2,700,000 inhabitants.

Members of the Polish Diet were freely bribed to consent to the cessions. The old anarchical Constitution with the *liberum veto* was restored. The country was now aroused to a sense of its danger; and the result was the adoption of the admirable Constitution of 1791, which gave political rights to the cities, civil rights to the peasantry, and rendered the kingly authority hereditary. Frederick William of Prussia promised the Polish patriots support against Russia. Catharine II., however, by intrigues and bribery, won a small number of the higher Polish nobility, who formed the Confederacy of Targowitza (May, 1792), and protested against the new Constitution as derogatory to the ancient liberties. Catharine, thus armed with a pretext for interference, invaded Poland with an overwhelming army. The Poles fought bravely under Kosciuszko (q.v.) and won a victory over the Russians at Dubienka (July 17, 1792); but King Stanislas, after pledging his loyal support to the nation, gave his adhesion to the Confederacy of Targowitza. A Prussian army now entered Poland, and the country, its strength broken, was subjected to a second partition (July 17, 1793). Russia took a large part of Lithuania, half of Volhynia, Podolia, and the portion of the Ukraine which had remained with Poland—96,000 square miles, with about 3,000,000 inhabitants. Prussia appropriated the westernmost part of the kingdom, 22,000 square miles, with 1,100,000 inhabitants. A Diet convened at Grodno was compelled to sanction this 'cession.' A general rising of the Polish people to resist this dismemberment of their country took place in 1794. Kosciuszko was made dictator and drove the Russians from Warsaw, but dissension among the Poles ruined their cause at the moment of seeming triumph. The Russians and Prussians reentered the country with increased numbers, and on October 10, 1794, Kosciuszko was decisively defeated and taken prisoner at Maciejowice by the Russians. On November 8th Suvaroff entered Warsaw, and Polish resistance came to an end. The third and last partition (October 24, 1795) distributed the remainder of the country. Russia taking 45,000 square miles, with 1,200,000 inhabitants; Prussia, 21,000 square miles (including the capital, Warsaw), with 1,000,000 inhabitants; and Austria, 18,000 square miles, with 1,000,000 inhabitants. King Stanislas resigned his crown and died at Grodno as a pensioner of Russia in 1798. Napoleon, who promised the restoration of Poland and thereby gained the support of the patriots, was hailed with satisfaction, but all that Napoleon accomplished was the establishment, by the Treaty of Tilsit (1807), of the Duchy of Warsaw, formed out of the Polish territories taken by Prussia in 1793 and 1795. This State received a fairly liberal constitution, and King Frederick Augustus of Saxony as its nominal head, the real power being exercised by the French Emperor. The duchy was increased by Western Galicia, ceded by Austria in the Treaty of Schönbrunn, in 1809. The Poles

furnished a considerable contingent to the French armies. The disaster to the French in Russia in 1812 and the advance of the allied army in 1813 put an end to the existence of the duchy. The partition of Poland was rearranged by the Congress of Vienna in 1815. Prussia retained West Prussia and recovered the western portion of the territory embraced in the Duchy of Warsaw, which region was constituted into the Grand Duchy of Posen; Austria recovered the territory which she had taken in the first partition of Poland in 1772 (Galicia); Russia was secured in the possession of all the territories that she had appropriated in the three partitions; out of the bulk of the Duchy of Warsaw was created a new Kingdom of Poland, which was to be united with the Russian Empire by a personal union. The city of Cracow, with a small surrounding territory, was erected into a republic, which was placed under the protection of the Great Powers. This final partition of Poland gave Russia 220,500 square miles, Prussia 26,000 square miles, Austria 35,500 square miles. Of the portion which was to belong to the Emperor of Russia, about 49,000 square miles were included in the new Kingdom of Poland.

Alexander I. of Russia first granted a liberal constitution, a separate standing army, and liberty of the press. This, however, did not prevent the Polish nobles from conspiring for the restoration of the liberties of their country. Secret societies, as elsewhere in Europe, fomented the revolt, and a general insurrection of the people, headed by the aristocracy, took place. On November 29, 1830, a military insurrection broke out at Warsaw, and in a short time the Russians were driven from the country. The leadership of the movement was assumed by a number of nobles, most prominent of whom was Prince Adam Czartoryski (q.v.). Chlopicki (q.v.) was appointed dictator. In January, 1831, the independence of Poland was proclaimed, and Czartoryski was made head of the national Government, Chlopicki having laid down his dictatorship. A Russian army under Diebitsch invaded the country. The Poles fought with their wonted bravery and for months kept the enemy at bay, but their main army, under Skrzynecki, was defeated at Ostrolenka on May 26th. Paskevitch, who succeeded to the command of the Russian forces on the death of Diebitsch, carried on the war with vigor, and was aided by the inveterate dissensions among the Poles. Warsaw was taken on September 8th, and the Polish armies sought refuge on Prussian and Austrian soil. Dilatoriness on the part of the military leaders and the delay occasioned by fruitless negotiations with Emperor Nicholas had proved fatal errors.

There followed for those who had participated in the rebellion imprisonment, banishment, confiscation, and enforced service in the Russian army. From this time all self-government in Poland was suppressed. The liberal Constitution of 1815 and laws were abrogated; strict censorship of the press and the Russian spy police system were established in all their vigor; the country was robbed of its rich literary collections and works of art; and the most severe and arbitrary measures were taken to Russianize the people. Large numbers of Poles were forced to take refuge in France and elsewhere, where they carried on an active revolutionary propaganda, and some of them played an important part in

the struggle for liberty in other countries. (See BEM; DEMBINSKI. The year 1846 witnessed another effort on the part of the Poles to shake off the yoke that had been imposed upon them. The movement did not proceed far. In Prussian Poland (Posen) it was promptly checked by the arrest of Mieroslawski (q.v.) and other leaders, while in Galicia the peasantry (in great part Ruthenians) rose against the nobles, the leaders in the outbreak, and massacred many of them. In the same year the Republic of Cracow was incorporated with Austria. In 1848 there was an insurrection in Posen, which was quickly suppressed. After the accession of Alexander II., of Russia, in 1855, the condition of the Poles was considerably ameliorated, and an act of amnesty brought back many of the expatriated Poles.

The Czar evinced by his acts his readiness to make far-reaching concessions to his Polish subjects, but in spite of this there were violent revolutionary demonstrations in 1861, which were repressed with bloodshed. In 1862 a régime of partial autonomy was inaugurated under the guidance of Marquis Wielopolski, a member of the Polish aristocracy; but the Russian Government was not trusted by the Poles, and a revolutionary fever had taken hold of the youth, which found vent in fresh outbreaks and in attempts to assassinate the Viceroy Constantine (brother of the Czar) and Wielopolski himself. The Russian Government proceeded to stern repressive measures, and in January, 1863, resorted to a barbarous expedient in order to quell the revolutionary spirit—a wholesale conscription, suddenly executed, which should at one stroke remove the patriotic young men from the field of their activity. This measure, which could be but partially carried out, brought matters to a crisis and the country rose in insurrection. This movement differed from the preceding uprisings in that it was largely a democratic agitation and was carried on under the guidance of a secret revolutionary committee. This body issued its first proclamation in February, 1863, and a week afterwards Mieroslawski raised the standard of insurrection on the Posen frontier. The principal commander of the patriots was Langiewicz. It was little more than a mere guerrilla war, and no great or decisive conflicts took place. The sympathy of Europe was largely enlisted on behalf of the Poles, but the remonstrances of the Powers were wholly disregarded by the Czar's Ministers. The Poles fought heroically against desperate odds. The national committee continued to guide the revolt and resorted to terrorism, even assassination, to carry out its measures and enforce obedience. The overwhelming numbers of the Russians soon carried everything before them, and early in 1864 the last sparks of the insurrection were stamped out. Large numbers of the patriots were executed and crowds were transported to Siberia. Lithuania and other parts of old Poland, not included in the so-called kingdom, were at once subjected to a process of Russification, which was carried out with extraordinary barbarity. By an Imperial ukase of February 23, 1868, the government of Poland was completely incorporated with that of Russia. Russian has been made the language of the administration and of the schools. To the Polish peasantry Russian government brought a boon in the shape of emancipation (1864). The Pan-slavists of Russia (see PANSLAVISM) regard agitation

for Polish nationality as treason to the greater cause of Slavic union. In spite of the measures directed against it, the Poles of Russia cling firmly to their nationality, and their authors and journalists keep alive their attachment to their native tongue. Galicia, where constitutional government exists under Austrian rule, is a great stronghold of Polish nationality, Craeow holding a place next to Warsaw as an intellectual focus of the people.

In Prussian Poland the struggle between Pole and German has been very active and has been fought out on an economic basis. It was Bismarck's policy to plant a Germanic population on Polish soil, and to this end vast sums were spent in buying up Polish estates, which were then peopled with German colonists. In spite of the strenuous efforts of the Government, however, the Poles have more than held their own. The national spirit has undergone a great revival and has united the nobility and the masses in opposition to the domination of the Prussians. The policy of Prussification has been pursued by the Government through the introduction of the German language in the schools, a measure which led to bitter dissatisfaction among the Poles and some slight disturbances in 1901.

BIBLIOGRAPHY. Of works in English, Dunham, *The History of Poland* (London, 1834), is compact and useful, especially in its earlier portions; Fletcher, *The History of Poland from the Earliest Period to the Present Time* (ib., 1831), is an interesting work, but less reliable than the preceding. Consult also: Wolski, *Poland* (London, 1883); Moltke, *Poland* (ib., 1885), translated from the German, a valuable sketch; Morfill, *The Story of Poland* (New York, 1893), in the Story of the Nations series. Lelewel, *Histoire de Pologne* (Paris, 1844), is a Polish plea, but standard. Salvandy, *Histoire de Pologne* (ib., 1855), is standard for Polish history up to the reign of John Sobieski; Röpell and Caro, *Geschichte Polens* (Hamburg, 1840-63), is the fullest and best of general histories of Poland. On special periods there are Brüggens, *Polens Auflösung; kulturgeschichtliche Skizzen aus den letzten Jahrhunderten der polnischen Selbstständigkeit* (Leipzig, 1878); Röpell, *Polen um die Mitte des 18. Jahrhunderts* (Gotha, 1876), an able treatise on the period 1697-1763; Rultrière, *Histoire de l'anarchie de Pologne* (Paris, 1807, 1819). On the revolutionary movements in Poland, see Rultrière, *Révolutions de Pologne* (Paris, 1862); Kunz, *Der polnisch-russische Krieg von 1831* (Berlin, 1890); Kozmian, *Das Jahr 1863* (Vienna, 1896). On the partitions, Ferrand, *Les trois démembrements de la Pologne* (Paris, 1864); Beer, *Die erste Teilung Polens* (Vienna, 1873); Bain, "The Second Partition of Poland," in the *English Historical Review* for April, 1891.

POLAND, RUSSIAN. An historical division of Russia, forming the westernmost part of the Russian Empire. It is bounded on the north by Prussia and the Russian Government of Kovno, on the east by the governments of Vilna, Grodno, and Volhynia, on the south by the Austrian crownlands of Galicia and Silesia, and on the west by Prussia, Silesia, and Posen. Poland is known officially as the *Privislinskira Gubernii*, or Governments on the Vistula, and consists of ten governments, Kalisz, Kielce, Lomza, Lublin,

Piotrkow, Plock, Radom, Siedlce, Suvalky, and Warsaw, with a total area of 49,159 square miles. The greater part of the country is a plain, rising in the south into spurs and foothills of the Carpathian Mountains. The chief river is the Vistula, which passes from south to northwest through the centre of the country, and with its branches waters the greater part of it, though the western part is drained by the German river Warta. The soil is fertile and one-half of the area of the country is arable land, while one-third is covered with forest. The principal crops are potatoes, rye, oats, and wheat. The raising of live stock, especially sheep and horses, is also important. Mining is carried on to a considerable extent in the southern highlands, and large quantities of coal and iron ore are produced. The total value of manufactured products amounts to \$125,000,000 annually. Commerce is facilitated by navigable rivers and over 1500 miles of railroad; the exports pass chiefly by way of Danzig, and consist principally of wheat, timber, wool, and cattle products. Although absolutely incorporated with Russia, Poland forms a separate general government, with a Governor-General residing in Warsaw. The total population in 1897 was 9,455,943, consisting chiefly of Poles, with about 1,000,000 Russians, 1,500,000 Jews, and a number of Germans. Russian is the official language and the language prescribed in the public schools. The Roman Catholic Church is adhered to by four-fifths of the inhabitants, and is officially administered by the Ministry of the Interior at Saint Petersburg. For further details, see articles on the separate governments; and for history, see **POLAND**.

POLAND, JOHN SCROGGS (1836-98). An American soldier, born in Princeton, Ind. He graduated at West Point in 1861, and was assigned as second lieutenant to the Second Infantry. In the Civil War he served in the Army of the Potomac until July, 1863, and was commissary of musters for the Department of Washington from September, 1863, to March, 1865. In June, 1862, he was promoted to be captain; in December, 1862, was brevetted major for gallantry at Antietam, Shephardstown, and Fredericksburg; and in May, 1863, was brevetted lieutenant-colonel for gallantry at Chancellorsville. In the battle of Gettysburg he was an aide on the staff of General Sickles. After the war he was an assistant professor at the Military Academy, first of drawing, then of geography, history, and ethics, and then again of drawing, until 1869; served on frontier duty for several years; and from 1881 to 1886 was head of the department of law at the United States Infantry and Cavalry School, Leavenworth, Kan. On the outbreak of the Spanish-American War in 1898 he was promoted to be brigadier-general of volunteers. He commanded for a time the Second Division of the First Army Corps at Chickamauga Park, Ga., and died of typhoid fever contracted there. He published a *Digest of the Military Laws of the United States from 1861 to 1868* (1868), *The Conventions of Geneva of 1864 and 1868*, and *Saint Petersburg International Commission* (1886).

POLAND-CHINA. A breed of hogs. See Hog, and Plate of Hogs.

POLANGUI, pò-lán'gè. A town of Southern Luzon, Philippines, in the Province of Albay

(May: Philippine Islands, H 6). It lies 20 miles northwest of Albany on the main road of the province, and on the Inaya River, in a situation very favorable for hemp traffic. Population, 10,050.

POLAR. See POLE AND POLAR.

POLAR BEAR. The white or ice bear of boreal regions. See BEAR.

POLAR CIRCLE, or ARCTIC CIRCLE. See ARCTIC.

POLAR CLOCK (from Neo-Lat. *polaris*, relating to the pole, from Lat. *polus*, from Gk. *πόλος*, *polos*, pivot, axis, pole, from *πέλωσθαι*, *pelesthai*, to be in motion; connected with Skt. *car*, to move). A form of polariscope invented by Sir Charles Wheatstone for telling the time of day, and based on the fact that light from the sun when scattered by the fine particles of the atmosphere becomes polarized. (See POLARIZATION OF SKYLIGHT.) This can be shown by looking at the sky through a plate of quartz or selenite and a Nicol prism, a series of colors being seen on revolving the Nicol. The effect is strongest if the apparatus is pointed toward the north pole of the heaven, and the succession of colors will follow from the motion of the sun, if the Nicol is allowed to remain stationary. In this way we can tell its position, and consequently the hour of the day, by the change in color. The polar clock, as described by Wheatstone, consists of a hollow conical tube so mounted that its axis can be brought parallel to the axis of the earth. At the base of the cone there is a glass disk, in the lower half of which there is a graduated semicircle divided into twelve parts representing the hours from six in the morning to six at night. This glass is fixed, but the conical tube itself can be rotated and contains at its larger end, adjacent to the glass disk just described, a second glass disk, on which at the centre are cemented a series of thin scales of selenite in the form of a star. These plates when viewed by polarized light exhibit strong contrasts of color. There is also on the glass an index, which is a prolongation of one of the principal sections of the selenite scales or plates. At the smaller end of the tube is mounted the Nicol prism with either of its diagonals making an angle of 45° with the principal section of the selenite plates. When seen through the Nicol the selenite will show a variety of rich colors, depending upon the position of the prism, but there will be two positions where the color will entirely disappear. At one of these positions a small disk of selenite will appear red, and at the other it will have the complementary color green, this effect being produced by placing the principal section of the small central disk $22\frac{1}{2}^\circ$ from that of the other sections of selenite forming the star. The time is ascertained by turning the tube on its axis until the color of the star entirely disappears, while the central disk remains red; the index should then point to the hour. Unlike the sun-dial, the polar clock need not be placed in the sun's rays; it may stand in the shade of a tree or building or at a window, and it may be used when the sky is overcast, unless the obscurity is too great. POLARISCOPE (from Neo-Lat. *polaris*, relating to the pole + Gk. *σκοπεῖν*, *skopein*, to view). An instrument which consists of any combination of a means of producing polarized light, or 'polarizer,' and a device for testing the polarization of light, or 'analyzer.' In ordinary light (see LIGHT) the direction of vibration is changing millions of times per second. As a result of reflection, or refraction, the direction may be made to remain constant, and the light is then said to be 'polarized' plane, elliptically, or circularly, according as the motion of the ether particle is linear, elliptical, or circular.

When light is reflected from the surface of a transparent medium, as glass, at the 'polarizing angle,' the tangent of which is equal to the index of refraction of the medium, it is found to be plane polarized, and the plane in which the incident and reflected rays lie is called the plane of polarization. If such a polarized beam of light is allowed to fall upon a second similar mirror at the polarizing angle, it will enter the medium or be reflected according as the plane of this reflection is parallel or perpendicular to that of the first reflection. Polarization by reflection was discovered by Malus in 1810. As early as 1690 Huygens discovered that the two rays of light produced by the double refraction in calcite were polarized at right angles to each other.

FIG. 1. TOURMALINE TONGS.

This apparatus consists of two plates of tourmaline so mounted as to revolve in their holders. The crystal or thin plate to be examined is placed between the two plates of tourmaline; the two plates act as polarizer and analyzer respectively.

Three methods of obtaining a beam of plane polarized light for experimental purposes are in general use, and are employed in polariscopes: (1) Reflection at the polarizing angle; (2) double refraction and the elimination of one of the beams, (a) by reflection (Nicol prism), (b) by sending it off to one side (Rochon prism, etc.); and (3) double refraction and the absorption of one beam, tourmaline plates. The Nicol prism (q.v.) is most generally employed in polariscopes and forms one of the best means for the production and detection of polarized light.

In a polariscope the polarizer and analyzer may be similar, or not. In the form devised by Norrenberg (Fig. 2) the polarizer is the mirror at the bottom of the apparatus, and the analyzer is a Nicol prism in the eye-piece at the top, or it may be that a bundle of thin plates of glass are used, as shown in the figure. When the plane of polarization of both polarizer and analyzer is the same, the ray which emerges from the polarizer will pass on through the analyzer, and they are said to be 'parallel' (Fig. 3); but if the two planes are perpendicular, then the beam

will all enter as the ordinary in the analyzer and be reflected and lost, and they are said to be 'crossed' (Fig. 4): the eye looking in at the eye-piece sees a dark field. If a plate of transparent

FIG. 2. NORREMBERG POLARISCOPE.

The polarizing mirror is shown in place, while above attached to the uprights are lenses for producing parallel, divergent, or convergent beams of light, and a support on which thin plates or other objects to be studied may be placed. The bundle of thin plates at the top used as an analyzer may be replaced by a Nicol prism, shown to the right at the base of the instrument, or by a mirror at the polarizing angle, shown to the left.

material be introduced between the polarizer and analyzer, it may happen that the field of the crossed combination will become light or colored. This will mean that the material has in some way affected the ray emerging from the polarizer so that it is no longer entirely cut off by the analyzer. Such substances are in general said

FIG. 3. POLARISCOPE WITH POLARIZING PRISMS PARALLEL.

FIG. 4. POLARISCOPE WITH POLARIZING PRISMS "CROSSED."

to be 'double-refracting.' Substances which do not so affect the polarized beam are called 'isotropic' or 'single-refracting.' The double-refracting substances are generally crystalline and fall into two broad classes, uniaxial and biaxial. In certain double-refracting crystals there is one direction in which all light travels with the same velocity, and hence no double refraction occurs. This direction is called the optic axis and such substances are uniaxial. In biaxial crystals there are two directions, or optic axes,

along which all light travels with the same velocity, and around which the optical properties group themselves. Substances are studied in the polariscope in either parallel or convergent (or divergent) light, and the double-refracting media in general produce two beams from the original beam coming from the polarizer, and these two new beams, traveling with different velocities, are made to interfere when their components are brought into the plane of the analyzer. As white light is generally employed at the polarizer, and as the kind of interference is a function of the wave length, colors are usually seen at the analyzer. A complete study of these color phenomena, and their general behavior in the polariscope, make it possible to determine the identity of most minerals from their optical properties. This branch of optics has developed into microscopic petrography, which has so supplemented the other tools of the mineralogist and geologist that these sciences have been revolutionized.

Certain substances, as quartz parallel to the optic axis, solutions of sugar, tartaric acid, etc., possess the peculiar property of rotating the plane of polarization to an extent depending upon the wave length of the light and the thickness of the layer traversed. That is to say, if the polariscope is set 'crossed' and a plate of quartz cut perpendicular to the axis introduced, the eye-piece field will appear lighter if monochromatic light is used, and it will be necessary to rotate the analyzer in order to again obtain the dark field. This rotation may be clockwise as viewed from the polarizer, 'right rotating' or 'dextro-rotary,' or it may be the reverse, 'left rotating' or 'levulo-rotary.' If white light is used, colors will appear in the field of view, and the tint 'crossed' will always be complementary to that seen in the 'parallel' position. These colors are in general due to the fact that, as the rotation for different colors is different, certain ones will be passed through the analyzer and others cut off.

The rotation of the plane of polarization in solutions of cane sugar is made use of commercially on a very large scale in testing raw sugar for its content of crystallizable sugar. Very many forms of apparatus have been devised for this especial purpose. One of the more complicated, due to Soleil, is shown in Fig. 5; D is the tube in which the sugar solution is placed; C is a double quartz plate, half right and half left rotating, which affords a very sensitive means of setting the instrument to the same adjustment each time; B is the polarizer; A is a combination of a Nicol prism and a quartz plate, which by rotation enables the observer to correct for the color of the solution and obtain the most sensitive tint in the double quartz plate, C; F is the analyzer; G is a small Galilean telescope focused upon C; and E is the compensating system which corrects the rotation due to the solution instead of following it up. A plate of right quartz, *b*, is just neutralized by wedges of left quartz, *a*, when they are as shown at *a*. If the solution rotates right, then the wedges are slid together so as to offer an excess of left rotation over *b* and neutralize the right rotation of the solution. If the solution is left rotating, the wedges are slid apart and the excess of right rotation of *b* neutralizes the rotation of the solution. The motion of the wedges is controlled by a rack and pinion, and

is measured by a scale which may be made to read off percentage of sugar directly, provided a solution of certain standard strength and length is used. In 1845 Faraday demonstrated that a piece of glass in a strong magnetic field would rotate the plane of polarization in the direction in which the current of the electromagnet flows,

no polarization in fog, cloud, or dense haze. As there is an evident connection between the polarization of skylight and the quantity of moisture, haze, or smoke in the atmosphere, there have been numerous investigations of this subject both from an observational and a theoretical point of view.

FIG. 5. POLARISCOPE FOR LIQUIDS.

and to an extent dependent upon the glass and the strength of the magnetic field. It has now been proved by Perkin and others that this is a rather common property of transparent media.

POLARIZATION. A term used in physics with many applications, but generally to signify a property of matter or of the ether which has a definite direction. A magnet is said to be polarized; so is a dielectric under the action of electrically charged bodies. When, owing to the passage of an electric current through an electrolyte, there are chemical actions at the electrodes which oppose the current, the electrolytic cell is said to be polarized. When a definite characteristic is given ether-waves—e.g. if the vibrations are all in one plane, or if they are all in circles or ellipses—they are called polarized. See ELECTRICITY; LIGHT; VOLTAIC CELL OR BATTERY; POLARISCOPE.

POLARIZATION OF SKYLIGHT. The polarization of blue skylight was known to Huygens, and is evident to any one who will look at the sky through a prism of Iceland spar. After a systematic investigation of the distribution of polarized light in different parts of the sky, Arago (1811) discovered that a certain portion or spot in the sky shows no polarization. This point varies with the altitude of the sun. Subsequently similar points were discovered by Arago (1840) and Brewster (1842). The maximum polarization occurs in a narrow zone 90 degrees distant from the sun. Similar but feeble polarization occurs in moonlit skies. There is

water surfaces was impossible. Observations of skylight during recent total eclipses of the sun seem to have shown that the amount of polarized light increases during and just before and after totality. Such an effect might be produced either by the increased condensation of aqueous vapor, owing to the cooling of the atmosphere within the shadow of the moon, or by the fact that in place of the ordinary sunlight we now have to do with the polarized light from the solar corona.

The most acceptable theory as to the origin of the polarization is that started by the experiments of Tyndall on the reflection of sunlight from delicate clouds of vapor and perfected by Lord Rayleigh, who showed that when light is transmitted through a cloud of particles smaller than the wave length of the light, the latter is scattered laterally and polarized in the plane of scattering. In 1899 Rayleigh submitted the additional demonstration that not merely the grosser particles of dust and aqueous vapor, but even the molecules of oxygen and nitrogen, and probably those of other gases, take part in the process of scattering and polarization. Consult *United States Monthly Weather Review* (Washington) for September, 1900, where will be found a summary of recent work in this field and a bibliography.

POLAR RESEARCH. The polar regions comprise all lands and seas within the polar circles, extending northward from the Arctic Circle and southward from the Antarctic Circle to the respective poles of the earth. The barrenness of the land, often ice-covered and largely devoid of animal and vegetable life, with the extended and heavy ice-fields in the sea, has made exploration slow and hazardous.

MOTIVES OF POLAR RESEARCH. Exploration in the far north has been more extensive than that in the far south, chiefly because the Arctic is much nearer to the great maritime nations

The simplest and most accurate polarimeter for studying this phenomenon was devised in 1872 by Prof. E. C. Pickering, director of the Harvard College Observatory. Observations made with this apparatus seem to show that the reflection of the sunlight from the surface of the sea into the atmosphere produced a decidedly perceptible disturbance of the polarization of skylight as compared with that observed from interior stations where such reflection from

and its waters merge with those which in modern times have been the predominant highways of sea trade. The whale and seal fisheries of the north opened the great era of Arctic discovery in the seventeenth century. For 150 years after Henry Hudson in 1607 examined the long edge of the pack-ice from Greenland to Nova Zembla, the annals of the Dutch and English whaling trade provided nearly all information of the Arctic area.

The commercial instinct that led to the first great Arctic voyages had two distinct phases. One was the endeavor to extend the limits of the northern fisheries; and while the prosecution of the Arctic whaling industry added a vast sum to the wealth of the world—estimated at over \$600,000,000 in 200 years before the middle of the nineteenth century—it naturally resulted in largely extending our knowledge of the north polar world. The other phase was the desire to shorten the water route between the ports of West Europe and the rich Orient by finding either a northwest or a northeast passage between them. This ambition was a great stimulus to Arctic exploration from the days of Barents, Baffin, and Hudson near the opening of the seventeenth century till the time of Sir John Franklin in the middle of the nineteenth century.

The commercial incentives for polar exploration thus predominated until far into the nineteenth century and were strongest in the north near the seafaring nations, with the result that while the unknown area of the Arctic regions is now only about as large as European Russia, that of the Antarctic domain is double the size of Europe.

The fact that the largest discoveries of the eighteenth century were made by sailors, that period being an era preëminently of the survey of coast lines and the discovery of islands, had the effect of stimulating voyages both into Arctic and Antarctic territory for geographical purposes; but the era of scientific research in the polar regions scarcely began till the first half of the nineteenth century. The humanitarian impulse that led many expeditions to engage in the search for Sir John Franklin resulted in enormous additions to our knowledge of Arctic America. In recent years the avowed purpose of the most worthy expeditions has been scientific research.

EQUIPMENT. One of the important results of polar research is the present methods and outfit for work and life in the ice zones, evolved from the experience of three centuries. The problem of fairly comfortable and hygienic existence for white men in the polar regions has been solved. For more than 250 years white men in the Arctic suffered severely from scurvy. The food supplies long included large quantities of salt meat, and until recently the dietary of Arctic whalers and explorers was almost certain to breed scurvy. If they now fall victims to this disease it is the result of great carelessness or ignorance. The art of selecting and preserving foods of healthful and great nutritive quality for use on polar expeditions has been reduced to a science. The ships employed by explorers were formerly poorly equipped for battling with the ice; but the exploring craft of the present, of which the *Fram*, *Discovery*, and *Gauss* are the best examples, are believed closely to approximate the ideal type of vessel for ice navigation. They are built with

rounded sides, so as to offer as little hold as possible to the clutches of the ice-pack, and they provide comparatively comfortable accommodations for the men. The substitution of steam for sails, the larger use of dogs instead of men at the sledge ropes, the adoption of the snowshoe and Norwegian ski in snow work, the great improvements in sledges, the utilization of Arctic game for food and to a considerable extent of the methods of living, the boats, the snow houses, and some other appliances of the Eskimos, have been very helpful factors in recent exploratory work.

NORTH POLAR EXPLORATIONS.

Fully one-half of the area of the Arctic regions consists of well-known land, of which, however, only small portions in Northern Russia, Sweden, Norway, and Alaska are inhabited. Scattered Eskimo huts dot the seacoasts of the north coasts of America, the Parry Archipelago, and Greenland, and hunting bands of Samoyedes winter in Nova Zembla.

The archipelago of Franz Josef Land, New Siberia, Spitzbergen, and Wrangell Land in the Eastern Hemisphere, and all lands to the north of the 79th parallel in the Western world, are uninhabited, and exploration turns in these directions.

ROUTES OF EXPLORATION. The six main approaches to the unknown Arctic Ocean and its scattered islands are the Nova Zembla or Northeast Passage; the Franz Josef or Barents Sea; the Spitzbergen or Greenland Sea; Smith Sound; Lancaster Sound (Northwest Passage); and Bering Strait.

NOVA ZEMBLA (NORTHEAST PASSAGE). After the discovery of America came efforts to find northeast and northwest passages to India. Of early English explorers, Willoughby and Chancellor in 1553 opened Archangel Bay; but Willoughby and two of his three ships were involved in the first great Arctic tragedy, the leader and his 62 men perishing of scurvy during the winter; while Burrough (1556) and Pet (1580) discovered and explored the Waigat, the strait leading into the Kara Sea, south of Nova Zembla. Most successful of early voyages were the three expeditions of a Dutchman, Willem Barents. In 1594 he traced northeastward the coast of Nova Zembla to the Orange Islands, 77° north. Failing next year to pass the Waigat, Barents sailed in 1596 under Jacob Heemskerck, but parted from him and rounded the North Cape of Nova Zembla. In sailing south on the east coast the party was beset and obliged to winter in Icehaven, Barents Sea. After great privations they abandoned their ship in the summer and retreated by boat to Kola, Barents dying en route. This last voyage of Barents was one of the most important of all the journeys to the unknown Arctic frontier. He showed the terrific pressure of the polar pack upon the north coast of Nova Zembla, and the existence at least occasionally of much open water to the north, a fact that has expedited many voyages to and from Franz Josef Land. Out of Chancellor's voyage arose the Muscovy Company, to the incalculable advantage of English commerce. From Barents's voyage eventually resulted the Dutch whale fisheries.

Russian energy, taking up the problem, outlined between 1636 and 1648 great extents of coast line. Among the explorers who achieved prominence were Elisé Busa, who traveled

between Olenek and Yana, and Simeon Deshneff, whose voyage from Kolyma to Kamtchatka (1648) determined the separation of Asia and America. A century later came 'the great survey' and a score of expeditions. Chariton Laptieff and Tchelyuskin discovered the North Cape of Asia (1742). Dmitri Laptieff (1737-42) skirted the coast from the Lena to Cape Baranov, thirty degrees of longitude, thus practically completing the Asiatic coast line.

Adolf Erik Nordenskjöld solved the vexatious problem of the circumnavigation of Asia and Europe. Leaving Tromsø in the *Vega*, in June, 1878, Nordenskjöld passed the Waigat and Kara Sea, rounded Cape Tchelyuskin, skirted the New Siberian Islands, and was definitely stopped by ice only 110 miles from Bering Strait. Forced to winter to the east of Cape Szerde Kamen, Nordenskjöld reached Yokohama in 1879, having made without disaster the Northeast Passage.

Another phase of Asiatic exploration somewhat related to the Northeast Passage is that of the islands of the Siberian Ocean. Liakhoff (1770) first visited the island of his name, and later added two others to the New Siberian Archipelago. He was followed by Samkiff (1805), Sirovatskoff (1806), and Bjelkoff (1808), all ivory-hunters. The daring sled-journeys of Lieutenants F. v. Wrangell and P. F. Anjou (1820-23) skirted the New Siberian and Bear islands, but had no material results, there being only open sea at Anjou's farthest, 76° 37' north, 138° east. In 1881 a northerly extension of this archipelago was discovered by De Long, commander of the *Jeannette*, as is elsewhere stated. The most notable explorations of the New Siberian Islands, yielding a wealth of scientific data, are those of Baron Von Toll, now extending over many years.

Fridtjof Nansen, a Norwegian, in 1893 passed the Waigat in the *Fram* on a novel and hazardous attempt to explore the vicinity of the North Pole by a drift voyage. The Siberian Ocean was very open, and the *Fram* was not beset until she had reached a comparatively high latitude (78° 50' N., 134° E.), northwest of Sannikoff Island, about 200 miles east of the place where her predecessor, the *Jeannette*, sank in 1881. The *Fram*, under O. Sverdrup, drifted almost uninterruptedly west-northwest until she reached 85° 57' N., 70° E., when the course changed gradually to west and southwest to northwestern Spitzbergen, where she escaped the ice after a besetment of thirty-five months. Nansen left the ship with Lieutenant Johannsen in March, 1895, on a sledge trip to reach the Pole, but unfavorable ice conditions obliged their return from 86° 4' N., 96° E. They traveled south by sledge and by kayak as the sea opened, but it was 153 days before they reached Franz Josef Land. Building a hut, they lived on the plentiful game, and, starting for Spitzbergen in the spring, were, after a hazardous journey, saved by the Harmsworth-Jackson expedition near Cape Flora in the southern part of Franz Josef Land. The *Fram* found no land in the polar ocean, but in its place discovered that from 140° E. to 10° E. the sea is of great depth, with rich fauna. It had hitherto been supposed that this part of the polar sea was shallow. Nansen in his southward journey limited the northeast extension of Franz Josef Land and traced a part of its shores.

FRANZ JOSEF LAND. Two Austrians, C. Wey-

precht and J. Payer, opened this route while exploring the Barents Sea. Their ship, *Tegetthof*, beset in 76° 22' N., 63° E., drifted northward for a year, and in August, 1873, they saw the south shores of Franz Josef Land, where the ship was abandoned in 80° N. (1874), the party reaching Nova Zembla by boat. Payer by sledge journeys explored many of the islands of Franz Josef Land, and reached Cape Fligely, 81.5° N., 58° E. English explorers followed, and in two voyages (1880 and 1881) Leigh Smith covered the coast from 54° E., Payer's westerly point, to 42° E., and while wintering at Cape Flora, owing to the loss of his ship, the *Eira*, discovered rich fauna and flora. F. G. Jackson (1894-97) established his base at Cape Flora and made extensive explorations between 42° E. and 56° E. and to 81° 20' N. Jackson rounded Alexandra Land and conclusively proved that Franz Josef Land is composed of numerous islands of limited area. It may here be added that the discoveries of White Island (2000 feet high) by Kjeldsen (1876) and New Iceland (also a frowning, high land mass) by Johannsen (1887) indicate that Franz Josef is merely an extension of the great Spitzbergen Archipelago. W. Wellman, an American, unsuccessful in Spitzbergen in 1894, renewed his efforts to reach the Pole in 1898 by way of Franz Josef Land, when E. B. Baldwin, discovering Graham Bell Land, extended the archipelago to 65° E. The Duke of the Abruzzi (1899) reached, in the *Stella Polare*, 82° 4' N., northeast of Rudolph Island, and wintered in Teplitz Bay, 81° 47' N. He explored Austria Sound, while his assistant, Captain Cagni, starting for the Pole, reached 86° 34' N., 64° E., the most northerly point attained by man, and 236 statute miles from the Pole.

THE REGION OF SPITZBERGEN. In 1598 the Dutch, under J. C. Ryp and J. Heemskereck, discovered Bear and Spitzbergen islands, exploring the west coast of the latter as far as 79° 49' N. In 1607, in one of his most remarkable voyages, Henry Hudson, the English navigator, followed the west coast to 80° 23' N., crossed Greenland Sea, discovered Jan Mayen, and sighted East Greenland in 73° N. Hudson's discoveries led later to the very lucrative whale fisheries.

THE GREENLAND SEA. Numberless whalers explored every sound and inlet during the seventeenth and eighteenth centuries for commercial purposes. Efforts toward geographical exploration northward in this region have been singularly fruitless. Phipps (1773) reached 80° 48' N., 20° E., only 25 miles beyond Hudson (1607). Scoresby, the elder, attained, in 1806, 81° 30' N., 19° E. Nordenskjöld and Otter reached 81° 42' N., 18 E. Parry in his wonderful boat and sledge journey (1827) pressed on to 82° 45' N., 18° E., the highest ever attained in the Greenland Sea.

THE SPITZBERGEN ARCHIPELAGO. Scientific exploration of the archipelago began in the nineteenth century with Clavering and Sabine (1824), and the French commission, Fabre, Gaimard, Martins, and Marnier (1838). Most notable of countless explorations in recent years are the following: Torrell and Nordenskjöld (1861) first visited Northeast Land, reaching Cape Platen and Phipps Island, 80° 42' N.; Carlsson (1863) first circumnavigated Spitzbergen; Nordenskjöld (1872) first crossed Northeast

Land from Otter Island to Wahlenberg Bay; Leigh Smith (1871) traced and rounded Northeast Land to Cape Smith on the east coast, and reached $81^{\circ} 30' N.$, $18^{\circ} E.$; Conway (1896) crossed in several ways the main island, and surveyed 600 square miles of the ice-free interior. Danes Island (1897) was the base of the tragic balloon voyage of Andrée (q.v.).

Of easterly extensions of the archipelago, opinions widely differ as to Giles and Wiche Lands. Possibly White and New Iceland islands, already mentioned, are the Giles Land of 1707. Wiche Land of Edge (1617) is probably King Charles Land, which, rediscovered from Mount White by Nordenskjöld (1864), was first visited by Nilsen (1872).

EAST GREENLAND. Nor has this route to the far north been much more successful as regards East Greenland. After Hudson saw the coast in 1607, at $73^{\circ} N.$, it was observed occasionally by whalers as follows: Hamke (1654), $74.5^{\circ} N.$; Ruys (1655), $73.5^{\circ} N.$; Edam (1655), $70^{\circ} N.$; and Lambert (1670), $78.5^{\circ} N.$ W. Scoresby, Jr. (1822 and later), discovered Scoresby Sound and charted 800 miles of coast between 69° and $75^{\circ} N.$, giving the first correct idea of the coast. Sabine and Clavering (1823) explored the coast from Pendulum Island to Shannon Island, $75^{\circ} 12' N.$ Koldewey and Payer (1870) reached $77^{\circ} 1' N.$, the highest point attained by this route. What is more important, they discovered and explored Franz Josef Fiord, penetrating inland five degrees of longitude to $73^{\circ} 11' N.$, $26^{\circ} W.$ The Danish sea captain Wandel (1879) surveyed the coast from a distance of about six miles between 66° and $69^{\circ} N.$ Graah (1829), Holm (1883-85), and Ryder (1902) did excellent work south of the Arctic Circle; Peary's crossing is elsewhere mentioned. Naero (1900) reached $75^{\circ} 30' N.$, the highest by ship in modern times.

LANCASTER SOUND AND THE NORTHWEST PASSAGE BY SEA. The first great advance toward the Northwest Passage came through three voyages of John Davis, who discovered the strait afterwards named for him in 1585, reaching the vicinity of what is now Godthaab, Greenland. Failing in 1586, Davis in 1588 by a voyage of reckless daring reached Sanderson's Hope, about $72^{\circ} 12'$, and, turning westward in his tiny craft, passed through the dreaded middle ice of Baffin's Bay to the west shore. His discoveries covered West Greenland from Cape Farewell to Sanderson's Hope, and the American coasts from Labrador to Cumberland Island. He was followed by another great English sailor, William Baffin, in the *Discovery*, of only 55 tons, with which, reaching Baffin Islands, he crossed the bay of his name by the 'Middle Passage,' passed Cape York, and on July 5, 1616, was in Smith Sound in sight of Cape Alexander. His latitude of $77^{\circ} 45' N.$ remained unequalled in this sea for 236 years. Baffin added to geographical knowledge Ellsmere and Prudhoe lands, and the sounds of Smith, Jones, and Lancaster.

John Ross in 1818 penetrated Lancaster Sound some fifty miles, but, meeting heavy ice, mistook it for a closed bay. He was followed in 1819 by one of the ablest of Arctic explorers, William E. Parry, who opened to the westward a series of magnificent waterways: Lancaster Sound, Barrow Strait, Melville Sound, and Banks Strait, leading through the Parry Archipelago to the Arctic Ocean. Parry's route, along the 74th

parallel, was to the north of the magnetic pole, the compass variation changing gradually from $109^{\circ} W.$ to $180^{\circ} W.$, and thence to $166^{\circ} E.$ Land journeys of his party in 1820 explored the vicinity of their winter quarters at Melville Island. Parry's second voyage, only important in relation to Franklin's land journeys, explored (1821-23) Repulse Bay and Melville Peninsula. In his third voyage (1825) the *Fury* was lost in Prince Regent Inlet. The expedition of John Ross, of unprecedented length (1829-34), explored Boothia Felix Peninsula, the northern extremity of the American continent, and King William Land, together with adjacent waterways. Most important was the location by his nephew, James Clark Ross, of the north magnetic pole in $70^{\circ} 5' N.$, $96^{\circ} 44' W.$

The voyages of the Englishman Lyon (1824) to Repulse Bay and of Back (1836) to Hudson Strait were fruitless, and it remained for the Franklin expedition to solve the problem of the Northwest Passage, partly by its own efforts and largely through relief voyages. Successful Antarctic work had renewed interest in the Arctic, and Sir John Franklin was despatched from England with two ships and 129 men to make the Northwest Passage. Franklin, wintering in 1845 at Beechy Island, explored the adjacent regions to $77^{\circ} N.$ Sailing south to the west of North Somerset and Boothia, his ships were beset in September, 1846, near King William Land, in $70^{\circ} 5' N.$, $98^{\circ} 23' W.$, within 90 miles of the known sea off the American continent. The only recovered record found by Hobson of McClintock's party in 1859 shows that the ships were abandoned April 22, 1848, Franklin and 23 others having previously died. Captain Crozier with 105 men perished in an attempt to reach Fish River. Their route, via King William Land, Todd and Montreal islands, is marked by graves and skeletons. The party practically vanished from human knowledge until Rae, in 1854, and McClintock, in 1859, revealed its fate.

Franklin's absence caused many search expeditions, which were remarkably fruitful in the exploration of the American Arctic from the west coast of Greenland westward. The voyages from the Atlantic of James C. Ross, W. Penny, A. Stewart, John Ross, E. J. DeHaven, C. Forsyth, and W. Kennedy discovered no trace of the explorer, though they added something to geographical knowledge. The efforts of T. E. L. Moore and H. Kellett from Bering Strait were also fruitless, except for the discovery of Herald Island. More successful was the voyage (1850-53) of Captain Collinson, who navigated the *Enterprise* through ten degrees of longitude along the coast of America, and safely back to Bering Strait. Wintering in Cambridge Bay, Victoria Land, he explored its southern shore, looked across the sea where Franklin's ships had sunk, though that was unknown to him, and even picked up relics of the squadron.

R. McClure (1850-54) from Bering Strait carried the *Investigator* to Banks Land, which he explored, as well as Prince Albert Land to the east. Wintering three years, he finally abandoned his ship in Mercy Bay. Through a sledge party which was sent to seek him, McClure learned of Belcher's squadron at Beechy Island, and this he joined by sledge, thus making the only north-west passage. H. Austin's squadron, via Lancaster Sound from the Atlantic, first saw traces

of Franklin, Ommaney finding in August, 1851, three graves at Beechy Island. Brown, Ommaney, Osborn, Aldrich, Bradford, and McClintock of Austin's party traveled by sledge 3340 miles, and discovered 670 miles of coast to the westward of winter quarters at Griffith Island (1850-51). Edward Belcher commanded (1852-53) another squadron of five ships sent out by the British Admiralty. McClintock, Meham, Nares, Hamilton, Pim, and Domville fruitlessly searched adjacent lands in journeys that aggregated 5892 miles, of which McClintock, the greatest of Arctic sledgemen, traveled no less than 1401 miles. Belcher brought home McClure's crew from the *Investigator*, but had to abandon, in 1853, two of his own ships, the *Intrepid* and the *Resolute*. The latter, drifting south, was picked up in 1854 by an American whaler, was bought by the United States, and was refitted and returned to Great Britain. The nation having failed to find certain traces of Franklin, Lady Franklin sent McClintock in the *Fox* on a search expedition. Beset in Baffin's Bay, McClintock, after a winter drift of 1200 miles, pushed on in the next summer (1858), and, following Peel Sound, wintered at Port Leopold. McClintock, Hobson, and Young, covering the whole field in sledges in 1859, discovered 800 miles of coast and unraveled the mystery. Boothian natives with Franklin silver led to the finding of boats, sledges, tents, and skeletons on King William Land, and finally of a written record. This told of Franklin's besetment and death, of the abandonment of the ships, and of Crozier's retreat toward Great Fish River.

THE NORTHWEST PASSAGE BY LAND. The Northwest Passage also involved land journeys, which began with Hearn's explorations from the Hudson Bay post, Fort Prince of Wales, in 1771, when, traveling with an Indian war party, he reached the mouth of the Coppermine, 67° 48' N. One of the Northwest Fur Company, Alexander Mackenzie, started from Fort Chipewyan to trace the waters of Slave Lake to the sea. Undeterred by tales of hardship and disaster, with Indian guides he reached, in July, 1798, Whale Island, 69° 14' N., at the mouth of the great river that bears his name. Mackenzie's successor, John Franklin, was the most notable figure associated, whether by land or sea, with the Northwest Passage. Coöperating with Parry, at sea, in 1819 Franklin pushed his advance posts by winter journeys to Fort Enterprise, 64° 28' N., 113° W. Accumulating supplies on the Coppermine, in 1821 he reached the mouth and explored the sea-coast eastward to Port Turnagain, 68° 18' N., 109° W., turning back the same day that Parry sailed out of Repulse Bay, 539 miles distant. In 1825, acting in concert with Beechy in Bering Strait and Parry in Lancaster Sound, Franklin established his base at Fort Franklin, Great Bear Lake. In 1826, reaching the mouth of the Mackenzie, Franklin coasted westward, while John Richardson explored to the east. Franklin was turned back at Return Reef, 70° 26' N., within 160 miles of Port Barrow. Richardson in a successful journey rounded Cape Bathurst, discovered Wollaston Land, and reached Cape Hope, 68° 58' N. He had traced the continental coast line through 20 degrees of longitude and 2 degrees of latitude, discovered a new land, determined tidal conditions, and made valuable geological and botanical observations.

In 1833 G. Back, wintering at Fort Reliance, Great Slave Lake, discovered the Great Fish or Back River, and the following year passed beyond its mouth to Port Ogle, at the east entrance of Simpson Strait.

In 1837 two employees of the Hudson's Bay Company, P. W. Dease and T. Simpson, operating from Fort Chipewyan, reached in 1837 Port Barrow to the west, and, wintering at Fort Confidence, explored in 1838-39 the continental shore line to the east, reaching Cape Herschel, 68° 41' N., 89° W. It remained for John Rae practically to complete the exploration of the north coast of America. From Repulse Bay, in 1846-47, Rae proved that Boothia Felix was a peninsular extension of North America, and connected with the discoveries of Parry and Ross by sea. It fell, however, to Capt. C. F. Hall, an American, in 1868 to trace the west coast of Melville Peninsula, the last unknown shore between the farthest of Rae in 1846 and of Parry in Fury Strait in 1825. In the Franklin search the northern coasts of America were examined by J. Richardson and Rae (1848-49); the latter visited Wollaston Land in a boat expedition which brought him within fifty miles of Franklin's farthest, the nearest approach to the Northwest Passage by sea. Rae in 1854 wintered at Repulse Bay, and the following April fell in with Eskimo, who gave him the first news of the Franklin disaster, reinforcing their story of the retreat on King William Land by silver bearing the Franklin crest. The last search for news of Franklin was made in 1878-79 by F. Schwatka and W. H. Gilder, who found in King William Land graves, skeletons, and relics.

SMITH SOUND. E. A. Inglefield by his voyage of 1859 opened waterways to the north, as he reached 78° 28' N., off Cape Sabine. He also penetrated far into Jones Sound and charted 600 miles of new coast. In 1853 Dr. E. K. Kane of Philadelphia pushed the *Advance* through Smith Sound into Rensselaer Harbor, 78° 3' N., 71° W. His surgeon, Dr. I. I. Hayes, traced the east shore of Grinnell Land to Cape Frazer, 79° 43' N., and W. Morton, a member of Kane's party, passing Humboldt glacier, reached Cape Constitution, 80° 35' N., whence he viewed Kennedy Channel to Mount Ross. In 1855 Kane abandoned his ship and retreated safely to Upernivik by boat. Hayes in the *United States* returned to Smith Sound in 1860, wintering his ship in Foulke Fiord and penetrating the inland ice some forty miles. In 1861 by a sledge journey he reached the vicinity of Cape Goode, Grinnell Land, about 80° 11' N. Captain Hall succeeded better, and in the *Polaris* (1871), passing Kennedy and Robeson channels, entered the Arctic Ocean near Repulse Harbor, 82° 11' N., the highest northing then attained by ship. Forced southward by ice, he anchored in Robeson Channel, under lee of a huge floeberg, explored adjacent parts of Greenland, and charted the Grinnell Land to its northern extremity beyond the 83d parallel. Hall died that autumn, and the *Polaris*, returning south in 1872, was wrecked near Littleton Island. Part of the crew under Captain Tyson drifted in the ice-pack five months, 1300 miles, and were saved off Labrador by the *Tigress*. Others wintering at *Polaris* boat-house were rescued in 1873 near Cape York.

George S. Nares in 1875 commanded a British squadron, of which the *Discovery* wintered in

Lady Franklin Bay, while the *Alert* was pushed into the Polar Sea to Floeberg Beach, 82° 25' N., on the northeast coast of Grinnell Land. The members of this party made several notable sledge journeys. L. A. Beaumont from Discovery Harbor extended the northern shores of Greenland from Cape Bryant to Cape Britannia. P. Aldrich traced Grinnell Land to Cape Columbia, 83° 7' N., and thence westward to Cape Alfred Ernest, 86° W., 220 miles of new coast. Lieutenant Areher explored a fiord of his own name. A. H. Markham, taking to the frozen sea, attained 83° 20' N., then the highest north.

Next came the American contribution to the international polar expedition under A. W. Greely, which primarily devoted itself to scientific observations, magnetic, meteorological, tidal, pendulum, etc., from 1881 to 1883. The commander explored the great glacial lake system of interior Grinnell Land. J. B. Lockwood and D. L. Brainard later crossed Grinnell Land to the southeast, discovered Greely Fiord, and extended that inlet to Cape Lockwood, about 83° W., 80° N. These inland journeys added about 6000 square miles of new land, developed fertile valleys, and plentiful animal life in a land thought to be largely ice-capped.

Lockwood and Brainard, accompanied by a supporting party to Cape Bryant, discovered a new archipelago north of Greenland, and attained 83° 24' N., 43° W. They located Cape Washington, 83° 35' N., 38° W., and determined that there was no land in the Arctic Ocean far beyond the 84th parallel. It was then the highest north ever attained, and Peary's explorations show this archipelago to be the most northerly known land. In 1884 the Cape Sabine region was explored by the Greely expedition, when F. Long discovered Schley Land, at the head of Hayes Bay. Nordenskjöld (1883) from Disco Bay reached an elevation of 6600 feet on the inland ice of Greenland in 68° 32' N., 43° W., more than half way to the east coast. Nansen's crossing (1888) was not a polar journey. The most persistent explorer of Smith Sound is R. E. Peary, who has passed parts of eight years therein. In 1886 he ascended the inland ice fifty miles from Disco. In 1892, with one companion, Eivind Astrup, he crossed from McCormick Bay to Independence Bay, 450 miles in a direct line. He repeated this trip in 1895. These difficult journeys, over an ice-cap 8000 feet high, defined the northeast limit of Greenland, 81° 37' N., 34° W., some 200 miles north of Lambert (1670) on the east coast. In his latest voyage (1898-1902) Peary established the continuity of Ellesmere and Grinnell lands, west of Hayes Bay, and also crossed from near Cape Hawkes to the vicinity of Greely Fiord on the west coast. In 1900, passing Cape Washington of Lockwood, he left the solid ground in 83° 39' N. (the most northern known land), and reached 83° 50' N. on the Arctic ice-pack. Peary's farthest east, 83° N., 35° W., determines the limitation of the northeast coast of the archipelago above Greenland. In 1901, leaving Cape Hecla, Grinnell Land, he attained 84° 17' N., 65° W., the record latitude in the Western Hemisphere. O. Sverdrup, wintering in the *Fram* in Kane Basin (1898-99) and in Jones Sound (1899-1902), proved the continuity of Ellesmere Land by tracing its western shores from Belcher's farthest in Jones's Sound to a point north of Greely's Fiord, within 60 miles of

Aldrich's farthest. Sverdrup also discovered and traced the coasts of three islands, to the westward of Ellesmere Land, the largest extending from about 79° to 83° N., and two others being between 78° and 80° N., and from 92° to 106° W.

BERING STRAIT. This was the last attempted route for polar exploration, but the results of expeditions that proceeded via Bering Strait are by no means unimportant. V. Bering's voyage of 1728 added nothing to the discoveries of Deshneff in 1648. The great English navigator James Cook attained in 1778 70° 44' N., near Icy Cape, Alaska. In 1826 Otto v. Kotzebue discovered Kotzebue Sound, not seen by Cook. The British expedition of F. W. Beechey reached by ship 71° 8' N., 164° W., while his boats under Elson attained Point Barrow, the most northerly point, except Boothia Felix, of the continent of America. The voyages of the *Enterprise* and *Investigator* are mentioned under the Northwest Passage. In 1849 H. Kellett, R.N., discovered Herald Island, and in 1855 John Rodgers of the American navy reached in that sea the highest point gained up to that time, 72° 5' N., 175° W. An American whaler, T. Long, discovered Wrangell Island, sailing along its south coast in 1867. The most daring and important expedition through Bering Strait was that under Commander G. W. De Long, who sailed in the *Jeanette* in 1879. Beset by the pack, he was unable to winter at Wrangell Land, but, drifting westward past its north coast, he exploded the theory that it was a continent extending across the North Pole. An east-by-north drift continuing, the De Long Islands were discovered in 1881, G. W. Melville landing on Jeannette Island, in 76° 47' N., 159° W. The *Jeannette*, crushed by ice, sank June 12, 1881, in 77° 15' N., 155° E. De Long retreated southward toward the New Siberian Islands, being carried while marching to 77° 36' N., 155° E., the most northerly point ever reached in that sea from Bering Strait. Separated by storm and entering the Lena Delta by different channels, De Long and Melville met different fates, the former perishing of starvation with most of his party, while Melville brought his men to safety and afterwards, by a sledge journey into the Delta, ascertained the fate of his leader. De Long perished, but his plan was taken up and pushed to success under the daring leadership of Nansen, described under the Nova Zembla route.

ANTARCTIC EXPLORATIONS.

Practically without land fauna or flora, uninhabited, and far from adventurous nations, the Antarctic Circle is rarely visited. James Cook (1773-1774) circumnavigated this ocean, entered the Antarctic Circle at four widely separated points, and reached 71° 10' S., 107° W. There are three recognized routes of exploration to the land lying south of Patagonia, of Kerguelen Island, and of Tasmania.

PATAGONIA. The first Antarctic discoverer, an American whaler, Nathaniel B. Palmer, in 1821, discovered the Palmer Archipelago, lying north of what is supposed to be a portion of the Antarctic continent. The mass of what is believed to be the mainland is now known to extend from 63° to 70° S. and to subtend 20 degrees of longitude. Palmer met in his voyage the Russian expedition under Bellingshausen, who in an extensive Antarctic voyage added several islets,

discovered Alexander Land, and approached the great ice-barrier. Weddell (1823) found open sea in 30° W. up to 74° 15' S., 34° 17' E., with no land seen. Biscoe (1831) discovered Adelaide and other islands, 67° S., 71° W., fronting Western Palmer Land, and gave to the mainland the name Graham Land. Larsen (1893) extended the east coast some 300 miles, to 68° 10' S., finding also two snow-free islands capped by active volcanoes. The Belgian De Gerlache (1897-99) discovered Belgica Strait, west of Palmer Land, explored adjacent regions, and determined the non-existence of the reported land of Walker and Cook 150° E. He also located a submarine and continental plateau, 75° to 103° W., 70° to 71.5° S., and attained 71° 36' S., 87° 39' W., with no land in sight. O. Nordenskiöld (1902) began a series of explorations east of Palmer Land.

KERGUELEN ISLAND. In a hazardous voyage J. Biscoe (1831) skirted one-third of the Antarctic Circle, and south of Kerguelen discovered Enderby Land, 47° S., 66° E. Others have here entered the circle, without seeing land: Bellingshausen 20° and 40° W. and Nares in the *Challenger* (1874) 68° 40' S., 78° E. The Germans under Dr. Drygalski in the *Gauss* set out from Kerguelen Island on January 31, 1902, and were frozen in the ice for nearly a year in 66° 30' S., 90° E. They proved the non-existence of Termination Land and discovered a new land, to which they gave the name of Kaiser Wilhelm Land. Its extent was not learned.

TASMANIA. The most important discoveries have been accomplished by this route. The first visitors were Cook (1773), who reached 67° 31' S., 142° 54' W., and Bellingshausen (1820), who reached 67° S., 170° W., neither seeing land. Balleny (1839) first discovered land, the Balleny Islands, 67° S., 163° E., and Sabrina Land, 66° S., 120° E., and attained at sea 69° S., 172° E. In 1839 C. Wilkes discovered land at six different points between 65° 20' and 66° 20' S., and 106° to 154° E., 75 miles of mountain ranges being in sight at once, all faced by an ice-barrier. Whether these are separate islands or the continent of Antarctica has been hotly argued. D'Urville, was sighted two of Wilkes's lands also, discovered, in 1840, Adélie Island, 67° S., 140° W.

In 1841 J. C. Ross discovered Victoria Land and traced its east coast to 77° S., a mountainous, ice-capped region, with two great volcanoes, Erebus and Terror, of which the first is active. Ross thence followed east (1843) for 300 miles an unbroken ice-barrier, about 200 feet high, to 78° 10' S., 161° 27' W., then the farthest south. In 1899 Borchgrevink wintered at Cape Adare, 71° 18' S., 170° E., and explored the adjacent ice-clad regions, finding five kinds of lichens and a few insects. His magnetic observations place the south magnetic pole in about 73° 20' S., 146° E., a displacement of over six degrees of longitude from the determination of J. C. Ross (1842), 72° 35' S., 152° 30' E. Borchgrevink also followed the ice-barrier, which had apparently receded some 40 miles in 60 years, and ascending it at 78° 34' S., attained on the ice 78° 50' S., 165° W. An English expedition under Scott spent the winter of 1902 in Victoria Land, and in the succeeding summer (January, 1903) the commander, with two members of his party, by a sledge journey, reached the latitude of 82° 17' S., 163° E., on the coast of Victoria

Land. Another expedition under Armitage penetrated the interior of Victoria Land, found the ice-cap thousands of feet in thickness, and attained to 77° 21' S. and 157° E.

Urville, *Voyage au Pôle Sud et dans l'Océanie* (Paris, 1845-47); Ross, *Voyage of Discovery and Research in the Southern and Antarctic Regions*, in 1839-43 (London, 1847); Rainaud, *Le Continent Austral, Hypothèses et Découvertes* (Paris, 1893); Murdoch, *From Edinburgh to the Antarctic*, in 1892-93 (London, 1894); Bull, *The Cruise of the Antarctic to the South Polar Regions*, in 1894-95 (London, 1896); Fricker, *Antarktis* (Berlin, 1898), translated as *The Antarctic Regions* (London, 1900); Cook, *Through the First Antarctic Night*, in 1898-99 (New York, 1900); Bernacchi, *To the South Polar Regions* (London, 1901); *The Antarctic Manual*, published by the Royal Geographical Society (London, 1901); Chun, *Aus den Tiefen des Weltmeeres* (Jena, 1900); Borchgrevink, *First on the Antarctic Continent* (London, 1901); Neumayer, *Auf zum Südpol* (Berlin, 1901); Gerlache, *Quinze mois dans l'antarctique* (Paris, 1902); Balch, *Antarctica* (Philadelphia, 1902).

POLAR WHALE. The Greenland or 'right' whale. See WHALE.

POL DE MONT, pôl de mônt (properly KAREL MARIE POLYDOOR DE MONT) (1857-). A Flemish poet and critic, born at Wambeke, Brabant. He was educated at the Mechlin Seminary, and

afterwards at the University of Louvain, and became professor of the Dutch language and literature in the Athenæum at Tournai, and (1882) at Antwerp. His chief works are: *Waarheid en Leven* (1877), *Jongelingsleven* (1878), *De eerste mensch* (1879), *Lentesotternijen* (1881), *Loreley* (1882), *Fladderende Vlinders* (1885), *Zanna* (1886), a comedy in verse, *Claribella* (1893), and *Iris* (1894), besides biographies of Hendrik Conscience (1883) and of Jan van Beers (1886).

POLDER, pól'dēr (Dutch, morass). A name given in the Netherlands to that portion of dry land which was formerly below the level of the sea or the nearest river, and has been reclaimed by building a dike, called a ringvaart, around the region to be drained and brought under cultivation. On such an embankment machinery for lifting water is placed and worked by wind or steam power. Successive embankments and canals are built as the work proceeds. In North Holland in the Schermer polder four such embankments and intermediate canals were necessary in order to reclaim the lowest part of the polder. A large portion of the cultivated land of the Netherlands has thus been reclaimed from the ocean. The largest of the finished polders is that which occupies the former site of the Haarlem Lake and covers about fifty thousand acres, or about eighty square miles. At the present time still larger polders are in the course of being drained.

POLE. In geography, one of the two extremities of the axis round which the earth revolves. They are therefore situated the one on the north and the other on the south side of the equator, and equidistant from all parts of it, or in latitude 90° north and latitude 90° south, respectively. They are called the North and South poles of the earth. In astronomy, the poles, which, for distinction's sake, are denominated *celestial* poles, are those points in the heavens to which the earth's axis is directed, and round which the heavens seem to revolve. The celestial poles are valuable points of reference to astronomers and geographers, so that the determination of their position in the heavens is a matter of the greatest importance. Unfortunately, no stars mark their exact situation (see **POLE STAR**), though there are minute telescopic stars only a few seconds from the North Pole. The position of the polar point is determined in the following manner: A bright star (generally the Pole star) is selected, and its position in its upper and its lower culminations (q.v.) is accurately noted, with the meridian circle (q.v.); the point midway between these two positions of the star is the pole of the heavens. The observation of the two positions of the star must be corrected for refraction, and it is for this reason that the Pole star is selected, since the effect of refraction is much the same in both positions of the star. The term 'pole' has, however, a wider application in astronomy, as in spherical geometry, denoting the extremities of a line passing through the centre of a great circle perpendicular to its plane; thus, we have the poles of the horizon (zenith and nadir), the poles of the ecliptic, the poles of a meridian. Pole in physics denotes those points of a body at which its attractive or repulsive energy is concentrated. See **TERRESTRIAL MAGNETISM**.

POLE (of a magnet). See **MAGNETISM**.

POLE, REGINALD (1500-58). The last Roman Catholic Archbishop of Canterbury. He was born at Stourton Castle, Staffordshire, in March, 1500, the son of Sir Richard Pole, by Margaret, Countess of Salisbury, daughter of the Duke of Clarence, the brother of Edward IV. His early education was received from the Carthusians at Sheen, whence, being liberally provided for by Henry VIII., he passed to Magdalen College, Oxford, and, although still a layman, received several valuable preferments through the favor of the King. For the further prosecution of his studies he went, in 1521, to the University of Paris, and thence to Padua, where he formed the friendship of a distinguished group of scholars and friends, all of whom subsequently took a leading part in public affairs—Contarini, Bembo, Sadoleto, and others. In 1527 he returned to England, where the highest ecclesiastical dignities awaited his acceptance. In 1529-30 he was in Paris, where he collected opinions favorable to Henry VIII.'s divorce from Catharine of Aragon, but on his return he courageously endeavored to dissuade the King. In 1532 Pole was again on the Continent, whence he issued his *Pro Ecclesiasticæ Unitatis Defensione* (1536), taking strong grounds against the divorce. At the end of 1536 he went to Rome, where he was ordained deacon and made a cardinal. In February, 1537, he was appointed Papal legate to England, but his commission was not then discharged. His position had greatly enraged Henry, whose resentment fell upon his elder brother, and upon his aged mother, the Countess of Salisbury. During the rest of Henry's reign Pole remained in exile. The Papacy, for the maintenance of whose authority in the cause of the injured Catharine Pole was regarded as a martyr, treated him with distinguished favor. He was employed in many affairs of the highest importance, being sent as legate, in 1537, to France and the Low Countries, from both which States Henry VIII. in vain demanded his extradition. He also took an active part in the discussion on the Interim, and when the Council of Trent was opened, he was appointed one of the three legate-presidents who acted in the name of the Pope, Paul III. On this pontiff's death in 1549, Pole was all but elected to succeed. For some time after this he resided chiefly in a monastery, near Verona, in comparative retirement, until the accession of Mary called him back to active life, as the main instrument of the reconciliation of England with the Papacy. On November 24, 1554, Pole solemnly entered London as legate, possessing in equal degree the confidence of the Queen. In the arduous charge thus intrusted to him he acquitted himself with much prudence, and, considering the circumstances of the time, with singular moderation. In the severities which marked the later history of Mary's reign it is all but certain that Pole had no share. He was ordained priest March 20, 1557, and consecrated Archbishop of Canterbury two days after, and later made chancellor of the universities of Oxford and Cambridge. On the difficult and critical question of the disposal of the Church property confiscated by Henry VIII., Pole, who saw the necessity of moderation, was for a time at issue with the Pope; but his representations were successful in producing a more moderate policy, and the work of reunion appeared to proceed with every prospect of a complete and permanent issue, when it

was interrupted by the death of the Queen, November 17, 1558. Pole died within twelve hours afterwards. Besides the treatise *De Unitate*, already mentioned, he is also the author of a book *De Concilio*, and of other treatises on the authority of the Roman pontiff and the reformation of England, and of many important letters, full of interest for the history of the time. Consult his *Life* by A. Zimmermann (Regensburg, 1893); also a study of the first and last parts of his life by F. G. Lee (London, 1887).

POLE, WILLIAM (1814-1900). An English engineer, musician, and writer on whist. He was born at Birmingham, studied engineering there, became professor of engineering at Elphinston College, Bombay (1844), and in 1850 was employed in calculations for the Menai Bridge. After acting as assistant to James Meadows Rendel and to Sir John Fowler, he entered business independently in 1858, and in 1871 was made consulting engineer of the Japanese Government. He was a prominent musician, being musical examiner in London University from 1878 to 1891, and as an authority on whist ranks with Henry Jones. Pole's works are: *On the Strength and Defects of Beams* (1850); *Iron as a Material of Construction* (1872); *Life of Siemens* (1888); *The Theory of the Modern Scientific Game of Whist* (1865, and often); *The Philosophy of Whist* (1883 and often); *The Evolution of Whist* (1895); *The Philosophy of Music* (1877; 4th ed., 1895), and *Mozart's Requiem* (1879).

POLE, WILLIAM, JR. (1852—). An English playwright, born in London. Turning his attention to the stage in 1876, he became manager of Royal Victoria Hall, London (1881-83), and stage manager of F. R. Benson's company (1883-84). In 1895 he founded the Elizabethan Stage Society, a natural outcome of his endeavors to revive interest in the Elizabethan stage and drama. Under his management have been produced *Hamlet*, without scenery (Saint George's Hall, 1881); Webster's *Duchess of Malfi* (Independent Theatre, 1892); *Measure for Measure* (Royalty Theatre, 1893); Marlowe's *Dr. Faustus*; *Arden of Feversham*; Ford's *Broken Heart*; Ben Jonson's *Sad Shepherd* and *Alchemist*; Milton's *Samson Agonistes*; Fitzgerald's translation of Calderon's *Life's a Dream*; Kālidāsa's *Sakuntalā*; Coleridge's translation of Schiller's *Wallenstein*; and other old plays. In 1884 he dramatized Howell's *A Forgone Conclusion* for the Olympic Theatre; and in 1886, Barling-Gould's *Mehalah* for the Gaiety Theatre.

POLE AND POLAR. The secant drawn through the points of contact of two intersecting tangents to a conic is called the *polar* of the point of intersection with respect to the conic, and the point is called the *pole* of the secant. Any secant of a conic through a given point *O* is cut harmonically by the curve and the polar of *O*. Two points are said to be conjugate with respect to a conic when each lies on the polar of the other. Two straight lines are said to be conjugate with respect to a conic when each passes through the pole of the other. Thus conjugate diameters are conjugate lines through the centre. When the pole is inside the conic, the tangents are imaginary, and the polar line fails to cut the conic in real points. In this case the locus of the harmonic conjugate of the pole serves as a more suggestive definition

of the polar. If the pole is on the conic, the polar becomes a tangent at the pole. The polar of the focus is the directrix in the ellipse, hyperbola, and parabola (q.v.). A few of the relations which give remarkable power to the theory of polars in the domain of geometry are: (1) The polars of collinear points with respect to a conic are a pencil of lines passing through the pole of the line, and conversely. (2) If the vertices of a triangle are the poles of the sides of another triangle, the vertices of the latter are the poles of the sides of the former. Such triangles are said to be conjugate to each other with respect to the conic. (3) If the sides of a triangle are the polars of its own vertices, the triangle is called a self-conjugate triangle. (4) The poles and polars of the lines and points of rectilinear plane figures with respect to a co-planar conic form a rectilinear figure called the polar reciprocal of the given figure with respect to the auxiliary conic. The method of *reciprocal polars* obtains from any given theorem concerning the positions of points and lines another theorem in which straight lines take the place of points, and points of straight lines. (See DUALITY.) Thus a line joining two points in one figure corresponds to a point determined by two intersecting lines in the reciprocal figure. Since the pole of any line through the centre of the auxiliary conic is at infinity, the points at infinity on the reciprocal curve correspond to the tangents to the original curve from the centre of the auxiliary conic. Hence the reciprocal of a conic is an hyperbola, parabola, or ellipse, according as the tangents to it through the centre of the auxiliary conic are real, coincident, or imaginary. Pascal's and Brianchon's theorems are reciprocals. (See CONCURRENCE and COLLINEARITY.) Conjugate lines or conjugate points project into conjugate lines or points (see PROJECTION), hence the relations of pole and polar are unaltered by projection.

The relations between pole and polar were known to the ancients, but Desargues (1639) was the first to develop the theory. To Servois (1810) is due the name *pole* (in this sense) and to Gergonne (1812) the name *polar*. Steiner (1848) also treated the subject exhaustively. Hesse (1837, 1842) introduced the notion of polar triangles, polar tetrahedra, and systems of conjugate points as the geometric expressions of analytic relations.

The terms 'pole' and 'polar' have other meanings in mathematics than those already mentioned. The centre from which radii vectors are drawn in a system of polar coordinates (see COÖRDINATES) is called the pole. The extremities of the diameter of a sphere, perpendicular to one of its circles, are called poles of the circle. If the sides of a spherical triangle are arcs of circles, whose poles are the vertices of another triangle, the latter is called the polar triangle of the first. It is shown in geometry that if one triangle is the polar of another, the second is a polar of the first. For the bibliography of the subject of polars of various orders, consult Joachimsthal in the *Nouvelles Annales de Mathématiques* (1850); *Intermédiaire des Mathématiciens* (1896). For the theory of the subject, consult Reye, *Geometrie der Lage* (Leipzig, 2d ed., 1882-86; English ed., New York, 1898); Salmon, *Higher Plane Curves* (Dublin, 1852).

POLEBURN. A disease of tobacco (q.v.).

POLECAT (probably from Fr. *poule*, hen + Eng. *cat*; hardly from *Pole* + *cat*, or from OF. *pulent*, stinking + Eng. *cat*), or **FITCHET**. The largest of European martens (*Putorius fœtidus*), the length of the head and body being about eighteen inches, the length of the tail more than five inches, and the form stouter than that of the weasel. Its color is a deep blackish brown; the head, tail, and feet almost black, the under parts yellowish, the ears edged with white, and a whitish space around the muzzle. The hair is of two kinds—a short, woolly fur, which is pale yellow, or somewhat tawny; and long shining, darker hairs. (See Plate of FUR-BEARING ANIMALS.) There is a pouch or follicle under the tail, which exudes a yellowish, creamish substance with a fetid odor; and this odor is particularly strong when the animal is irritated or alarmed. Hence its name *foumart* (foul marten), which, with various provincial modifications, is prevalent in most parts of Great Britain.

The polecat was much more common in Great Britain in former times than now, and is almost extirpated from some districts, through the constant war waged against it. It eats everything that the game-keeper wishes to preserve and is extremely destructive in the poultry-yard. The ferret, however, is only a semi-domesticated race of this species, its natural energies controlled for the pursuit of vermin. The skin is used as a fur under the name of *fitch*, and is similar but inferior to that of the marten. The long hairs, pulled out by the furrier, are utilized for making artists' brushes.

The 'polecat' of North America is the skunk, and that of South Africa is a badger (qq.v.).

POLE FLOUNDER. An elongated species of flounder (q.v.), called in Great Britain 'eraig fluke,' which is found in rather deep water on both coasts of the Atlantic as far south as France and Cape Cod. It is occasionally taken in great numbers in beam-trawls off the coast of New England, and is highly valued as delicate food, perhaps equal to the sole. Its Linnæan name is *Glyptocephalus cynoglossus*. A nearly related species on the Pacific coast is small, thin, and unappetizing.

POLEMON (Lat., from Gk. *Πολέμων*). A Greek geographer of the second century B.C., surnamed the Periegete. He was born in the district of Troas, but afterwards removed to Athens, where he obtained the citizenship about B.C. 200. After traveling through Greece, he wrote several geographical works, which were almost the first to contain special references to inscriptions, dedications, famous paintings, and public monuments of all kinds. His works are frequently quoted by later writers, including Athenæus and Pausanias. The few extant fragments have been collected by Müller, in his *Fragmenta Historicorum Græcorum* (Paris, 1841), and by Preller (Leipzig, 1838).

POLEMONIA'CEÆ (Neo-Lat. nom. pl., from Gk. *πολεμώνιον*, *polemōnion*, a plant, probably valerian, or perhaps named in honor of the Athenian philosopher Polemon, or of a king of Pontus of the same name; popularly derived from *πόλεμος*, *polemos*, war, being alleged to have been the cause of war between two kings). **THE POLEMONIUM FAMILY.** A natural order of 8 genera and about 200 species, mostly herbs, natives of temperate countries and

particularly abundant in Western North America, a few occurring in Europe, Asia and South America. Some of the species are favorite garden flowers, as *Polemonium æruleum*, *Cobæa scandens*, and species of *Phlox*, *Gilia*, etc. *Polemonium æruleum*, Jacob's ladder or Greek valerian, is abundant in the Western mountains of the United States and far north. It has a stem from one to two feet high, pinnate leaves, and a panicle of blue (or white) flowers. The chief genera are *Phlox*, *Gilia*, *Cobæa*, *Polemonium*, and *Collomia*.

POLESIAN. A brachycephalic people between White and Little Russia, bounded on the north by Grodno and Minsk, on the south by Volhynia, and on the west by Poland. They are isolated in the marshes of Pinsk and along the swamps of the Pripet River and have a cephalic index of 85. The Polesians are supposed to have an infusion of Polish blood, which accounts for their broad heads. Consult Rittich, *Die Hauptstämme der Russen*, quoted by Ripley, *The Races of Europe* (New York, 1899).

POLE STAR, or **POLARIS.** The nearest conspicuous star to the north pole of the heavens. The second-magnitude star which at the present time goes under the name of Pole star is the star *a* in the constellation of Ursa Minor. By examining attentively the movements of the stars throughout a clear night, we observe that they describe circles which are largest for stars near the celestial equator, and become smaller and smaller as we approach a certain point (the north pole), close to which is the star above mentioned. The Pole star is, however, a little less than $1\frac{1}{2}^\circ$ from the pole, and has a small but sensible motion around it. (See **POLE**.) Owing to the motion of the pole of the heavens around the pole of the ecliptic (see **PRECESSION**), this star will in course of time (about 2100) approach to within 28' from the north pole, and will then recede from it. At the time of Hipparchus (B.C. 156) it was 12° , and in 1785 2° from the north pole. Its place can easily be found in the heavens, for a line drawn between the stars *a* and *β* (called the two pointers, from this peculiarity) of the constellation Ursa Major or the Great Bear, and produced northward for about $4\frac{1}{2}$ times its own length will almost touch the Pole star. Two thousand years ago the star *β* of Ursa Minor was the Pole star; and about 2300 years before the Christian Era the star *a* in the constellation of the Dragon was not more than 10' from the north pole; while about 12,000 years from now the bright star Vega in Lyra will be within 5° of it.

The south pole of the heavens is not similarly marked by the neighborhood of a bright star, though there is a small telescopic star very close to it.

POLE VAULTING. See **FIELD SPORTS**, and **Plate of ATHLETICS**.

POLICE (from Lat. *politia*, from Gk. *πολιτεία*, *politeia*, state, government, citizenship, from *πολίτης*, *politēs*, citizen, from *πόλις*, *polis*, city). In its broader significance, the whole internal administration of a State less the judicial power. In a more restricted sense the term police denotes that sphere of governmental activity which has to do with the maintenance of the public peace, order, and security, and the protection of the public health and morals. (See **POLICE POWER**.) In this article the use of the term is still further

restricted to that part of the State administration which is concerned primarily with the preservation of the peace and the prevention and detection of crime in urban communities. The first instance of the separation of the police magistracy from the judicial magistracy seems to have occurred in France in the fourteenth century. About the same time a military police was organized which eventually became the basis of the present French *gendarmerie*. In Paris a systematic police force soon came to be organized and before the close of the eighteenth century consisted of between seven and eight hundred men. In England the police administration was in the hands of the justices of the peace, who had under their control a small number of parish constables. Several attempts in the course of the eighteenth century were made to improve the system of London police, but it was not until 1828 that the passage of the celebrated Peel Act established a constabulary force for the city under commissioners appointed by the Crown. This has been described as the first modern police force in the world. The act provided for a thoroughly organized and disciplined corps of trained men, a regular day and night patrol, and a force of reserves to be stationed at police headquarters. Although bitterly attacked at the time, the Peel system in its main features was adopted in other cities in England. In New York City, in 1841, the police force consisted of two constables in each of the 17 wards, 100 marshals, 300 night watchmen, and 100 wardens, bell-ringers, inspectors, and so on. At the same time Boston had 22 day policemen and 200 night watchmen; Philadelphia had 24 day patrolmen and 120 night watchmen. During the first half of the century the control of the police was everywhere in the hands of the local authorities, but beginning with the year 1857 State boards of police commissioners were created for the management of the police in several of the larger cities. In 1900 the police of Baltimore, Saint Louis, Boston, and Cincinnati were still under the management of State Boards, but nearly everywhere else the old method of local control had been reestablished.

In 1854 the police system of Paris was reorganized on the lines of the English system, and other Continental cities have followed. In the metropolitan district of London this force numbers 15,000 men; in Paris, 8000; in New York, 7000; in Berlin, 4500; in Vienna, 3500; in Chicago, 3000; and in Philadelphia, 2400. The number of policemen to every 10,000 of population is 20 in New York, 24 in London, 25 in Berlin, and 30 in Paris. The total annual expenditures for police purposes amount to more than eight million dollars in London, more than eleven million in New York, more than eight million in Paris, more than three million in Berlin, and about four million in Chicago.

The system of organization of the police force varies widely with different cities. The supreme authority is usually either a single superintendent or a board. In Continental Europe the single-headed authority is most common, the *maire* or the *burgomaster* being commonly vested with the immediate control of police affairs. In the United States the same system prevails in most of the smaller cities and in many of the larger ones. In Great Britain the statutes usually require that such boards shall be bi-partisan, chiefly on account of the control which the police exercise

over the machinery of elections. The Superintendent, Commissioner, or Chief, whatever title he may bear, is the executive head of the police administration, and in general is responsible for the character of the police service. For the purposes of police administration a city is usually divided into a number of police districts or precincts. Each precinct has a detachment of police at the head of which is a captain, who is responsible for the execution of the orders of the chief, and who in turn may issue instructions to those under his command. In the larger cities officers intermediate between captains and superintendents, called inspectors, are frequently provided, and these have control of a certain number of precincts. Next below the captains in the organization are the lieutenants, or, more frequently, the sergeants. Below the sergeants are the 'roundsmen,' who are charged with the duty of seeing that the patrolmen perform their duties. The lowest officer of the police force is the patrolman, whose general duty it is to patrol a given district of territory. In addition to the patrolmen on active duty a number of reserves are usually kept at each station for use in case of emergency. Frequently, as in the public parks and in parts of the city where the posts are unusually long, mounted police are provided, and in the principal ports, as in the case of New York City, there are special harbor police. A frequent and important branch of the police service is the detective bureau, consisting of a force of men employed for their shrewdness and ability to detect crime as well as their knowledge of noted criminals. Unlike the regular patrolmen, they do not wear uniforms. Occasionally, as in the city of New York, there are also special detachments of sanitary police and bicycle squads.

From the standpoint of the relation of the police to the central Government considerable variety in principle is to be seen. Thus in Ireland, Egypt, India, and Australia the police is subject to the strict control of the central Government. In Ireland the police force is the Irish constabulary, organized in 1836, consisting of military forces under the immediate control of the central Government at Dublin. In Russia the system is thoroughly centralized. Elsewhere in Continental Europe the police administration is either directly or indirectly under central control. It is a general practice in Europe for the central Government to defray a part of the cost of administering the police. In Berlin the amount granted by the central Government is four-fifths of the cost; in London and Paris, one-third. The borough and county police of England receive a Parliamentary grant, amounting to one-half of the cost of maintenance, provided a given standard of efficiency is maintained. In American cities the entire cost of its police is defrayed by the municipal Government.

In most of the European countries a State police is maintained and is under the immediate control of the central Government. It is generally modeled after the French *gendarmerie*, which is a part of the Regular Army. In Russia the secret police is largely concerned with the suppression of political agitation. Although locally selected, police officers in the United States are regarded by the courts as State agents and not agents of the municipalities, and the municipalities cannot be held liable for the tortious acts of its police officers.

POLICE MAGISTRATE. See **MAGISTRATE.**

POLICE MATRONS. Women who are placed in charge of women and children in police stations, jails, and other places where they are detained. Elizabeth Fry (q.v.) first called attention to the deplorable condition of women in prisons and insisted upon the principle that none but women should be employed in the superintendence of women. The Society for the Improvement of Prison Discipline demanded police matrons in 1823, and the National Prison Congress cited their appointment as a requirement of prison reform in 1886. The impropriety of allowing men to search women and to care for their physical wants has only recently been recognized in the United States. The reform has been instituted entirely by women—usually Woman's Christian Temperance Union workers. In Portland and Indianapolis associations of women provided for police matrons at their own expense before the position was established by law. Portland (Maine) first established the position of police matron in 1876. Chicago, Baltimore, Cincinnati, and Philadelphia employed them at a later date. Among the States where they are required by law for the larger cities are Colorado, Pennsylvania, Massachusetts, Connecticut, Rhode Island, Nebraska, Ohio, Iowa, Indiana, Michigan, Arkansas, Illinois, and California. The movement has made marked advance since 1890. Consult *Reports of National Conferences of Charities and Corrections*; *Lend a Hand*, ii., 471; iii., 61; iv., 126; ix., 180.

POLICE POWER. The inherent power of a government to take such action and to pass such laws as may be deemed necessary for its own protection, and to secure the safety, comfort, and general welfare of its citizens. It is very difficult to define the precise limits of the police power of a government, and probably there are no absolute limits, except that it shall only be exercised for the purposes above mentioned, and such restrictions as may be imposed by a written or unwritten constitution. Chief Justice Shaw of Massachusetts expressed this difficulty as follows: "It is much easier to perceive and realize the existence and sources of this power than to mark its boundaries or prescribe limits to its exercise." The same jurist defined it as "the power vested in the Legislature by the Constitution to make, ordain, and establish all manner of wholesome and reasonable laws, statutes, and ordinances, either with penalties or without, not repugnant to the Constitution, as they shall judge to be for the good and welfare of the commonwealth and of the subjects of the same." While governments have always assumed to exercise the powers above mentioned, the law and theory of the police power as a justification and authority for otherwise arbitrary and despotic acts have been a growth of the nineteenth century. In some respects the police power is more arbitrary than that of eminent domain. By virtue of the latter a government may take private property only upon making proper compensation therefor, whereas if property is confiscated or

destroyed for the public good under the police power no reimbursement need be made to the owner.

The Constitution of the United States enumerates the powers of the Federal Government, which also possesses incidental power to do all acts necessary to exercise the authority thus vested in it, and this may be said to be its police power. An example of this are the United States quarantine regulations, which, in so far as they are inconsistent with the State laws on the subject, supersede the latter. However, the great bulk of the police power vested in the States is independent of the United States Government, and cannot be interfered with by Congress. One notable instance where the Federal law has superseded State regulations under their police power was where the United States courts sustained the right of dealers to import liquors and sell them in a State where the laws prohibited traffic in liquor. The United States Supreme Court held that this interfered with interstate commerce, but expressly stated that the liquor was only protected as long as it was contained in the 'original package' (q.v.) in which it was imported, thus recognizing the right of the State to regulate the liquor traffic *within* its own boundaries under its police power. Among the numerous laws and regulations of the various States which have been held to be legitimate exercises of the police power are: Acts requiring railways to fence in their tracks; requiring sign-boards at crossings; regulating the speed of trains; regulating the charges of persons in quasi-public occupations, as warehousemen, cab drivers, ferry owners, etc.; regulating the storage of explosives, the sale of poisons, and of liquor; prohibiting the adulteration of foods; regulating the employment of women and children; requiring the quarantine of infectious diseases, and destruction of infected houses and property; and the licensing of physicians, druggists, engineers, etc. Laws prohibiting labor and enforcing quiet on Sunday have been held not to encroach on the religious liberty of individuals, but to be a valid exercise of the police power for the general welfare of the community. The subject of police powers is discussed in: Cooley, *Constitutional Limitations*; Thayer, *Constitutional Limitations*; Tiedeman, *Limitation of the Police Power in the United States*; Prentice, *Police Power*. See also **CONSTITUTIONAL LAW** and the authorities there referred to.

POLICY (Fr. *police*, It. *polizza*, from ML. *politicum*, *polctum*, *poleticum*, *polyptycum*, register, from Gk. *πολύπτυχον*, neu. sg. of *πολύπτυχος*, *polyptychos*, having many folds or leaves, from *πολις*, *polys*, much, many + *πίξ*, *ptyx*, fold, leaf, from *πίσσειν*, *ptyssein*, to fold). A method of gambling, resembling the ordinary lottery in that slips, on which are printed numbers and usually some name or device for identification, are given out to the players, and corresponding numbers on slips are intermingled in some receptacle and drawn out by a blindfolded person. The players usually make bets upon the order in which numbers in a certain sequence will appear. Although the odds given the players are very alluring, the chances of winning are actually very much against them. Usually very small bets will be received, and for this reason it is quite popular among the poorer classes, especially in great

cities. Gambling in this form is prohibited in nearly all of the United States, either under the specific name of policy, or under the more general term of lottery. The United States postal laws prohibit the mailing of advertisements or tickets of policy shops, and for this reason most establishments of this sort operate in a limited locality and with some attempts at secrecy. See **GAMBLING; LOTTERY.**

The written contract by which a person undertakes to insure another against the happening of any event, or to pay him a certain sum upon a certain contingency, is called a policy. The policy is frequently designated by some qualifying word, as 'tontine,' 'endowment,' or the like, according to the nature of the insurance undertaken. See **INSURANCE.**

POLIDORO (CALDARA) DA CARAVAGGIO, pól'le-dó'ró dá ká'rá-vá'jò (c.1495-1543). An Italian painter and decorator of the Higher Renaissance. His real name was Caldara. He was born at Caravaggio, near Milan, and coming to Rome as a youth, he obtained employment as a mason upon the Vatican constructions in progress, under the direction of Raphael. He was instructed in painting by Maturino, a Florentine, with whom he afterwards formed a partnership. The two together executed a great number of decorations in *sgraffito* (q.v.), the subjects of which were generally of a historical or mythological character and were remarkable for the acuracy of the archaeological detail, and the effectiveness of their plastic handling. These decorations, both in the Loggie of the Vatican and upon the façades of Roman palaces, have mostly perished, but they are well known from engravings. The sack of Rome in 1527 and the death of Maturino drove Polidoro to Naples, where he developed a powerful realistic style, which exercised great influence upon the character of the Neapolitan school. The picture most typical of this last phase of his art is "Christ Bearing the Cross" (1534), in the Museum of Naples. Dissatisfied with Naples, he afterwards went to Sicily, and, settling in Messina, he acquired position and wealth, but was assassinated there in 1543. Consult Bertolotti, *Artisti lombardi a Roma* (Milan, 1881).

POLIESSIE. A marshy region in the west of Russia, comprising the larger part of the Government of Minsk, the northern part of Volhynia, the eastern part of Grodno, as well as portions of the governments of Mohilev and Kiev. It is thickly wooded and noted for its unhealthy climate. The *plica polonica* is very common. A considerable area has been drained by the Government since 1873 and the reclaimed regions yield good crops of hay.

POLIGNAC, pól'le'nyák'. An ancient French family, several of whose members played a prominent part at court after the time of Louis XIV. MELCHIOR DE POLIGNAC (1661-1742) was born at Puy-en-Velay, in the Department of Haute-Loire. He was destined by his parents for an ecclesiastical career, and received an excellent education. In 1693 he was sent to Poland as ambassador, and intrigued so successfully in favor of the Prince de Conti that the latter was actually elected John Sobieski's successor in 1697. Augustus the Strong, however, proved the successful aspirant to the throne, and both Conti and Polignac had to leave Poland, in consequence

of which the latter retired to his abbey at Bonport. In 1702 he was recalled to Versailles, and rose higher than ever in the royal favor. In 1712 he was appointed French plenipotentiary at the Congress of Utrecht, and after his return obtained the abbeys of Corbie and Anchin. During the Regency Polignac took part in the conspiracy of Cellamare, and was banished to his abbey of Anchin. In 1725 he was sent to Rome, charged with the conduct of French affairs, and signalized his mission by healing the quarrel that was dividing the Gallican Church on the subject of the famous bull *Unigenitus*. (See **JANSENISM.**) In 1725 he was raised to the Archbishopric of Auch, and on his return to France spent the remainder of his days in retirement. Polignac succeeded Bossuet at the Académie Française in 1704, and was also a member of the Académie des Sciences and of the Académie des Belles-Lettres. For his life see the *Memoirs* of the time, notably those of Saint Simon and D'Argenson.

The other members of the Polignac family who deserve mention are connected with the last phases of the Bourbon monarchy in France. In the reign of Louis XVI., Yolande Martine Gabrielle de Polastron, Duchess de Polignac (1749-93), and her husband, Jules, Duke de Polignac (died 1817), were among the most intimate and favored advisers of Marie Antoinette. They obtained vast sums of the public money from their connection with the Court, and were largely if not mainly responsible for the extravagance which marked the eve of the Revolution. The Polignacs—knowing the deep hatred felt toward them by the French people—were the first of the *noblesse* to emigrate (July 16, 1789). From the Empress Catharine II. of Russia, the Duke received an estate in the Ukraine, and did not return to France at the Restoration. He left three sons, of whom only one deserves notice—JULES AUGUSTE ARMAND MARIE, Prince de Polignac, born at Versailles, May 14, 1780. In 1804 he entered with his brother into a conspiracy against Napoleon, and both were imprisoned, but they escaped when the Allies entered France, in 1814. After his return to Paris Polignac became intimate with the Count of Artois, afterwards Charles X., showed an ardent attachment to the Roman Catholic Church, and, in consequence, received from the Pope, in 1820, the title of a Roman prince. He was appointed ambassador at the English Court in 1823; and finally, in 1829, became head of the last Bourbon Ministry, in which capacity he promulgated the fatal ordinances of July, 1830, that called France to arms, and drove Charles X. from the throne. (See **JULY REVOLUTION.**) He then attempted to flee from the country, but was captured at Granville, tried, and condemned to imprisonment for life in the Castle of Ham, but was afterwards set at liberty by the amnesty of November 29, 1836. He took up his residence in England. He died at Saint-Germain, March 2, 1847.

POLILLO, pól'le'yó. A group of islands in the Philippine Islands, lying about 30 miles east of the Province of Infanta, Luzon, and connected for administrative purposes with the Province of Tayabas. The area of the group is 405 square miles, and its estimated population is 1500. The area of the chief island (Polillo) is 294 square miles; its chief town bears the same name and has a population of about 1400.

POLIORCETES, pól'i-ór-sé'téz. A surname of the Macedonian King Demetrius I. (q.v.).

POLISH CATHOLIC CHURCH IN THE UNITED STATES. See INDEPENDENT CATHOLIC CHURCH IN THE UNITED STATES (POLISH).

POLISH FOWL. A variety of poultry traceable as far back as the sixteenth century, under many names. These fowls are raised in the United States, mainly on account of their handsome plumage, the most striking feature of which is a great globular crest, or top-knot, which envelops the entire head. See Colored Plate of FOWLS, accompanying article POULTRY.

POLISH LANGUAGE. A language belonging to the western group of Slavic languages (q.v.) and occupying the second place in importance in that family. It is spoken by about 15,000,000 persons in those parts of Russia, Austro-Hungary, and Prussia which constituted the former Kingdom of Poland, and by more than 1,000,000 persons in America. Of the many Polish dialects, the following are the most important: *Great Polish* in Posen and portions of the governments of Kalisz and Plock; *Little Polish*—the most euphonious—in Galicia (Cracow and Lemberg being the centres); *Masurian*, or *Masorian*—in East Prussia and in the north-eastern part of the Polish Kingdom (Warsaw, the centre); *Lithuanian Polish*, used by Mickiewicz and other writers; *Prussian* and *Silesian Polish*—full of Germanisms. The earliest literary monuments in Polish do not go further back than the twelfth century. In its historical development the Polish language underwent many outside influences. The introduction of Christianity (c.965) brought Latin to the front at the expense of the native tongue, while the numerous German settlers introduced German words for articles of every-day life. The Reformation brought the language of the country into Church use. For about two centuries the macaronic literature (a mixture of Latin and Polish) prevailed. The pseudo-classical period brought the mania for everything French and with it the adoption of numerous Gallicisms. It was reserved for the Romanticists to purify the Polish language, and their traditions are still kept up by many purists in a struggle against the inroads of Russian technical terms and of Germanisms.

Although the combinations of sibilants in Polish look formidable on paper, they are soft in pronunciation, *sz = sh*, *cz = ch*, *rz = zh*, or *sh* after consonants. Besides the phonologic characteristics mentioned in the article SLAVIC LANGUAGES the following features of the Polish language may be mentioned: (1) Seven cases in nouns—nominative, genitive, dative, accusative, vocative, instrumental (ablative), and locative (prepositional). (2) Loss of the dual (in nouns and verbs), of which traces are still to be found, however, in various dialects. (3) All futures are compound; the simple preterites have all been lost, and periphrastic forms now take their place. (4) Invariable accentuation on the penult, which is a later substitution for the original Slavic free accent. In power and variety of expression, the Polish language fairly rivals Russian.

In other languages: Morfill, *A Simplified Grammar of the Polish Language* (London, 1884); Smith, *Polnische Grammatik* (2d ed., Berlin, 1863); Vymazal, *Grammatik der polnischen Sprache zunächst zum Selbstunterricht* (Brünn, 1884); Poplinski, *Grammatik der polnischen Sprache* (7th ed., Thorn, 1881); id., *Elementarbuch der polnischen Sprache* (14th ed., Leipzig, 1893).

POLISH LITERATURE. The 'popular' literature of the Poles falls into two main divisions: (1) lyric and (2) epic. The first, although expressing the sadness of the race, oftener treats of themes of boundless merriment and joy of life. The second group consists of tales, animal epics, apologues, religious legends, and finally historical tales, few in number. The moods are definite and calm, strong realism intermingled with humor being the rule. These are embodied in the numerous adages, proverbs, and sayings—the whole philosophy of the nation. The best collections of material on this popular literature are: *Adalberg's Book of Polish Proverbs* (Warsaw, 1894); and the monumental work of Oskar Kolberg, *The People, Its Customs, Manners, Language, Traditions, Proverbs, Usages, etc.* (Warsaw, 1865-98), of which 23 volumes have so far appeared.

WRITTEN LITERATURE. EARLIEST TIMES. With Christianity (c.965) came also the rejection of everything national as reminiscent of heathenism. The indigenous letters were replaced by the Latin alphabet and all studies in the schools had for their sole object the mastery of the Latin language. In the thirteenth century education was extended, and more than 120 different schools are known to have existed in the period of 1215-1364. But the Polish scholars, writing in Latin, are in no way representative of the Polish nation.

The literary remains of this period to the end of the fifteenth century fall into three groups: (a) *Scientific.* Annals and Chronicles of Martin Gallus (1110-35)—quite fantastic in subject-matter, but unaffected in style and humorous; Wikenty Kadlubek (1160-1223), in most artificial and labored mediæval Latin; the journeys of the Franciscan Carpini (Giovanni di Piano) and Benedict Polacus to the Tatar Khan Hayuk in the thirteenth century. The *Historia Poloniae* of Jan Dlugosz (1415-80), Bishop of Lemberg, in 12 volumes, is a remarkable result of more than two decades of independent research, and is animated by strong patriotism and written in

artistic style. (b) *Didactic*. Sermons, though delivered in Polish, were written in Latin, to give them a wider circulation abroad. They contain much anecdotic material, important for the history of literature, as well as accounts of current superstitions and ethical instruction valuable for the history of Polish morals. (c) *Poetic*. These are very few; most of the extant manuscripts contain mediæval translations of the classics. Of the Polish poems preserved in Gallus, Wikenty, and Długosz, many are poetic in spirit and feeling, though crude in form. Of these the earliest and most remarkable specimen is the famous battle hymn to the Virgin (*Bogurodzica*), ascribed by tradition to Saint Wojciech of the tenth century. Other specimens are: the *Psalter of Queen Margaret*, in a manuscript of the fourteenth century, also known as the *Florian Psalter*; a prayer-book of the year 1375; a Polish translation of the fiftieth Psalm; the Gnesen sermons; the Bible written for Queen Sophia. Some Polish statutes and religious hymns belong to the fifteenth century.

During this period humanistic ideas gained ground. The number of schools increased rapidly to satisfy the great demand for study among the laity. The contest between scholastics and humanists, raging in other parts of Europe, was carried on also in Poland. Andrzej Halka's *Eulogy of Wiclif* proves that literature was becoming a means of religious propaganda.

In the sixteenth century the Polish language was gradually superseding Latin. The first book in Polish was printed in 1521 (*The Discourse of King Solomon*), and this is commonly taken as the beginning of the new 'golden' period of Polish literature. A Protestant translation of the Bible appeared at Brześć (Brest-Litovsk) in 1553. The great names of this period are: Mikolaj Rej of Naglowice (1505-69), who gives in his poems vivid pictures of contemporary manners, typical studies in character and graphic descriptions of scenery. Jan Kochanowski (q.v.) (1530-84) is best known by his *Psalms*. His *Laments* (on the death of his daughter Ursula) are characterized by depth and sincerity of feeling, and perfection of form. His *Jests* are rollicking with fun or bitter with satire. His dramatic effort (*Departure of the Greek Envoy*) was the pioneer in Polish drama. The names most closely allied with his are those of Szarzyński, Grochowski, Peter Kochanowski, Szymonowicz, and Sebastian Klonowicz (1545-1602), a keen satirist, but not a poet, and Stanislas Orzechowski (1573-66), who perfected the Polish language in his publicist writings.

The only poet of merit that the seventeenth century produced was Maciej Kazimierz Sarbiewski (1595-1640), a writer of Latin poems. The exhaustion of the poetic vein brought about the so-called 'macaronic period' of Polish literature. The only valuable achievements were the increasing number of translations of European poets. A theatre was established by Ladislas IV., where English, French, and Italian actors appeared. There had been native mysteries, such as Rej's *Joseph*. All of them were very poor, the best being those of Andrzej Morsztyn, but even he was more an imitator of French and Italian models than a creative poet; his translations of Corneille's *Cid* and Tasso's pastoral drama *Amin-ta*, however, were excellent. Wacław Potocki's

The War of Khotin, discovered in manuscript in 1850, is a powerful realistic poem, more striking when contrasted with the general barrenness of the period. The first half of the eighteenth century served to emphasize the dangers arising from internal disorders. Martin Matuszewski (1714-65) gave vivid pictures of the moral depravity of the times. Warning voices were heard against the licentiousness of the nobility (Karwicki) and the *liberum veto* (Konarski).

PERIOD OF FRENCH PSEUDO-CLASSICISM (1750-1822). The weak King Stanislas Poniatowski was a man of high culture and strong æsthetic leanings. A philosophical reaction succeeded Catholicism, and French ideas triumphed. The consciousness of social evils prompted the writers to expose them in satire and fable, while virtuosity of form was the chief object in this anxiety to imitate the French models. Trembecki (1723-1812), Wegerski, and Krasiecki (1735-1801) armed themselves against the reigning inertia, 'barbarous' prejudices, and foolish imitation of foreign manners. Naruszewicz fell below these three in poetic gifts, but, being an historian, surpassed them in the breadth of his views; his satire was more bitter, he felt more keenly the demoralization of society. Though Pseudo-Classicalists, these writers did a great service by connecting literature with life, and their works were very popular. Comedy flourished, and the first political comedy in Polish, *The Envoy's Return*, by Niemcewicz, enjoyed great success. The greatest name in Pseudo-Classical drama is that of Alexander Fredro (1793-1876), who wrote much later, but really belonged to this period. His plays are among the gems of the Polish stage, owing to the beauty and purity of the language, the genuine wit, the live types, and the unflagging interest of the action. Along with this satirical current the sentimentalist movement found strong representatives in Krasiecki, Karpiński, and Książnin, the first being especially popular. The final partition of Poland (1795) brought a wave of patriotism. Hence the success of Niemcewicz's *Historical Ballads* (1816). Dramas cropped up in answer to the same demand for and interest in everything historical.

ROMANTICISM (1822-62). Romanticism, which placed feeling above reason, answered the condition of Poland. *The Ode to Youth* of Mickiewicz struck a responsive chord in the hearts of his countrymen. From such feelings proceeded the love for the miraculous (destined to develop into mysticism a little later) and national folklore abounding in it. The educational reforms of Czacki and Czartoryski brought more learning; the poets sought recognition from their people as a whole, and not from patrons. The lyceum at Krzemieniec, with its inspired historian Leleweł poetically reproducing the ancient times, turned out a score of students who became the disseminators of Romanticism in their poetical and critical works, all of which aimed at creating a national poetry. Among the various factors in this literary movement the so-called Ukrainian (Little Russian) school was the most prominent. Among its representatives Malczewski (1793-1826) was the bard of the nobility; Zaleski (1802-86) glorified free Cossackdom; Goszczyński (1803-76) sang with epic simplicity the customs and beliefs of the Haidamaks. Zaleski's poems appearing in 1822 passed unnoticed. A few months later another collection of poems ap-

peared, and from those the period of Romanticism was dated. These were by Adam Mickiewicz (q.v.) (1798-1855), the greatest name in Polish literature. They exposed the author to attack from the adherents of Pseudo-Classicism, but soon these were either turned into romantics or were silenced. Before long the opposition to the romantic movement resulted in the exile of Mickiewicz and others, and almost all the poets then emigrated. Closely allied with Mickiewicz were poets of nearly equal power, as Krasinski (q.v.), who began with universal ideals (in his *Undine Comedy*) and then narrowed down to pure nationalism (in *Trydion, Dawn, and Psalm of the Future*). Unlike him, Slowacki had a definite purpose. Being a pronounced democrat, he endeavored to trace in a series of poetic works the democratic tendencies in the culture and political development of Poland. Around these three great poets gathered a number of lesser lights like Zan, Garczynski, Witwicki, Gorecki, Odyniec, and others. But soon the leaders became mystics. Slowacki's poems became so misty and involved that they were no longer understood. However, the clouds of mysticism passed away, and a more speculative and calm attitude toward reality set in among the workers. Wikenty Pol represented the past in an ideal light, Sigismund Kaczkowski and Rzewuski ably seconding him in his efforts. Ludwik Kondratowicz (1823-62, pseudonym Wladislaw Syrokomla), in his stories in verse, was the inspired singer of the aspirations of peasants and the small bourgeoisie. Lenartowicz (1822-93) took his themes from popular legends, preserving their simplicity in a delicate poetic form. After the apathy immediately following the revolution of 1830-31 wore away, there grew up a group of 'enthusiasts,' who wanted another revolution. Among the poets, who, with the exception of Pol and Kondratowicz, were all for revolution, Ujejski in his *Biblical Melodies* and *Jeremiah's Lament* described Poland under the name of Judea, and his *Choral* became the national anthem. This period of storm and stress evolved two distinct currents of political and philosophical thought in Polish literature: one turbulent (poetry) tending toward revolution, the other calm (novel and romance) toward gradual evolution. The novel, which was originally purely sentimental, received its high state of perfection at the hands of Kraszewski (q.v.) (1812-87).

MODERN PERIOD (1862-1900). Kraszewski reflected in his writings all the various currents of thought, ever seeking the 'golden mean.' Josef Korzeniowski was a deeper psychologist, and preached more progressive ideas, especially combating the prejudices of the nobility. Among those who idealized reality, Chodzko, Czajkowski, and the poetess Jadwiga Luszczevska may be mentioned. Zygmunt Milkowski (pseudonym Jeż) was an energetic champion of democratic ideas, even in his historical novels, and Zachariasiewicz with Plug (pseudonym of Pietkiewicz) followed closely in his steps. This period was in the beginning very similar to that subsequent to 1831, only the hope for restoration was weakened still more. The characteristic feature was the growth of the periodical press, which soon took the lead in the spiritual life of Poland. Books were printed in cheap editions in great quantities to supply the demand

for them among the masses. Positivism, economic questions, the material and spiritual welfare of the country were now of paramount importance. The chief organs for spreading these views were the *Weekly Review* and *Truth*, of the monthlies, the *Athenaeum*, representing the progressive elements, *The Warsaw Library* being the mouthpiece of the conservatives. About the middle of the seventies the strife between the two camps lost a good deal of its bitterness. In the three parts of the former Poland all efforts are directed toward the moral and intellectual uplifting of the masses, with the Warsaw weekly, *The Voice*, as champion of the people's rights. All these economic, political, and philosophical tendencies have found expression in literature, lyric poetry being least influenced by the various currents of thought. At the head of lyric poets stands Adam Astryk (1838-97), a master of form. Marya Konopnicka pleads the cause of the 'downtrodden and oppressed' in her lyrics, and she is famous for her short stories. The two writers mentioned have also distinguished themselves in the department of drama. Wiktor Gomulicki is the 'poet of nature and feeling,' possessing an unusually tender and expressive style. The comedy of the present day deals chiefly with social questions, in a light, satirical way. It is lively and witty, the situations are natural, and the action is interesting and rapid. The most prominent writer of comedies is Fredro the younger. Historical dramas, written by Szajski and others, are not very numerous, and are not so well liked by the public as dramas of manners and social questions. Among the writers of modern dramas Aleksander Swetochowski, Wacław Karczewski, and Wladislaw Rabski hold an important place. The chief characteristics of the modern novel are a highly perfected technique and great variety in the subjects, the characters depicted, and the tendencies of the authors. For these reasons the modern Polish novel is more fully representative of the epoch than is drama or poetry. Its brightest names are Sienkiewicz, Boleslaw Prus, and Eliza Orzeszkowa. Of the latest writers Klemens Junosza has drawn in a plastic and humorous style the life of peasants, Jews, and the small nobility; Ignacy Maciejowski also depicts peasant life; Balucki lashes the shortcomings of the contemporary Polish nobility; Dygasinski deals with life in the country. Several rather unsuccessful attempts have been made to introduce novels in the style of the French naturalistic school, while other writers try to keep up the traditions of Kraszewski. The periodical *Life*, founded in Cracow in 1897 by Ludwik Szczepanski, is the organ of this so-called Young Poland, Stanislaw Przybyszewski being the literary leader.

POLITICAL AND SOCIAL SCIENCE, AMERICAN ACADEMY OF. A learned society organized in Philadelphia, December 14, 1889, and incorporated February 14, 1891. Its membership has grown rapidly and is now more than two thousand, distributed through the United States and more than 30 foreign countries. Its general advisory committee is composed of representatives of the faculties of the leading American and of several foreign universities; the president and secretary are connected with the University of Pennsylvania, where the annual meeting is held in April. Its object is the promotion of political and social science, by accumulating a library, by offering prizes for specified contributions to science, by publishing papers and reports, and by establishing lecture courses. Its publications are *The Annals of the American Academy*, a bi-monthly magazine on current political problems, which began July, 1890, with several supplements every year containing translations of foreign works, and a special series of pamphlets, containing the principal papers submitted to the Academy, of which several hundred numbers have been issued.

POLITICAL ECONOMY. The term economics, derived from the Greek words *oikos* (household) and *νόμος* (law or regulation), was used by Xenophon and in the spurious treatise attributed to Aristotle, to signify the art of prudent and systematic household management, with particular reference to family income and expenditures, and to the labor and satisfaction of the wants of the members of the household. *Political economics*, or *political economy*, as the words imply, originally signified the art of directing the industry, the consumption, the incomes and expenditures of the State and its subjects with frugality and care; and in this sense was first used in the *Traité de l'Economie Politique*, published by Monchrétien de Vatteville in 1615. The use of the word in this significance soon became general. It was not until the nineteenth century that political economy came to be commonly conceived as a neutral science, divorced from the art of statesmanship. Economics then became the science of wealth, the study of those things which possess exchange value. This view became dominant about 1825, the abstract and theoretical treatment then in favor being divided into three or four topics: the production, consumption, and distribution of wealth (J. B. Say), or the production, distribution, and exchange of wealth (J. S. Mill), most subsequent writers including exchange and a minority following Mill in excluding consumption. Some

writers (e.g. Senior, J. S. Mill) proposed to limit the term political economy to this comparatively narrow science of wealth; while others proposed to substitute for the term the titles *Chrematistics* (Sismondi), *Catallactics* (Whately), meaning the science of exchanges. A sharp reaction set in about 1850 against the attempt to increase the precision of the science by narrowing its scope. The Historical School (see below) maintained that the subject of the study was not wealth, but man's relation to wealth; that it was part of a general social science, and could not profitably be divorced from ethics and politics. The first contention, well expressed in Roscher's aphorism that political economy begins and ends in man, has met with practically universal acceptance. The other contentions of the Historical School are still in dispute, but they have served effectually to prevent any uniform acceptance of the term political economy. *Economics*, wrested from its old meaning of household management, is used or defended by Jevons, Marshall, Macleod, Ely, and other leading economists, but it is the brevity and not the clearness of the word which preserves it, since as now used it is affected with all the ambiguity of the longer title.

CONTENT OR SCOPE. The investigation of the social relations and activities connected with wealth may be divided into four stages. In the first stage we describe, classify, define, and enumerate economic phenomena. In the second we analyze and interpret these phenomena for the purpose of revealing cause and effect, of discovering uniformities and sequences or economic laws. In investigating economic uniformities we are practically forced to certain conclusions about economic progress, and the theory of economic progress determines largely our interpretation of approximate aims and ideals: the determination of these ideals constitutes the third stage. In the fourth stage we discuss means to attain these aims and ideals. We may easily distinguish the stages in which one of these processes far outweighs in importance all the rest. Corresponding to the first stage we have Economic History, Economic Methodology, and Economic Statistics; corresponding to the second stage is Economic Theory; to the third stage, the Ethics of Political Economy; and to the fourth stage Applied Political Economy, often but infelicitously called the Art of Political Economy. It should be added that Economic Theory, also called Economics, Social Economics, Theory of Political Economy, etc., is usually subdivided further into the inductive theory and the deductive theory, and the latter is frequently called hypothetical, abstract, speculative, Pure Economics or the Pure Theory. Briefly stated, the debate over the proper scope of political economy hinges about the question whether the term political economy shall be applied to all or only to a part of these divisions. Some writers (e.g. H. von Scheel, Laveleye, and most German writers) would use the term political economy to cover all of them. The leading English economists of the present time would use the term so as to include all except ethics and applied political economy; while the fast disappearing group of which Senior is the best example attempted to confine the science of political economy to abstract or hypothetical theory. This question

will be considered below, where the discussion of scope is continued in connection with that of method. In anticipation of that discussion, and following the usage of Adam Smith and the popular interpretation of the term, we may define political economy as the ordered knowledge of the social phenomena arising out of man's activity in the acquisition and use of wealth.

By wealth we mean things possessing value. We mean goods and services which usually and regularly cost labor, and which are exchangeable for labor. We mean useful things of a material nature, and personal services which satisfy human wants, which exist in quantities below the amounts desired, so that each unit of them possesses distinct importance for us.

HISTORY OF ECONOMIC THOUGHT. GREECE. Greek economic thought is characterized by an exaggerated confidence in the power of the State to mold human nature, control industry, and direct the growth of society. In political thought this resulted in a striking subordination of the individual to the State; in the study of society it led to the subordination of economics to politics and ethics. Slavery was generally indorsed—indeed it was probably regarded as indispensable by the majority. The Greek philosophers fully understood the advantages of the division of labor, and Aristotle is generally credited with having entertained correct views upon money and advanced ideas concerning value. The Greek philosophers generally condemned interest-taking and entertained the traditional prejudices against trade and commerce. This brief summary may be accepted as representing the opinions predominating among those Greek writers whose works have come down to us. To be sure, there are certain qualifications to be made to this view of Greek thought, but on the whole it is probably true that the Greeks had little or no conception of the sacred regard for the individual which characterizes the theory of modern individualism.

THE ROMANS took their philosophy from the Greeks, and though they made important studies of particular economic problems, laborious studies have utterly failed to reveal the existence of anything approaching a dominant system of economic thought. Interest-taking, avarice, and trade were generally condemned by the philosophers. Slavery was occasionally condemned—by Varro and Columella as an expensive and demoralizing industrial system, by Seneca on the general principles of the Stoic philosophy. In the Roman jurists we find evidence of systematic thought upon the nature of money, wealth, and capital; the encouragement of population, the regulation of private property and sumptuary control of various kinds, etc. But the general line of historical development is from Aristotle to the Christian Fathers, and more particularly to the mediæval Canonists.

CHRISTIANITY. The immediate effect of Christianity was to strengthen in general the prevalent Aristotelian system of economic philosophy, its condemnation of usury and the pursuit of wealth in trade, its assertion of the superiority of agriculture, and its support of the social system of status. Christianity thus strengthened the subjection of economics to ethics, but it weakened the subjection of economics to politics. Within the Church there was taught the equality of men before God, and the essential dignity of

labor. The clergy were permitted to earn their own livelihood by manual labor, and the laity were exhorted to free their slaves as soon as they became Christians.

THE MIDDLE AGES (A.D. 400-1500). Inasmuch as the teachings and doctrines of the early mediæval writers are well summed up in the *Corpus Juris Canonici* (see CANON LAW), it will be convenient to discuss them under the general heading of the Canonists—the schoolmen and theologians who after the compilation of ecclesiastical laws by Gratian in the twelfth century analyzed and expounded, among other things, the relation to economic affairs of the Scriptures, the writings of the Christian Fathers, decisions of Church councils, and Papal decrees. The doctrines of the canonists were largely derived from the Scriptural injunctions against the excessive pursuit of wealth and the payment or acceptance of interest on loans. The early Fathers in their condemnation of avarice and their exaltation of fraternal love, sometimes used expressions which taken by themselves imply an utter condemnation of private property and an advocacy of communism among the faithful, but this was only an ideal, and private property was early recognized as a necessity resulting from the fall of man. The effect of this ideal, however, appears in the accepted doctrine that the maintenance of the poor was not a matter of philanthropy, but an obligation. The Scriptural attitude toward wealth led to an emphatic statement of the moral superiority of agriculture and handiwork over trade and commerce as a means of earning a livelihood, and the early writers seemed almost unanimous in the belief that what the seller made by trade the buyer necessarily lost. With the increasing temporal power of the Church and the great development of commerce which marked the eleventh century, came the necessity of harmonizing the doctrines of the Church with the obvious requirements of commerce, and many concessions were made by the later canonists. Thomas Aquinas (c.1226-74), the most authoritative of the later mediæval canonists, concedes that it is lawful to trade for a simple livelihood, or in order to supply a country with necessary articles which it does not produce within its own borders, or when the profits of the trade are devoted to some honorable purpose such as the assistance of the poor, but that, save in exceptional circumstances, a seller is bound to reveal a fault in an article, and that it is not permissible to sell an article for more than its worth. The fundamental axiom, in accordance with which all these conclusions are reached, is that every commodity has a fixed and objective value, which can be readily ascertained, and which determines its just price. To ask more for an article than its just price was extortion, and to pay less was equally unjustifiable. The distinctively ethical viewpoint of the canonists is shown in the prohibition of usury (q.v.). This was based upon the Scriptural injunctions against usury, and upon the Aristotelian argument that, money being barren it would be extortion to charge for its use. Another favorite argument was that interest was pay for time, but time is barren, and hence to demand interest was to demand something for nothing. It is needless to add that, as the growing commerce of the Middle Ages made the need of borrowing capital more and more imperative,

the canonical theory was stretched so as to accommodate many ingenious forms of contract for what was practically, though not nominally, usury. In the latter half of the fifteenth century the Franciscans themselves instituted the *monts de piété* (q.v.), or charitable banks for loaning money to the poor, and a small interest rate was imposed in order to defray the expenses of management. By the middle of the sixteenth century the Church had practically abandoned its effort forcibly to suppress avarice and the pursuit of wealth.

THE MERCANTILISTS (1500-1750). Mediæval economic theory had been dominated by ethical considerations; the economic thought of the early modern period was dominated by political necessities. Both the feudal system and the temporal power of the Papacy had been undermined by the growth of the great modern monarchies. The problems and needs of the national States absorbed the best thought of the age. The most pressing problem of the new national governments was how to secure greater revenue. Philosophers and publicists, who would not have stooped to the elucidation of the laws of private wealth, bent their best energies to the solution of problems arising out of the establishment and maintenance of particular States. The problem of the economic thought of the period was, however, a larger one than the mere raising of the public revenue. It was requisite that this revenue should be secured in that form—ready money—which is most easily transformed into armies, navies, and the other material embodiments of national power; and the problem included, in addition, the necessity of finding or creating some more productive source of taxation than the backward agriculture of the period. With the problem of the Mercantilists plainly before us, it is easy to understand the characteristic features of the mercantile system which are described under that title. "Mercantilism," says Schmoller, "in its innermost kernel is nothing but State-making—not State-making in a narrow sense, but State-making in the modern sense, which creates out of the political community an economic community." The restrictive regulations, discriminating laws, and State interference which Adam Smith and his immediate successors described as the essential features of mercantilism, we now know to have been in a sense incidental. State interference was distinctly a minor consideration, minor in the sense that it was not the problem at issue. Moreover, the mercantile system resulted not in a loss, but in a net gain of industrial freedom. Contemporaneously with the imposition of those external restrictions which mark the mercantile economy went a rapid and extensive abolition of internal restrictions which had been far more numerous, brutal, and destructive than the new external regulations which succeeded them. The economic and political unit had merely increased its size. While mercantilism is the most important phenomenon of economic thought in the sixteenth and seventeenth centuries, it constituted only a part of a widespread and eager investigation of concrete economic facts. It was these studies which gave the political economy of Adam Smith its rich content of concrete phenomena. Money, banking, the rise of prices, population, poor relief, etc., were all extensively discussed in brochures and monographs. The maintenance

of the poor was a constant subject of pamphlet and tract, and in the communistic *Utopia* of Sir Thomas More we have striking evidence that the problem of poverty was occupying the attention of the best thinkers of the time. The study of statistics became widespread and actuarial science and the investigation of social statistics were carried really to an advanced point. Neither is it correct to refer, as many have done, to the writers of this period as empiricists. Economic study had been divorced from ethics and theology, it is true, but at the hands of Bodin, Grotius, Pufendorf, Hobbes, and Locke, economics was developed as an essential part of a general political philosophy. In the *De Jure Belli et Pacis* of Grotius (1625), particularly, the whole mercantile system is in reality brought to judgment before the greater doctrine of international equity, and we have a new application of the old doctrines of natural law and natural liberty, doctrines which were destined to play a greater rôle in modern economic science than the whole mercantile system.

THE PHYSIOCRATS. Mercantilism had been marked by a narrow favoritism of commerce and manufactures; a reaction in favor of agriculture was inevitable. The mercantilist doctrine had been characterized also by an enthusiastic, though not less narrow, nationalism; it was natural, then, that the reaction in favor of agriculture should ally itself with the broad principles of natural law and liberty expounded in the works of Grotius, Pufendorf, and Locke. This reaction in favor of agriculture and industrial liberty found expression in the doctrines of the so-called Physiocrats (q.v.). The rise of the school be dated from Quesnay's first economic monograph, which appeared in 1756. As is implied in their name, the fundamental doctrine of the Physiocrats is the subjection of economic and political phenomena to 'natural law,' which as interpreted by them gave rise to the familiar political doctrine of radical individualism, and a certain materialistic conception of wealth which explains in a way all their peculiar economic theories. As Adam Smith noted, the Physiocrats treated not only of political economy, "but of every other branch of the system of civil government," and their political and economic theories were indissolubly fused in their general doctrine of a beneficent natural law of industrial freedom, according to which the largest production and justest distribution of wealth would be best secured by permitting each individual to 'pursue his own interest in his own way,' so long as he did not infringe on the like liberty of others. This theory, perpetuated and popularized by Adam Smith, has exercised probably more influence upon subsequent thought than any other economic doctrine ever formulated.

While the Physiocrats fully exposed the error of confusing wealth with the precious metals, they themselves fell into the error of confusing wealth with material objects. Identifying the production of wealth with the production of raw materials, they concluded that manufactures and commerce, which merely change the position or form of raw materials, are barren and unproductive, though useful and desirable when strictly subordinated to agriculture; that the value added to raw materials in the processes of trade and industry is equivalent merely to the cost or expenses of production, while agriculture

yields a net surplus—*produit net*—over and above the expenses of production. To Quesnay, however, the large agricultural employer, not the agricultural laborer, was the real producer of wealth; and the physiocratic theory is especially strong and advanced in its analysis of capital. Agriculture being thus the sole ultimate source of national revenue, simplicity, economy, and justice demanded that the revenue of the State should be raised by a single direct tax—the *impôt unique*—levied upon rent. (See SINGLE TAX.) The Physiocrats must accordingly be credited with the first statement of the epoch-making theory of surplus value, the theory that the product of industry contains a certain fund of value, due to the coöperation of natural factors, which is in excess of the minimum remuneration required to elicit the toil and sacrifice of industry, and which constitutes on this account an exceptionally satisfactory source of taxation.

Adam Smith, whose *Wealth of Nations* appeared in 1776, is easily the foremost figure in the history of economic thought. Next to his influence in hastening free trade and in popularizing and dignifying the systematic study of wealth, Smith's most important service, perhaps, was in divorcing political economy from ethics, and in part from politics. This appears plainly from the outline of his lectures, which were divided into four parts: I. Natural Theology; II. Ethics—incorporated in his *Theory of Moral Sentiments*; III. Justice or Jurisprudence; IV. Political Economy. He has been charged with the mistake of treating man as merely a wealth-seeking animal in whom the altruistic motives are wholly absent; but this criticism neglects the fact that in his *Theory of Moral Sentiments* the motives of duty and sympathy are accorded full recognition, and the desire for wealth is treated as only one of the worthier objects of ambition. Even in the *Wealth of Nations* he opposes piece-work as calculated to incite the laborer to over-exertion, and voices the necessity for rest, diversion, and even 'dissipation.' His whole attitude in the *Wealth of Nations* is essentially this: Assuming that the object of the study is to increase the national wealth as much as possible, this object will be most effectually secured by perfect industrial liberty. He left the prior question of the desire for wealth to the *Theory of Moral Sentiments*. On the other hand, he did not succeed so well in separating politics from economics. He could not get without the bounds of political philosophy, because his ultimate purpose was to prove the supreme efficacy of the doctrine of *laissez-faire*. Yet before he could lay down maxims for the increase of wealth, it was necessary to inquire how wealth was actually produced and distributed, and in doing this disinterested work of science he ceases to be the advocate. It was this passionless analysis of production, value, and distribution which had the greatest effect upon the economists who followed him and led to the attempt to formulate a non-partisan science of political economy, which should pass no ethical or political judgments. It must never be forgotten that Adam Smith was not wholly consistent in the development of his theories. At times he seems to hold that education should be left wholly to private initiative, but again he classes it among the neces-

sary functions of government. In places he seems to hold a brief for 'perfect industrial liberty,' yet he does not hesitate to recommend the State regulation of banking, and his characterization of the Navigation Act as "perhaps the wisest of all the commercial regulations of England"—purely on political grounds—is famous. This inconsistency, which was in reality owing to breadth of thought, shows itself in his method of investigation. Whether it was inductive or deductive has been the subject of wide and animated discussion. Whatever the truth in this matter, the fact remains that at the hands of the economists who immediately succeeded him the science itself became increasingly theoretical, increasingly deductive and abstract. The most potent single quality of Smith's work which contributed to these results was its so-called 'universalism.' His work dealt with the wealth of nations, not that of a particular nation, or a particular epoch, and his confidence in the existence of a natural law of universal applicability left an indelible impression upon subsequent thinkers. Granted the existence of such a law, the conditions of time, place, race, and nationality must be matters of secondary importance. The superiority of the deductive method naturally follows.

THE CLASSICAL SCHOOL. The economic thought of the early part of the nineteenth century was dominated by a group of writers including Bentham, Malthus, J. B. Say, Ricardo, McCulloch, James Mill, and others, who have been variously designated as the Classical, Orthodox, Ricardian, or English School. The leaders of this school differed upon points of economic doctrine, but the general system of thought developed by them is strikingly harmonious: deductive in method, pessimistic in tone, utilitarian and materialistic in its assumptions, and cosmopolitan in the sense that its ultimate scientific ideal was the discovery of universal economic laws applicable to all nations at all times.

Jeremy Bentham (1748-1832) gave the classical economy its ethical framework through his formulation and tireless propagation of the utilitarian philosophy. Utilitarianism in its early form was largely an application to ethics of the individualistic doctrine of self-interest which Smith and the Physiocrats had applied so skillfully in the field of political philosophy. "To obtain the greatest portion of happiness for himself is the object of every rational being," says Bentham.—All that was materialistic, pessimistic, and mechanical in the classical system of political economy seems to have been magnified and intensified by the famous *Essay on the Principle of Population* by Malthus (q.v.), who in his fondness for the historical method of research was in marked contradistinction to the men about him. But his favorite method had little or no effect upon the classical political economy, while his famous doctrine that population tends to increase faster than food became the very backbone of the classical economy and modified almost every department of human thought. It may, indeed, be said that while Adam Smith investigated the causes of the wealth of nations, Malthus gave an exposition of the causes of poverty, and the contrast is not unfair. The one was essentially an optimist, the other, if not himself pessimistic, certainly gave a more pronounced impetus to pessimistic tendencies than

any other economist in the history of the science. From the scientific standpoint, the most important use made of the Malthusian proposition was in the Ricardian theory of distribution.

David Ricardo (1772-1823) held that as a country grew and population increased society would be forced to resort to poorer and poorer soils to obtain its supply of food, the *law of diminishing returns* would set in, and as the margin of cultivation was forced down an increasing share of the product of industry would go to the landlord in the shape of *economic rent*—the difference between the natural productivity of the better land and the worst land in cultivation. Excluding rent, the division of the remainder of the product between the laborer and the capitalist was determined by a corollary of the Malthusian principle—the ‘iron law of wages.’ In the long run, Ricardo held, wages would tend to equal the cost or price of the food, necessities, and conveniences required for the support of the laborer and his family in their accustomed style of living. Profits, naturally, consisted of the product minus rent and wages; they were ‘the leavings of wages.’ Ricardo’s theory of ‘progress,’ then, is clear. With the passage of time and the settlement of the country, rent would absorb a larger share of the produce, increasing both absolutely and relatively; wages would absorb a larger share, increasing relatively, but remaining constant in amount (with a tendency, however, to decrease as rents rose higher and higher); while profits would necessarily decrease both absolutely and relatively. This theory of distribution was developed as an integral part of his famous *cost of production theory of value*, i.e. that commodities will tend to exchange in quantities proportional to the respective expenses of producing them. In stating this theory Ricardo at times spoke as if all the expenses of production could be resolved into the toil and sacrifice of labor—commodities, he was fond of saying, tend to exchange for each other according to the respective amounts of labor embodied or realized in each. He thus supplied the socialists with their celebrated labor theory of value, according to which labor is the sole cause of value, and in consequence is entitled to the whole produce of industry. To a great extent Ricardo molded the economic thought of the day, and has greatly influenced the later economists. The socialists took from it, illogically perhaps, the iron law of wages and the labor theory of value. Henry George took from it, but logically in this case, the doctrine that progress itself means poverty so long as private property in land is permitted. Finally, Ricardo’s theory shifted the centre of economic interest from the land-owning classes to the capitalist class.

ENGLISH POLITICAL ECONOMY SINCE RICARDO. The narrow scope, the deductive method, and the theoretical nature of the classical economy were all intensified and formally indorsed by N. W. Senior (1790-1864), the most influential English economist between Ricardo and the younger Mill. Within the limits of classical economics Senior did notable work; he cleared up many of the latent obscurities in the Ricardian theory of distribution, propounded the abstinence theory of interest, and formulated the famous *doctrine of the wages fund*. (latent in the work of Smith, Ricardo, and others) that the

average rate of wages is the quotient secured by dividing the number of workmen into the fund of capital set aside by the capitalists for the employment of labor. With the exception of the Malthusian principle, this doctrine probably contributed more than anything else to make political economy the ‘dismal science.’ Senior is remarkable also for his exposition of the extent to which the monopoly element enters into ordinary economic life. Under perfect competition, he declares, prices of commodities would accurately measure “the aggregate amount of the labor and abstinence necessary to continue their production.” But he points out repeatedly that differential advantage of any kind in production gives rise to a monopolistic rent, which includes all income obtained without a proportionate sacrifice of labor or abstinence. In his abstinence theory Senior deprived the socialists of much of the comfort offered them in the classical economy, but in his analysis of monopoly he clearly defines the element in distribution which supplies them with a real grievance.

John Stuart Mill (1806-73) typifies the transition in England from the classical to the modern system of economic thought. He began his career as a Ricardian of the Ricardians, but in the later years of his life he came under the influence of Auguste Comte and the socialistic thought of his time, and in 1848 his principal economic treatise appeared under the title *Principles of Political Economy with Some of Their Applications to Social Philosophy*—a queer compromise between the Ricardian economics, which he had learned in his youth, and the warm desire to find some means to improve the condition of the masses, which had come to him from the observations of his maturer years. The compromise was not fortunate from the standpoint of logic. Most economists since Mill, and Mill himself in his later years, recognized that the book was inconsistent; but it was superbly written, alive with the desire to improve the condition of the masses, and exercised an enormous influence upon the subsequent development of English economic thought. The modifications of the old doctrine which Mill introduced exercised probably a greater influence than the old theories which he incorporated in his *Principles*. He preserved the old doctrines of rent and profits, and advocated *laissez-faire* as a general principle of political expediency, but made so many exceptions that at times they seem more important than the rule. Mill also indorsed the doctrine of the wage fund; but in his later years he abandoned his belief in this theory, and advocated “views of the taxation and regulation of inheritance and bequest which would break down large fortunes and bring about a wider diffusion of property.”

The development of English economic thought since 1850 has been profoundly affected by the reaction against the classical system described below, and only a few words can be devoted to the subject here. The logical successors of Ricardo and Senior were Cairnes, Bagehot, and Fawcett (to whom might be added Professor Marshall of Cambridge). It is impossible to characterize at length the work of these men, but all have been ardent defenders of the orthodox school, though they have recognized and ably expounded its limitations as a theoretical science. They stand as the modern defenders (Fawcett an

extreme partisan) of the deductive type of economic theory. In Thorold Rogers, Cliff Leslie, Arnold Toynbee, and Professors Ashley and Cunningham we have a group of historical economists, all of whom have made important contributions from the historical standpoint and who have indorsed more or less completely the general views of the Historical School (see below). Jevons stands at the head of what might be called a psychological school of political economy, of whom perhaps the most distinguished living British exponents are Professor Edgeworth of Oxford and Professor Smart of Glasgow. Both Jevons and Edgeworth, however, have made important contributions in every branch of the science, particularly that of statistics; and the attempt to classify such men as Bagehot, Jevons, Marshall, Edgeworth, and Nicholson reminds us forcibly that the period of schools has fortunately passed. The representative English economists, like those of every other country, make the most of all schools and methods: deductive, historical, psychological, statistical, and mathematical.

MODERN REACTIONS AGAINST THE CLASSICAL SYSTEM. SOCIALISM. It is a striking tribute to the classical system of political economy and to the intellect, power, and personal excellence of its leaders, that the development of economic thought since 1850 can best be understood and described as a series of reactions against the dominant doctrines of that school. The earliest and most passionate protest against the classical economy came from the socialists. (See **SOCIALISM.**) The antagonism between socialism and the classical economy is fundamental and irreconcilable. The foundation of the latter was *laissez-faire* and its theories were built around the system of private capitalistic enterprise; while socialism is in essence a protest against *laissez-faire* and the private ownership of capital. The rise of modern socialistic doctrine may conveniently be dated from William Godwin's *Inquiry Concerning Political Justice* (1793), although Godwin himself was inclined toward anarchism; but the chief bond uniting the early socialists was their common hatred of the orthodox political economy. In recent times, largely under the influence of Karl Marx (q.v.), socialism has acquired a positive theory which is adopted with substantial unanimity by the great mass of people who may correctly be called socialists. Logically enough, this 'scientific socialism' has its roots in the Ricardian theory of value and distribution. Mutilating his theory of value and interpreting it ethically, they claim that, as labor is the sole cause of value, the laborer is entitled to the whole produce of industry. They accept a part of his gloomy law of wages, magnify the class antagonism inherent in his theory of distribution, and glory in the pessimism which unconsciously pervaded his analysis. On the basis of a broader historical survey than Ricardo permitted himself to make, they confidently assert that the régime of capitalism is but a temporary stage in industrial evolution, and that it must inevitably give way to a régime of collective production. Marx's theory of value has met little but criticism from the economists, but his doctrine that the underlying causes of all social phenomena, such as religion, literature, and art, are economic in character, called by him the materialistic conception of history, has profoundly influenced the

science, particularly in Germany. The chief office of the socialists has been to arouse sympathy for the classes of society whose condition is such as to make socialism attractive to them.

THE SOCIOLOGISTS. To the sociologists may be ascribed the most fundamental and inclusive protest against the methods of the Classical School. The Ricardians aimed at an abstract science of rigid precision, universal in application, raised above the limitations of particular epochs and national boundaries. They were thus led to neglect history, custom, law, and ethics; they spoke as if the existing stage of economic development was permanent, and their method of treatment was predominantly deductive. The most effective protest against these exaggerations was made by the Historical School, which will be noted hereafter; but a more fundamental protest, and one prior in point of time, was made by Auguste Comte (1798-1857), the father of modern sociology. He exercised great influence in shaping the methods of political economy and marking out its particular place among the social sciences. The influence of sociology upon modern economic thought will be discussed more fully in the article **SOCIOLOGY.**

THE HISTORICAL SCHOOL. The most influential reaction against the classical economy was that inaugurated by what is known as the Historical School of Germany, and is usually dated from the work of Lorenz von Stein, *Der Sozialismus und Communismus des heutigen Frankreichs*, written in 1842, or, more correctly, from Wilhelm Roscher's *Grundriss zu Vorlesungen über die Staatswirtschaft nach geschichtlicher Methode*, published in 1843. Two contemporaries of Roscher, Bruno Hildebrand and Karl Knies, must be associated with Roscher and Stein in the introduction of this method, which has transformed economic science in Germany and profoundly affected it the world over. The characteristics of the Classical School which these writers most earnestly attacked were what have been called its cosmopolitanism and its perpetuism—the belief in economic laws valid for all nations and all times. The positive doctrines of these writers, briefly summarized, maintain the propositions that economics is a social or political science which can be profitably pursued only in connection with the other sciences of social or political life, particularly administration, law, and history; and that not only are economic phenomena conditioned by general social and political institutions, but that these institutions are products of an ordered historical development, so that the economic science of any particular nation can only be studied and formulated in connection with the historical development of that nation. Thus instead of a universal political economy we have an historical national economy. The work of the Historical School must be regarded as the most important movement of economic thought in the latter half of the nineteenth century, but only a few words can be devoted to its rise and development. From the standpoint of method it was simply an application to economic investigation of a method that had been developed and popularized by Grimm, Savigny, Eichhorn, and other German investigators in philology, history, and jurisprudence, a generation before the rise of the Historical School of political economy. What may be called the nationalistic spirit of the school

was the result of irresistible political forces of the day, first expressed in the economic publications of Friedrich List (1789-1846). Germany was in the process of developing into a great empire, and, as has been pointed out in connection with the mercantile system, such a period in the life of a nation is almost invariably attended with protective legislation designed to make the new State industrially, as well as politically, independent and homogeneous. The new German economies simply voiced these economic and political tendencies, to which attention had been called by List. The work of the German economists who succeeded Roscher, Knies, and Hildebrand has been marked by a predominant use of the inductive method and a close adherence to actual economic phenomena; by special study of the effect of legal institutions, custom, law, and ethics upon economic phenomena; by an intermediate attitude between extreme protectionism and extreme free-trade views; and by a discriminating sympathy with the claims of socialism. Quite generally they look to the State rather than to individual initiative to solve the problem of poverty, and they have thus become known as *Kathedersocialisten* (socialists of the professorial chair), or State Socialists, as contrasted with the Social Democrats, whose radical programme they refuse to indorse.

The American reaction precedes in point of time the National Oekonomie of Germany, and, like the latter, had its source in the political problems attendant upon the rise of a new State. The first systematic protest came from an early group of publicists, among whom may be mentioned Alexander Hamilton, Daniel Raymond, Matthew Carey, Hezekiah Niles, and Friedrich List. Daniel Raymond is the author of the first treatise on political economy in which a distinctively American system was advanced. His first work, *Thoughts on Political Economy*, appeared in 1820, and undoubtedly attracted a good deal of attention in certain circles. The fundamental idea of Raymond's system is his conception of wealth. Wealth, he held, is not an aggregation of exchange values, such as Adam Smith had conceived it, but the capacity or opportunity to acquire the necessities and conveniences of life by labor. The English political economy, he held, was a study of exchange values, of private economy as opposed to national economy, and the laws of wealth laid down by Adam Smith were untrue of a nation conceived as a unity. Extending his doctrine of wealth, he maintained that the interests of one class do not always coincide with the interests of the nation as a whole, and that national wealth in its true sense will be most rapidly increased by developing all the national powers to their widest possible extent. He is, thus, a warm advocate of protection as opposed to the doctrine of *laissez-faire*.

We come to a second period of development in American economic thought with Henry C. Carey (1793-1879), by far the most influential of the earlier American economists. Carey's work is especially noteworthy, not only for his earnest defense of protection, but for his economic optimism and his continued attacks upon the Ricardian school. Drawing his lessons from American experience, he flatly denied the Malthusian principle and the law of diminishing returns. Carey's position upon these points was

undoubtedly well taken for the America of his time, and although it is questionable whether he was justified in defending the exact converse of these propositions, he did unquestionably show that the fundamental premises of the classical economy were not universally applicable. Carey defended a broad social conception of wealth similar to that held by Raymond, defining it as the measure of power which man has acquired over nature, while "the value of an object expresses the resistance of nature which labor has to overcome to produce the object." Carey thus was led to propose the theory that the value of an object depends rather upon the cost of reproduction than the cost of production. Perhaps the central doctrine of his system is that of association. The increase of wealth, the increasing mastery of man over nature, the development of a nation's powers, Carey held to be dependent upon the increasing association resulting from a compact population following diversified pursuits with a close interrelationship between agriculture and manufactures. It was this optimistic belief in the possibilities of increased association that led him to advocate protection and to survey an increasing population with the greatest complacency. Since Carey's time, other American economists, like Henry George and Francis A. Walker, have exerted a world-wide influence upon economic thought. The younger generation of American economists have been largely trained in the German universities, and have in the main accepted the positive doctrines of the German Historical School. Without depreciating the work of the great English economists it may be said that American investigation is marked by the attempt to test and supplement deductive reasoning by an appeal to statistics, law, and history. In a typical American university the specialist in economic theory works harmoniously with associates whose special domain lies in economic history, statistics, finance, or the practical problems of the day. All methods are acknowledged to be useful, and all are employed. The period of criticism has given way to a period of construction; but American economic thought is still profoundly affected by the optimism and what may be called the anti-cosmopolitanism of the early American reaction.

THE AUSTRIAN SCHOOL represents a reaction within the limits of the classical economy itself. The name Austrian School is used simply because the marginal utility theory of value, which constitutes the essence of this reaction, has been most thoroughly developed and most widely applied by a group of Austrian economists, including Professors Menger, Wieser, Sax, and Boehm von Bawerk; though the theory itself was propounded almost simultaneously in 1871 by Professor Jevons in England and Menger in Austria, and is now used by a large majority of economists everywhere. The adherents of this school hold, in brief, that the utility (i.e. power of satisfying want) possessed by a commodity decreases per unit as the amount consumed increases, and that value itself is, or expresses, the utility of the last or marginal increment of the commodity supplied for consumption. It cannot be doubted that they have transformed economic theory; the old unit of real value—the pain and sacrifice of labor—has given way to a unit of utility; and the cost-of-production theory of exchange has been replaced by a wider concep-

tion which holds that value determines the expenses of production rather than the expenses of production value, that capital receives its value from the finished product, and not *vice versa*, etc. The whole tendency of this theory (see VALUE) has been to shift the centre of gravity in economics from the capitalist to the consumer and to block the movement to confine political economy to a study of exchange value. It has undoubtedly clarified our general conceptions of wealth and exchange much in the same way that the theory of evolution has clarified our general conception of progress.

SCOPE AND METHOD. RELATION OF POLITICAL ECONOMY TO SOCIOLOGY. The most inclusive and fundamental question of scope is the relation of political economy to the general science of human association. Two extreme views of this relation have been maintained: (1) that because of the intimate and inseparable connection between all forms of social activity, the study of economic phenomena cannot be divorced from the general study of sociology (e.g. Comte, H. von Scheel, Ingram); (2) that political economy is an absolutely independent science, dealing with the phenomena of wealth alone (e.g. Senior, Mill, Cairnes). At the present time there is a strong consensus of opinion that both these views are ill advised. While it is now admitted with practical unanimity that political economy is a social science, the bewildering complexity of social phenomena, together with the slow progress of sociology conceived as the general science of human association, has deeply strengthened the conviction, borne out in other departments of scientific investigation, that specialization and the isolation of phenomena are indispensable.

THE RELATION OF POLITICAL ECONOMY TO ETHICS, LAW, AND POLITICS. In discussing this question attention may be confined largely to the relationship between ethics and political economy, since the decisive arguments apply to all three relationships. Substantial unanimity exists upon the following points; (a) that ethics and economics are, for purposes of investigation at least, two distinct sciences; their fields are not coextensive; (b) in applied political economy we must take account of ethical requirements; no economist would maintain that in actual life men are "freed from the ordinary obligations of justice and humanity;" (c) in so far as ethical forces affect economic activity, economic science must take account of these forces. The point at issue is the question whether the scientist, as scientist, is permitted or compelled to set up ideals and pass ethical judgments. The following reasons may be given for the conclusion that it is practically impossible for the scientist to abstain from passing ethical judgments: In the first place, every rational adult understands and accepts certain axiomatic ethical canons which in their practical application are universally accepted (e.g. that the satisfaction of hunger is a good thing). In the investigation of actual economic phenomena, such as the housing and food of the laboring classes, conditions are constantly met with that violate these ethical canons. It would be the sheerest pederasty under these conditions to refrain from passing ethical judgments. Secondly, an essential part of economic science is that subdivision which treats of economic progress. In economic life what ought to be done is intimately dependent upon what

can be done; in other words, the law of economic growth is a powerful, if not the most powerful, factor in determining economic aims and ideals. If the fully equipped economist is forced to study economic growth and to explain economic movements and tendencies, it follows that he is forced to express opinions upon approximate economic ideals, and after having furnished the decisive arguments for ethical judgments, he must either apply his results or have some less qualified person apply them for him. Additional reasons appear when we examine such subjects as taxation or those public prices which the law declares must be just and reasonable. In the consideration of railroad rates, for instance, the economist is not only compelled to pass judgment upon what is just and reasonable, but he discovers upon investigation that economic considerations supply the most important factors in determining this judgment. There is, then, a broad zone of territory between ethics and economics which the moralist has not worked—and which for the science of ethics is probably unimportant—but which the economist must clear up before he can go on with his work. The assertion that the science of political economy may and should refrain from passing ethical judgments rests upon two misapprehensions: (1) the failure to grasp the fact that society is like an organism in that it is subject to a law of ordered change, which to a certain extent is under the control of the organism itself; (2) an illogical conclusion from the recognized truth that certain subdivisions of economic investigation (e.g. fixation of prices in wholesale markets) may be exploited quite thoroughly without determining economic ideals, and without introducing ethical considerations. From this it is logical to conclude that certain minor subdivisions of political economy may be investigated "without passing ethical judgments," but illogical to conclude that the whole science may be so investigated and formulated. The above conclusions are strengthened when we consider the relation of economics to law or politics. In describing the progress of the past or the conditions of the present we are forced to pass judgment upon the economic success or failure of many laws and policies (e.g. tariff laws) which are still in force or under active consideration, and which will be indorsed or repudiated solely or largely upon economic grounds. Because of this fact the economist cannot refrain from judgment upon laws and political policies. Nor without being ridiculous can he refrain on occasion from laying down precepts. Gresham's law, for instance, is at once a law and a precept when a proposition to maintain a more valuable and a less valuable money side by side in circulation is under consideration. In conclusion it may be said that while political economy does not undertake the complete study of law, ethics, politics, etc., it must consider systematically the parts of those sciences which materially affect economic phenomena. It is neither possible nor desirable that the line of demarcation should be rigidly drawn, particularly in the applied science or art of political economy, which may be defined as the application of economic laws to the solution of those practical problems in which economic considerations are of predominant importance.

RELATION TO OTHER SCIENCES. Political economy is probably more dependent upon history than

upon any other science, and indeed an extreme wing of the Historical School, of which Schmoller is the most prominent example, holds that until a larger store of historical results is accumulated it is of little use to attempt broad theoretical generalizations; thus confining economics for the present to the philosophy of economic history. This position seems untenable because of the evident logical deficiencies of the historical method when used alone, and because new problems are constantly arising upon which history throws little light. (See *Deductive Method*, below.) While the great majority of economists refuse to admit that political economy is merely history, the importance and necessity of economic history are now universally conceded. Dr. Keynes classifies the functions of economic history in connection with economic theory as follows: "First, to illustrate and test conclusions not themselves resting on historical evidence; secondly, to teach the limits of the actual applicability of economic doctrines; thirdly, to afford a basis for the direct attainment of economic truths of a theoretical nature."

The connection with psychology is particularly intimate. As a study beginning with human effort and ending with the satisfaction of human wants, economics really has its beginning and end in psychology. The theory of value, particularly, takes its fundamental axioms from psychology (e.g. that the satisfaction afforded by commodities decreases per unit as the amount consumed increases). The difference between economics and psychology is, however, clear: the one deals with man in society, the other with man as an individual.

THE DEDUCTIVE METHOD. What is known in economics as the deductive method consists usually of three stages, the first and last of which are inductive. In the preliminary stage, either from common observation or more complex induction, the *postulates* of the deductive science are secured. In the English economic theory prevalent from Ricardo to Cairnes these postulates were excessively simplified. Ricardo, like Adam Smith, was fond of drawing his premises from an imaginary state of primitive industry. Senior reduced the postulates of political economy to four general propositions: "(1) That every man desires to obtain additional wealth with as little sacrifice as possible. (2) That the population of the world is limited only by moral or physical evil, or by fear of a deficiency of those articles of wealth which the habits of the individuals of each class of its inhabitants lead them to require. (3) That the powers of labor, and of the other instruments which produce wealth, may be indefinitely increased by using their products as a means of future production. (4) That, agricultural skill remaining the same, additional labor employed on the land within a given district produces in general a less proportionate return." It is impossible to give a list of the postulates which have been assumed by different writers, but it is evident that they must vary widely in different branches of the science, and that almost every deductive writer has unconsciously assumed many postulates not specifically stated. In the ordinary deductive treatment of value and distribution there are usually postulated the propositions that men not only desire, but know how in

general to obtain the maximum satisfaction with the minimum effort; that certain industries are subject to the law of increasing rather than diminishing returns; that the satisfaction afforded by a commodity decreases (per unit) as the amount consumed increases; that existing law, public opinion, and ethical standards, in general remain constant. It is the intermediate stage which is most appropriately called deductive. Here the familiar processes of the deductive logic are employed. It is evident, however, that the results obtained from the artificially simplified premises of ordinary deductive theory are of doubtful value. If the postulates be absolutely true and the deduction faultless, the conclusions express abstract tendencies which will be modified in real life by the action of secondary forces not taken into account in the premises. This, however, is the character of the pure theory of all sciences. If, on the other hand, the premises practically cover the predominant forces in any domain of economics, they may yield results capable of explaining actual economic conditions, and capable of affording the basis of prevision. In actual usage, however, these postulates have been sometimes untrue, often ambiguous, and always more numerous than was explicitly stated, so that Cliff Leslie and other writers of the Historical School have characterized the conclusions of English theory as utterly inapplicable in any sense either to the explanation of existing conditions or the solution of practical problems. This extreme antipathy to deductive theory is, however, plainly illogical. Whatever the necessity of studying the past, no one denies that the present and the future furnish the ultimate and principal problems of the science. And many of these problems are new; to solve them we must isolate the factors at work, calculate separately their effects, and try to estimate the net results. This process must be largely deductive, and it is strange that those who insist most strenuously that the science is a practical one should attack a method necessary in the solution of practical problems. The historical method alone is helpless in the face of such a problem as the proposition to introduce compulsory arbitration.

Of the third stage in the deductive process, that of verification by observation, little need be said. In practice it is exceedingly difficult, as was shown when Mill attempted to "apply" the Ricardian theories, but it is essentially a species of induction subject to all the limitations of the inductive method in general.

THE INDUCTIVE METHOD. The ultimate aim of the inductive method is by systematic analysis and comparison of concrete economic phenomena "to observe the effects of a cause coming singly into action while all other forces remain unaltered." The attempt to do this gives rise to two inductive processes: the method of difference and the method of agreement. In the method of difference we compare circumstances exactly similar with the exception of one factor, in order to discover the effect of that factor. Thus, in 1893, Messrs. Mather and Platt, of the Salford Iron Works, attempted to discover the effect of the eight-hour day on their profits and the general welfare of their workmen. Strictly speaking, their experiment required that, with the exception of the hours of labor, every causal

condition in 1893 should be identical with those in preceding years, as their object was to discover the exact effect of the reduction in hours upon profits and conditions of employment. The chief instrument of the method of difference is thus the experiment, to which may be added in economics the observation of extraordinary instances in which the conditions of an experiment are closely approximated by some fortuitous or extraordinary event. Thus the Black Death in England furnishes a striking exemplification of the effect upon wages of a sudden diminution in the supply of labor. In theory the method of difference requires that the collateral or surrounding circumstances shall be absolutely alike. This condition is seldom fulfilled even approximately, and hundreds of instances might be cited in which the method has been abused. To refer to the experiment at the Salford Iron Works, which on the whole constitutes an ideal economic experiment, it is evident that grave doubt is thrown on the results of this experiment by the fact that the workmen themselves were interested in the success of the experiment, and probably worked with extraordinary care and diligence to make it a success. Finally, it is to be noted that the method of difference, while entirely satisfactory where the conditions are perfect, is always narrow and restricted. It shows with certainty that a given cause in a certain set of circumstances can produce a certain result, but tells us nothing of what will happen in another set of circumstances.

To generalize, to establish uniformities, use is made of the method of agreement. Here we compare circumstances wholly different, with the exception of two phenomena between which we expect to establish a causal connection. The causal connection is indicated by the repeated conjunction of the two phenomena. If we examine the movement of exports and the movement of the marriage rate, and find that a rise in the exports per capita is always accompanied by a rise in the marriage rate, we are safe in accepting this connection as an economic uniformity or law, provided that we have examined a very large number of instances in which the collateral circumstances have been infinitely diverse and varied. Theoretically this method requires that we should exhaust every possible combination of circumstances before concluding that a rise in the exports per capita will always cause an increase of marriages.

With respect to the general utility of the inductive method, it is plain that, though little can be done without it, it seldom, if ever, suffices to convince. Take the case of the exports and the marriage rates cited above. Hundreds of instances might be adduced from English statistics in which a rise in the per capita exports has been followed by a rise in the marriage rate. Yet no one believes that a mere increase in exports would cause an increase in marriage. Both are evidently the results of a single cause—active business, etc. Brisk trade, high wages, constant employment, etc., stimulate marriage and show themselves usually in an increased volume of exports, yet if commercial prosperity at any time increased without stimulating exports, we have every reason to believe that the marriage rate would rise irrespective of exports. And in less developed countries where trade and commerce are relatively unimportant no con-

nection is observed between exports and marriage. The great difficulty of induction in economics is due to the complexity of economic phenomena: we are seldom able either to bring about a satisfactory experiment or to secure a sufficiently diverse number of instances of agreement. Current literature is full of sweeping generalizations based upon far less agreement than that observed between marriages and exports. The twenty-five years preceding the repeal of the corn laws in England were, on the whole, far less prosperous than the twenty-five years which succeeded the repeal; *ergo*, concluded many writers, free trade would be advantageous to every country of the world. On the other hand, the method of agreement has been equally abused. Because the creation of the great modern European monarchies was in most instances accompanied by protective tariffs, colonization schemes, and a certain harshness and brutality toward strangers, therefore, concluded the extremists of the German Historical School, it is not only expedient, but ethically right, that the German Empire in the last half of the nineteenth century should start in with protective tariffs, colonization schemes, and the policy of the mailed fist. To-day it is universally conceded that both methods must and should be used wherever possible.

OTHER METHODS. In actual practice a large number of complicated combinations of the deductive and inductive methods are used in economics. Induction in its quantitative aspect gives rise to the statistical method. No school of political economy has ever disputed the importance and value of statistics, and in the last few years it has made more rapid progress perhaps than any other branch of the science. This is due to the increased public expenditures in statistical investigations, and the impetus given to the improvement of the study by such associations as the International Statistical Institute, the Royal Statistical Society, the American Statistical Association. So great has been the development of statistical technique at the hands of such men as Quetelet, Bertillon, Engels, Von Mayr, Edgeworth (to whom should be added from other sciences, Galton, Venn, Karl Pearson, etc.), that the technique of quantitative induction constitutes in reality a new branch of science. (See STATISTICS.) Deduction in its quantitative aspect gives rise to the mathematical method of political economy, which at the present time is employed to a greater or less extent in all branches of economic theory, particularly in the investigation of prices, incidence of taxation, etc. Opinions differ upon the usefulness of mathematics except in statistics. Mathematical diagrams for purposes of illustration, at least, have undoubtedly made a permanent place for themselves in the science, but the utility of algebraic mathematics, except for him who computes them, is doubtful.

BIBLIOGRAPHY. The most important works of the earlier English economists are: Smith, *Wealth of Nations* (London, 1776; many later editions); Say, *Traité d'économie politique* (Paris, 1803); Ricardo, *Principles of Political Economy and Taxation* (London, 1817); Malthus, *Political Economy* (ib., 1820); Mill,

Principles of Political Economy with Some of Their Applications to Social Philosophy (ib., 1848); Senior, *An Outline of the Science of Political Economy* (ib., 1850). Prominent modern general treatises are: Marshall, *Principles of Political Economy* (4th ed., ib., 1898); Nicholson, *Principles of Political Economy* (New York, 1893-1901); Ely, *Outlines of Economics* (New York, 1893); Wagner, *Lehr- und Handbuch der politischen Oekonomie* (Leipzig, 1883-1901). The new theories are best represented by Wieser, *Natural Value* (London, 1893); Boehm-Bawerk, *Positive Theory of Capital*, Eng. trans. (ib., 1892); Clark, *The Distribution of Wealth* (New York, 1899). The most important socialistic contribution to economics is Marx, *Capital* (London, 1887). Consult, also: Ingram, *A History of Political Economy* (New York, 1888); Ashley, *An Introduction to English Economic History and Theory* (London, 1888-93); Palgrave, *Dictionary of Political Economy* (ib., 1894-99).

POLITICAL OFFENSES. Acts which are considered as injurious to the safety of the State, or which involve a violation of the allegiance due from a subject or citizen to the supreme authority of a nation. Such offenses are to be distinguished from those which merely disturb the public peace, as murder, theft, and the like, and which do not strike at the Government itself.

Political offenses are now usually exempted from extradition treaties. However, England and the United States, to avoid international complications, have passed laws tending to prevent expeditions against foreign governments being fitted out within their territorial limits. The tendency in modern times is to deal leniently with political offenders. For example, although treason is nominally punishable with death in most countries, the sentence is now usually commuted to life imprisonment, as in the case of Col. Arthur Lynch, who was convicted of treason in England after the Boer War. See CITIZEN; EXTRADITION; GOVERNMENT; TREASON.

POLITICAL PARTIES. Voluntary associations or organizations of citizens for the attainment of desired ends or policies through united political action. They are found in all democratic States and all countries governed upon a constitutional basis, and are a necessary accompaniment of popular government. The Germanic nations, and especially those of the English branch, have always shown the greatest aptitude for political organization. The theory and general practice of parties among the Latin and other peoples which have followed the English race in the adoption of popular representative government is the same. Race characteristics and lack of training for self-governing institutions have, however, modified the party system in actual practice among these peoples. There is especially to be noted a tendency to split into personal factions until real issues and principles are lost sight of. The political groups in France and Spain illustrate this tendency.

Aside from local and temporary issues, there are certain natural lines of cleavage in political society which always have an influence in the composition of parties. The division between conservative and radical, with all the inter-

mediate shadings of belief, is as old as society, and underlies nearly all parties that are not mere personal factions. In the political philosophy of the world the nice balance between the conservative spirit that clings to that which is sanctioned by established usage, and the radical, progressive, or liberal spirit, which seeks modification of the old in the interest of progress, is most desirable. This end is somewhat imperfectly attained by the opposition of parties representing in some form the two ideals. This is the broadest and most universal idea that divides parties. In England, where the highly developed parliamentary government makes strong party organizations indispensable, they form almost a part of the government machinery itself, and have their chosen and officially recognized leaders by whom the party policy is voiced and directed. In other countries, although their influence upon the government is as important, their connection with it has less of an official character. Below is given a summarized account of party relations in the various European countries and Canada. Political parties in the United States are described under their historical names, as DEMOCRATIC PARTY; REPUBLICAN PARTY; WHIGS; etc.

AUSTRIA-HUNGARY. The strong national feeling on the part of different peoples embraced in the dual monarchy and the peculiar constitution of the Empire have aligned parties chiefly upon race lines. In Cisleithania are the Germans, constituting roughly one-third of the population; the Bohemians or Czechs, not quite one-fourth; the Poles, about one-sixth; several smaller Slavic groups; the Rumans; and the Italians. These are mutually jealous and antagonistic, and this fact determines the policy of the Imperial Ministry, which is, in general, to create its own party support by combining different race groups against the others. After the revolutionary movement of 1848 a period of absolutist reaction set in, which suppressed all political life for ten years. In 1861, after the failure of an attempt to reorganize the Empire on a federalistic basis, the Government proceeded to establish a constitutional system upon a basis of consolidation. In this reconstruction the aspirations of the Magyars were all but completely ignored. During the period between 1860 and 1867 the so-called Federalist Party stood for Conservatism in its strictest sense, and party government as distinguished from the Imperial policy can hardly be spoken of. After a suspension of the Constitution, the compromise of 1867 (see AUSTRIA-HUNGARY and AUSGLEICH) was arranged, establishing the present dual system. Under it party contests in Cisleithania have become more pronounced. The Germans are primarily divided into the Liberal and Conservative parties, the latter of which comprises Feudalists, bureaucratic, and, above all, Catholic elements. But the Germans present by no means a united front, even as against the pretensions of other nationalities. The Socialists represent, as in Germany, in great measure the aspirations of the liberal elements, while Christian Socialism has become but another name for the rampant party of anti-Semitism. Of late the anti-German attitude of the Catholic clergy has given impetus to the so-called "Los-von-Rom" movement, which has driven thousands of liberal Germans in Lower

Austria, Bohemia, Moravia, Silesia, and Styria into the fold of Protestantism and Old Catholicism. The nationalist groups or parties are the Czechs, Poles, Ruthenians, Slovenes, Italians, Croats, and Rumanians. Of these the most important are the Czechs. This group has its aristocratic and democratic wings, the Old and Young Czechs, who have united in recent years in a demand for the recognition of the Czech nationality through a union of Bohemia, Moravia, and Silesia as a kingdom, united with Austria only by treaty, as Hungary is, and not organically. The Austrian Slavs, with the exception of the Poles, are very friendly to Russia, while the liberal Germans naturally lean toward Germany. These are united with the Magyars of Hungary in common fear of Slavic domination. The political status of Cisleithania under these conditions is most unsettled. Its Reichsrat is notoriously disorderly, and thorough party organization is impossible. Self-interest and the popularity of the Emperor Francis Joseph II. are the two elements that keep the heterogeneous body together. For Hungary (Transleithania), see HUNGARY below.

BALKAN STATES. In the Balkan States—Bulgaria, Rumania, and Servia—pro-Russian and anti-Russian sentiment has had a principal share in the alignment of parties, especially in Bulgaria. In Bulgaria, before the union with Eastern Rumelia (1885), there were Radicals, who demanded union, and Conservatives, who were satisfied with the existing condition. After the union, in the face of Russia's bitter opposition thereto, the Radicals became anti-Russian. The Bulgarian Nationalists seek to unite all Macedonia under Bulgaria, and therein Bulgaria's interests clash with those of Greece. Rumania, of all this group of States, is the most settled in its political life. The parties are Conservatives and Liberals, the government of the parliamentary form, and the two parties have alternated in the Ministry. In Servia the parties are Liberals, who are pro-Russians; Radicals, who are pro-Austrians; and Progressists, who also lean to the side of Austria.

BELGIUM. The chief parties are two—Clericals or Catholics, and Liberals or anti-Catholics—and there are in addition the groups of Protestants and Socialists. The Protestants have slight influence in Parliament, and both these groups act with the Liberals against the Clericals. Until 1847 there was a struggle against the Crown to establish party government through a responsible Ministry. Since that year the Ministry has been taken from the majority in the Chamber of Deputies. The parties have alternated in control, but since 1884 the Catholics have held the Government and have gathered to themselves the conservative elements of society repelled by the growing political importance of the Socialists. In 1893 an active agitation resulted in the adoption of practically universal suffrage. Since that time the Liberal Party has virtually fallen under the control of the Socialists. The elections of 1902 resulted in a decided Catholic victory.

CANADA. Political parties worthy of the name made their first effective appearance after the War of 1812, in "a struggle for responsible government against the rule of an autocratic Governor and his Camarilla." Aroused by the political

monopoly and social arrogance of a group of royal officials known as the "Family Compact" (see CANADA, section on HISTORY), opposition took the shape of a Reform Party, under the leadership of Mackenzie, Ralph, Bidwell, and Baldwin, advocating an elective legislative council, reform in the administration of Crown lands, independence of the judiciary, popular control of revenue and the civil service list, and abolition of clerical reserves. The "Family Compact," rapidly enlarging into a Conservative or Tory party, under the leadership of Robinson and Strachan, was forced into a contest which resulted in a Reform victory in 1839. Under the new régime a responsible and liberal government was partially introduced, the Upper House being made elective, the Anglican Church disestablished, the clerical reserves secularized, and the University of Toronto thrown open to Nonconformists. Parties soon formed anew upon the question of "representation by population"—an attempt to remedy the unequal representations of Upper and Lower Canada as established in the Union of 1840. The Grits represented the aggressive elements, under the leadership of George Brown, and the Tories the opposition, led by Cartier and Macdonald. This new contest of parties, embittered by racial and religious differences, produced in 1864 a complete deadlock in Dominion politics and legislation. The situation was temporarily relieved by the formation of a coalition, a compromise Ministry under Macdonald and Brown, and the adoption of the much-agitated confederation of the provinces (1867). Confederation, however, soon produced new lines of party distinction rather curiously interwoven. Conservatism allied itself with Nationalism, and advocated the strengthening of the confederation. Liberalism affiliated itself with Provincialism, and decried undue interference in local affairs. In 1873-74 the Radical Reform Party succeeded in gaining control of political affairs; but in 1878, owing to its advocacy of free trade and the Conservative adoption of a 'national' or protective policy, it was again reduced to the opposition. From 1893 to 1896 the Liberals gained rapidly in popular favor. In 1896, under the leadership of Wilfrid Laurier, and by the union of their tariff policy with a radical opposition to federal interference in the noted school controversy of Manitoba, they succeeded in overthrowing the supremacy of the Conservatives. Under the new order the Manitoba school question has been settled, slightly to Liberal disadvantage; reciprocity has given way to a preferential tariff favoring England; a popular plebiscite in favor of prohibition has been disregarded, notwithstanding a prohibition plank in the Liberal platform of 1893; and labor difficulties promising in 1899 the formation of a labor party have been at least temporarily settled. The Liberals have succeeded in holding their own against the skillful opposition efforts of Sir Charles Tupper and the other Conservative leaders, carrying the elections of 1900 by decisive majorities and retaining their complete domination of the Dominion House. Much friction is introduced into Canadian politics by the race question, religious differences, and the fear or hope of American annexation. At present efforts are being made to form party lines upon the question of British imperialism, with disturbing factors in the recent

railroad and industrial combinations affecting both the United States and Canada.

DENMARK. Parties in Denmark took on a new formation after the cession of Schleswig-Holstein and Lauenburg, in 1864. Under the Constitution of 1866 the Diet was composed of two chambers, the *Folkething*, the popular representative branch, and the *Landsting*, consisting of twelve members, appointed by the King, and forty-four elected by voters possessing incomes of two thousand crowns. The Liberal-Nationalist Party, which had opposed the cession of the duchies, became a conservative landholding and official class party, controlling the *Landsting*, while the masses, represented in the *Folkething*, stood in opposition and themselves divided into the Moderate Left and the Democratic Left. An endless dispute arose over the budget between the Houses, the Democratic Left, controlling the *Folkething*, refusing to admit the veto of the *Landsting*. The Democrats lost their majority in 1891, but the conflict between the chambers is repeated when important issues arise, although of late the King and the Conservatives have practically managed the government.

FRANCE. The French Revolution, by the impulse that it gave to the growth of democracy, introduced political parties in Continental Europe. (For the revolutionary parties in France, see the articles FEUILLANTS; GIRONDISTS; JACOBINS.) With the Restoration there appeared the two monarchist parties—the Constitutional Monarchists and the Ultra Royalists. (See CHAMBRE INTROUVABLE.) There were also the Doctrinaires, Republicans, and Bonapartists. With the accession of the House of Orleans in the person of Louis Philippe, French parties underwent a readjustment. The existing monarchy was opposed by Legitimists, who sought the return of the elder Bourbon line; Bonapartists, who would have restored the Napoleonic régime; and Republicans. The Orleanist monarchy was overthrown, apparently by the Republicans (see FEBRUARY REVOLUTION), but the Bonapartists became dominant after the coup d'état of December 2, 1851. (See NAPOLEON III.) From 1852 to 1860 the Emperor exercised almost autocratic power, and politics were dormant so far as popular parties and parliamentary life were concerned. Later he lost the support of the Catholic clergy by his Italian policy, and was compelled to turn more to the Liberals. He thus reopened the active political life of France. Republicans, Orleanists, and Legitimists at once formed an Opposition. Parliamentary action was renewed. A Liberal Imperialist party supported the Emperor, but opposed his Ministers. Upon this party Napoleon depended to maintain the Empire against the Royalist and Republican coalition in 1869-70. The French defeat in 1870-71 (see FRANCO-GERMAN WAR) overthrew the Empire and presented the Republicans their opportunity. When the Third Republic rose upon the ruins of the Second Empire, the Republicans, although a minority party, found themselves in control of affairs through the lack of harmony among their opponents. Each of the three monarchical parties—Legitimists, Orleanists, and Bonapartists—recognizing its own inability to control the situation, was willing to have the Republicans temporarily in power, hoping that the next turn of the political wheel would bring in its own particular type of monarchy. In the first National

Assembly the Royalists and Bonapartists made up the reactionary Right and, united, were in a majority, while the Republicans themselves were made up of numerous and often discordant groups. There were the Extreme Left, which had few members, but a large following outside the Assembly; the Left, by far the largest group; and the conservative Left Centre, which gradually gained supporters among the moderate or constitutional monarchists of the Right Centre. Thiers (q.v.), the first President, was a constitutional monarchist who regarded the Republic as a political necessity. The Ministry was a conservative one made up from the Left Centre. The acceptance of this moderate leadership was an encouraging sign, but all unity disappeared as soon as the German occupation ended. The radical strength in the Chamber increased, and in response to its demands the Ministry was modified. The united Right was able to pass a vote censuring the change in the Ministry, and Thiers resigned, whereupon Marshal MacMahon (q.v.) was elected President as the candidate of the Right (1873). He at first appointed a coalition Cabinet from the three monarchical parties. The Right was united only in opposition to the Republicans, and the groups of the Left likewise united solely for the purpose of opposing the Government. MacMahon's term of office was made seven years (the so-called septennate). For a year and a half the different aims of the factions on both sides of the Assembly prevented action on the Constitutional Laws. In June, 1875, fearing the growth of the Imperialist strength, some of the constitutional monarchists united with the Left to secure the passage of the laws.

The Assembly created by the new Constitution consisted of a Senate and a Chamber of Deputies. The Constitutional Laws recognized the sovereignty of the people, represented in the Chamber of Deputies, and established the right of public meeting; the liberty of the press, and universal suffrage. The Republicans, with a large majority in the Chamber, forced the fighting. They were divided into the Left Centre, Republican Union (the largest group, led by Gambetta), and the Radical Left. The Monarchists, adopting a conservative attitude, were grouped as Right Centre, Right, and Popular Appeal. MacMahon in 1876 made up a Ministry from the Left Centre, at first under Dufaure (q.v.), later under Jules Simon (q.v.). In 1877, after a year of struggle against radical measures, acting under the advice of his conservative friends, MacMahon dismissed the Simon Ministry, adjourned the Chamber, and then, with the consent of the Senate, dissolved it. The Conservatives then sought to intrench themselves in the Government through the power given to the President and Senate by the Constitutional Laws, but the President had by his course opened a bitter struggle which destroyed any possibility of harmony. The Republicans won the elections, refused to recognize a Conservative Ministry, and finally forced the President to form a Ministry from the Left Centre. In 1878 the Republicans obtained a majority in the Senate, and MacMahon, unwilling longer to maintain the conflict, resigned in 1879, and was succeeded by Grévy. Their supremacy once established, the Republicans renewed their factional struggles. The Left Centre lost its influence. Gambetta's Republican Union was opposed by a growing

Radical wing, which reproached Gambetta with opportunism. A series of Ministries tending toward radicalism followed. A period of personal politics was entered upon, with Ministries combined for expediency rather than as exponents of political principles, fourteen different Ministries holding office between 1878 and 1888. The two principal wings of the Republicans came to be known as Opportunists and Radicals. The Legitimists united with the Orleanists in 1883, and two years later an increased number of monarchists were returned to the Chamber. An attempt was made in the face of this growing Conservative strength to unite the Opportunists and Radicals (policy of Republican concentration). The pretenders to the throne were banished in 1886 at the instance of the Concentration Ministry. In 1887 the Rouvier Ministry adopted the so-called policy of conciliation, which aimed at a coalition of Conservatives and Opportunists against the Radicals. In the same year General Boulanger (q.v.) came into prominence and sought to profit by the prevailing political confusion. His shibboleth, 'revision of the Constitutional Laws,' won support from all of the dissatisfied factions. His party was known as the Revisionist or National Party. The support of Boulanger by the Catholic Conservatives alienated his Radical followers, who joined the Opportunists to defeat him. In 1889 the complete overthrow of this political adventurer was accomplished. This victory was important evidence of the growing strength of the Republic.

A marked change in parties now began. The Republicans who had united to defeat Boulanger continued to act together as Moderates or Government Republicans. The monarchist parties were all weakened and discredited by their participation in the Boulanger episode. Radicalism came to be more and more represented by the Socialists. This body, hitherto of slight importance, had its origin in the break-up of the Republicans during the struggle against the July Monarchy, those who continued to uphold Republican principles seeking a purely political revolution, while a party of workingmen and theorists sought to make the Republic a means of radical social reform. In the succeeding years the ideas of the Socialists frequently found expression in the demands of the Radicals. In 1890 there were four Socialist groups, with views more or less extreme, and increasing political activity. A change that greatly strengthened the Moderates was the gradual cessation of clerical opposition to the Republic. Many Catholics who had formerly acted with the reactionary parties now came to the support of the Government under the name of *Ralliés*, or the Constitutional Right. A protective tariff with maximum and minimum rates was enacted in 1892; otherwise there was very little positive legislation during this realignment of parties, and the Freycinet Ministry (1890-92) enjoyed a hitherto almost unprecedented term of office. In 1892 there was a startling exposure of the use of enormous corruption funds in promoting the Panama Canal scheme. Over one hundred Senators, Deputies, and officials were implicated, including many political leaders, but even in the face of this the Moderates gained largely in the elections of 1893. The policy of concentration was discarded, and the Moderates took full responsibility, with Casimir-Périer (q.v.) at the head of the Min-

istry. The murder of President Carnot in 1894 was followed by the election of Casimir-Périer as his successor and drastic measures against anarchists. The new President and his Government were violently assailed by the Socialists and Radicals for their policy, the Dupuy Ministry went down in 1895 before the Opposition attacks, and then Casimir-Périer resigned the Presidency. Felix Faure (q.v.) was elected President by a union of the Moderates and the Right, but the Socialists, who had supported Brisson, had shown a significant increase of strength. The first Moderate Cabinet (Ribot) gave way in a few months to one much more Radical (Bourgeois), but the latter, after a struggle with the Senate, was succeeded in 1896 by another Moderate Ministry (Meline). The Dreyfus case (see DREYFUS) complicated French politics for three years, and even endangered the Republic. The Meline Ministry, which depended on the support of the Right, came to an end in 1898. A Radical Ministry under Brisson wrestled unsuccessfully for a few months with the Dreyfus case. A new coalition Cabinet was then organized by Dupuy. On the death of President Faure, in February, 1899, Emile Loubet (q.v.) was elected to the Presidency, and in June a new Ministry was made up by M. Waldeck-Rousseau. A Radical Socialist, M. Millerand, was included in this Cabinet. The Government took positive measures to put down the revived Nationalist agitation, imprisoning several of the old Boulangists, who had resumed their activity. An amnesty bill in 1900 purged all who were connected with the Dreyfus case. While the Government thus tried to still the strife which had injured France, it did not hesitate to bring on a conflict with the Catholic Church. This was done by the introduction of the so-called Associations Bill, regulating the privileges and rights of property of certain associations. This measure, while general in its terms, was ostensibly intended to bring within control of the common law the Jesuits and monastic communities, which had no authorization from the State, held large amounts of property, conducted numerous schools, and were directed to a great extent from outside of France. Notwithstanding Papal warnings and severe criticism at home, the measure was carried by a good majority in March, 1902, and in April the long-lived Waldeck-Rousseau Administration went to the people on its record. The result was the election of 382 Ministerialists and but 196 of all the opposition factions. After this vindication of his policy, the Premier retired and was succeeded by M. Combes, who continued his predecessor's policy and unsparingly enforced the Associations Law. When the first excitement had passed, it became evident that the Government had a powerful legislative and popular backing. A supplementary measure in March, 1903, practically refused the conduct of schools to the religious Orders, on the ground that their tendency was un-republican. This action pointed to a growing separation of Church and State in France, and the development of parties indicated the consolidation of the Republic and a more radical political condition.

GERMANY. The national parties in the German Empire have their source and their local counterparts in the separate German States. Bismarck carried his earlier measures by means of the support of a patriotic nationalist party, the

National Liberals, whose chief idea was the creation of German unity, and who were willing to support the Chancellor, although they did not wholly approve of him. He was also supported, with more enthusiasm, by the Free Conservatives (*Reichspartei*). He was opposed by the Old Conservatives, who clung to the old particularistic régime, and by the Progressists (*Fortschrittspartei*), who rejected all compromises and were the radical wing of the Nationalist Party that preceded the formation of the Empire. The *Kulturkampf* (q.v.) encouraged the growth of another strong opposition party, Ultramontane Catholic, known as the Centre. This had its strength in the Catholic States of South Germany and in the western part of Prussia. This party since 1893 has been the strongest single group in the Empire. It elected 100 members of the *Reichstag* in 1903. Bismarck, before his retirement, in view of the falling away of his old National Liberal support, had turned to the plan of a coalition between the Conservatives and his old enemies of the Centre to obtain support for the Government. The Social Democrats follow the Centre in point of numbers (82), then come the Conservatives (53), National Liberals, Radicals (*Freisinnige*), the Free Conservatives, the Anti-Semites, and a few lesser factions. The Polish elements form a strongly hostile Nationalist group. The predominance of Prussia in the Empire gives Prussian politics an overshadowing influence, and the Agrarians, who are primarily a Prussian landholders' party, opposed to the present commercial policy of the Government, and desirous of extreme protection against the importation of foodstuffs, control the Conservative members entirely, the Centrists to a great extent, and have a strong hold among the Poles and Anti-Semites. The Government is thus forced, on some of its favorite projects, to look to the Liberal groups for its support. The Agrarians were strong enough to defeat the Emperor's Rhine-Elbe canal project in the Prussian Landtag in 1899, arousing thereby very bitter feeling. This strong Agrarian agitation is a most important complication in the already complex party situation in Germany. In the Parliamentary elections of June, 1903, the Socialists polled a vote hitherto unequalled in strength.
